Numa Pompilius calling the Roman Husbandmen before him, to encourage those whose Lands were well cultivated, & reproach others with the want of Industry.

THE

COMPLETE FARMER:

Bechive OR, A GENERAL *1769*

DICTIONARY OF HUSBANDRY,

IN ALL ITS BRANCHES;

Containing the Various

Methods of Cultivating and Improving every Species of Land,

According to the PRECEPTS of both the

OLD AND NEW HUSBANDRY.

Comprising every Thing valuable in the beſt Writers on this Subject, viz. LINNÆUS, CHATEAUVIEUX, the Marquis of TURBILLY, PLATT, EVELYN, WORLIDGE, MORTIMER, TULL, ELLIS, MILLER, HALE, LISLÉ, ROQUE, MILLS, &c.

TOGETHER WITH

A Great VARIETY of NEW DISCOVERIES and IMPROVEMENTS.

ALSO

The Whole Buſineſs of Breeding, Managing, and Fattening CATTLE of all Kinds; and the moſt approved Methods of curing the various Diſeaſes to which they are ſubject. Together with the Method of raiſing BEES, and of acquiring large Quantities of WAX and HONEY, without deſtroying thoſe laborious Inſects.

To which is now firſt added,

The GARDENER'S KALENDAR,

Calculated for the USE of FARMERS and COUNTRY GENTLEMEN.

Illuſtrated with a great VARIETY of Folio COPPER-PLATES, finely engraved; exhibiting all the Inſtruments uſed in HUSBANDRY; particularly thoſe lately invented, and preſented to the SOCIETY for the Encouragement of ARTS, &c. in LONDON; many of which have never yet appeared in a Work of this NATURE.

The SECOND EDITION, CORRECTED and IMPROVED.

By A SOCIETY of GENTLEMEN,

Members of the SOCIETY for the Encouragement of ARTS, MANUFACTURES, and COMMERCE.

LONDON:

Printed for R. BALDWIN, HAWES, CLARKE and COLLINS, S. CROWDER, T. LONGMAN, B. LAW, T. LOWNDES, and ROBINSON and ROBERTS.

And ſold by JAMES WILLIAMS, in Skinner-Row, DUBLIN.

M DCC LXIX.

ADVERTISEMENT.

HUSBANDRY is, with great juſtice, placed at the head of human arts, as having a very great advantage over all others, both with regard to antiquity and uſefulneſs. It had its birth with the world, and has always been the genuine ſource of ſolid wealth, and real treaſures; for it will furniſh a people with every thing neceſſary to render life happy and deſirable, form the principal revenues of the ſtate, and even ſupply the defect of all others, when they happen to fail.

It is therefore no wonder that the wiſeſt princes, and the moſt able miniſters, among the ancients, made it their principal ſtudy to encourage and improve the Art of Huſbandry: they well knew that the ſtrength of a ſtate ſhould not be eſtimated by the extent of its territories, but by the number of its inhabitants, and the utility of their labours. And it ſhould be remembered, that ſome of the moſt noble conſuls and dictators among the ancient Romans were taken from the Plough, and that the ſenators of that flouriſhing people ſpent the greater part of their time in the country, where they tilled their fields with their own hands. "In thoſe happy times, ſays Pliny, the earth, pleaſed at ſeeing herſelf cultivated by the hands of triumphant victors, ſeemed to make ſtronger efforts, and to produce her fruits in greater abundance." Doubtleſs becauſe they applied themſelves to the taſk with greater attention, and took the wiſeſt precautions, to render their labours ſucceſsful: for when men of genius and abilities apply themſelves to any art, they ſoon make very great improvements, and advance it to a much higher degree of perfection: while the common people, by ſervilely confining themſelves to the common mode of practice, ſeldom make any farther progreſs in their profeſſion.

But when deſtructive luxury was introduced among the old Romans, Huſbandry declined, and has never ſince reached the honourable ſtation it before poſſeſſed: owing, in a great meaſure, to an opinion founded on falſehood, namely, that the Practice of Huſbandry requires neither ſtudy, reflection, nor precepts; and is therefore beneath the notice of men of fortune and genius. The ancients, however, thought very differently: they were perſuaded, that, in order to cultivate Lands to advantage, it was neceſſary to ſtudy the works of thoſe who had written on this ſubject, and to add the experience of others to their own. This opinion is now once more happily eſtabliſhed; and the Study of Huſbandry purſued with ſuch aſſiduity in different parts of Europe, that an amazing number of the moſt important diſcoveries have been lately made in that uſeful and neceſſary branch of knowledge.

But

ADVERTISEMENT.

But theſe uſeful Diſcoveries and Improvements are ſcattered through a multitude of volumes, written in different languages, and publiſhed in different countries; ſo that they can only be known to thoſe who have abilities to purchaſe, and leiſure ſufficient to peruſe ſo great a variety of books.

The authors of this undertaking were therefore perſuaded, that a Work, containing the Precepts relating to the Theory and Practice of every Branch of Huſbandry, delivered in the plaineſt and moſt intelligent manner, and enriched with all the Diſcoveries hitherto made in any part of Europe, would greatly tend to promote the Intereſt of their country. Filled with this pleaſing Idea, they chearfully undertook the laborious taſk; and have accordingly collected in this Dictionary all the valuable Precepts, Obſervations, Diſcoveries, and Improvements, contained in the writings of *Linnæus*, *Barck*, *Tarello*, *Duhamel*, *Chateauvieux*, *De Liſle*, the Marquis of *Turbilly*, *Fitz-Herbert*, *Hartlib*, *Platt*, *Evelyn*, *Houghton*, *Worlidge*, *Stillingfleet*, *Mortimer*, *Tull*, *Ellis*, *Miller*, *Hale*, *Liſle*, *Roque*, *Mills*, and ſeveral other Authors; together with thoſe publiſhed by the Societies of *Berne*, *Lions*, *Tours*, *Paris*, *Rouen*, *Edinburgh*, *London*.

And they hope it will be remembered, that this is the Firſt Attempt to give a COMPLETE SYSTEM of every branch of Huſbandry, and to blend in One Work the various Diſcoveries made in different nations. They alſo hope that the pains they have taken to inſert every thing belonging to the ſame ſubject in one article, and to range the whole in alphabetical order, will be approved of by the Public, as it evidently tends to facilitate the Study of Huſbandry, by enabling the Reader to find, with the greateſt eaſe and expedition, whatever ſubject he may be deſirous of conſidering.

The great number of large COPPER-PLATES, with which this Dictionary is illuſtrated, muſt alſo prove a very valuable addition, and render it far ſuperior to any Treatiſe of this kind ever yet offered to the World; as it is impoſſible to convey an adequate idea of the various inſtruments, lately invented or improved for facilitating the practice of Huſbandry, without the aſſiſtance of large and accurate drawings. This has, however, rendered the work far more expenſive; but being determined to make it as complete as poſſible, they have ſpared nothing in their power to ſucceed; and the great ſucceſs the Work has already met with has demonſtrated, that they have not exerted themſelves in vain.

THE

THE COMPLETE FARMER:

OR, A

GENERAL DICTIONARY

OF

HUSBANDRY.

ABELE-TREE, a ſpecies of poplar, growing naturally in all the temperate parts of Europe, and called by botaniſts *populus foliis lobatis dentatis ſubus tomentoſis.*

The leaves of the abele-tree are large, and divided into three, four, or five lobes, which are indented on their edges, of a very dark colour on their upper ſide, but very white and downy on their under, ſtanding upon foot-ſtalks about an inch long. The young branches have a purple bark, and are covered with a white down; but the bark of the ſtem and older branch is grey. In the beginning of April, the male flowers or catkins appear, which are cylindrical, ſcaly, and about three inches long; about a week after come out the female flowers, or catkins, which have no ſtamina like thoſe of the male. Soon after theſe come out, the male catkins fall off, and in five or ſix weeks after, the female flowers will have ripe ſeeds incloſed in a hairy covering; then the catkins will drop, and the ſeeds will be wafted by the winds a great diſtance. This tree is often confounded with the white poplar; but they are in reality diſtinct ſpecies.

The abele-tree may be propagated either by layers or cuttings, which will readily take root, or by ſuckers, which they ſend up from their roots in great plenty. The beſt time for tranſplanting theſe ſuckers is in October, when their leaves begin to decay. Theſe may be placed in a nurſery for two or three years to get ſtrength before they are planted out where they are deſigned to remain; but if they are propagated from cuttings, it is better to defer the work till February, at which time truncheons of two or three feet long ſhould be thruſt about a foot and a half into the ground. Theſe will readily take root, and if the ſoil, in which they are planted, be moiſt, will arrive to a conſiderable bulk in a few years.

A conſiderable advantage may be made by planting theſe trees upon boggy ſoils, where few other trees will thrive. Many ſuch places there are in England, which do not at preſent bring in much money to their owners; whereas, if they were planted with theſe trees, they would, in a very few years, be of more value than the ground, clear of all expences; but there are many perſons, who think nothing, except corn, worth cultivating in England; or, if they plant timber, it muſt be oak, aſh, or elm; and if their land be not proper for either of theſe, it is conſidered as of little value; whereas, if the nature of the ſoil was examined, and proper ſorts of plants adapted to it, there might be very great advantages made of ſeveral large tracts of land, which at this time lie neglected.

The wood of the abele-tree is very good for floors, where it will laſt many years, and for its exceeding whiteneſs is, by many perſons, preferred to oak; but,

being of a ſoft nature, is very ſubject to take the impreſſions of nails, &c. which renders it leſs proper for this purpoſe. It is alſo very good for wainſcoting rooms, being leſs ſubject to ſwell or ſhrink than moſt other woods; but for turnery-ware there is no wood equal to this for its exceeding whiteneſs, ſo that trays, bowls, and many other utenſils are made of it; the bellows-makers alſo prefer it for their uſe, as do alſo the ſhoe-makers for heels of ſhoes; it is likewiſe very good to make light carts, and the poles are very proper to ſupport hops, vines, &c. and the lopping will afford good fuel, which in many countries is much wanted. *Miller's Dict.*

The abele-tree is very proper for planting where you deſire a ſpeedy ſhelter and walks, it often making ſhoots of eighteen or twenty feet long in a year. *Mortimer's Huſbandry.*

ABLAQUEATION, the removing the earth, and laying bare the roots of fruit trees in winter, that they may be the more readily expoſed to the influence of rains, ſnow, air, &c. an operation formerly thought neceſſary for their future welfare; but experience has ſhewn it to be a dangerous practice, eſpecially where the trees are much expoſed to the winds, particularly the ſouth-weſt, which are generally the moſt violent. The practice of ablaqueation is therefore with very good reaſon laid aſide in the preſent practice.

ABORTIVE CORN, a diſtemper of corn mentioned by Mr. Tillet, in a Diſſertation which gained the prize at the academy of Bourdeaux.

This diſtemper, ſays that ingenious naturaliſt, ſhews itſelf long before harveſt, when the ſtalk is not above eighteen inches high; and may be known by a deformity of the ſtalk, the leaves, the ear, and even the grain.

The ſtem of abortive corn is generally ſhorter than that of other plants of the ſame age; it is crooked, knotted, and rickety; the leaves are commonly of a bluiſh green colour, curled up in various forms; ſometimes turned like wafer cakes, and often rolled in a ſpiral form. The ears have very little of their natural form; they are lean, withered, and ſhew very imperfect rudiments, either of the chaff or grain.

All theſe ſymptoms are however only to be found in plants that are in the height of the diſtemper. The ſtalks are often pretty ſtrait, the leaves but little curled, and the chaff toterably well formed; but inſtead of encloſing a ſmall embryo, white and ſoft at the ſummit, it contains only a green kernel, terminating in a point, not unlike a young pea when forming in its pod.

Theſe abortive kernels have two or three points very viſible; they are then faſhioned as if two or three kernels were joined together at the baſe. When theſe kernels are ripe, or rather when they are dried up, they grow black, and ſo greatly reſemble the ſeeds of cockle, that huſbandmen, who are not acquainted with this diſtemper, often confound abortive wheat with the ſeeds of that weed.

This diſtemper M. Tillet ſuſpects to be occaſioned by inſects; for he perceived on the ſickly plants ſmall drops of a very limpid liquor, which he judged to be extravaſated ſap.

ACORNS, the fruit of the oak, and too well known to need any deſcription. *See* OAK.

Acorns are ſaid to have been the primitive food of mankind; but at preſent they are principally uſed in fattening hogs, for which they are very proper.

Some care is, however, neceſſary to be taken when hogs feed upon acorns, for otherwiſe they will be ſubject to a diſtemper called the garget. To prevent which, the beſt way is to moiſten ſome peaſe or beans with water, and ſprinkle over it ſome antimony pounded and ſifted; if this be repeated every other day for a fortnight or three weeks, it will effectually preſerve them from the diſorder. Or if the acorns be collected and prepared in the following manner, they may be given to hogs without any danger.

Dig a hole in the ground in a warm place, large enough to contain ſeveral buſhels of acorns; in this let the acorns be put, and well moiſtened with water, in which a handful or two of common ſalt has been diſſolved: in a few days they will begin to heat and ſpire; obſerve them therefore attentively, and when they have made a ſhoot about three inches long, take them out of the hole, and ſpread them to dry on a barn floor, and in a day or two they will be fit to be given to the hogs. This matter muſt, however, be managed with care and caution; they muſt not have too many given at a time; at firſt twice a day is often enough to feed them for a day or two; afterwards three times a day. Nor ſhould they, while they eat this food, be confined to a ſtye, but ſuffered to run at large; for if their liberty be too much abridged, they will never thrive well, or grow fat on acorns.

It is no uncommon thing in Hertfordſhire, with the management above directed, and the aſſiſtance of a little waſh, and a few grains now and then, for a farmer to kill ſeveral hogs in a ſeaſon, which ſhall weigh from eight to ten ſcore, and ſometimes even more.

Theſe hogs make very good meat, but it is not ſo fine as when the hogs are taken up, and four or five buſhels of peaſe or barley meal given to each, to complete their fattening before they are killed. *Muſeum Ruſticum, vol. I. p. 475.*

ACRE, a ſuperficial meaſure of land, containing, according to the ſtatute, one hundred and ſixty ſquare poles or perches, of ſixteen feet and a half long.

But this meaſure does not prevail in all parts of England; for though one hundred and ſixty ſquare poles or perches, are allowed to be an acre, yet the length of the pole varies in different counties, and is generally called cuſtomary meaſure.

Thus the cuſtomary perch in Staffordſhire is twenty-four feet. In the foreſt of Sherwood twenty-one. In Herefordſhire the perch of walling is ſixteen feet and a half; but a perch for digging twenty-one feet.

Old farmers alſo eſtimate the acre of land by the proportion of ſeed uſed in ſowing it; by which means it muſt vary in proportion to the fertility or barrenneſs of the ſoil; and hence in many counties of England they have two ſorts of acres, diſtinguiſhed by ſeed-acres and ſtatute-acres.

The French acre, or arpent, according to Mr. Greaves's calculation, conſiſts of 100 perches of twenty-two feet each, amounting to 48,400 ſquare French feet, which are equal to 51,691 ſquare Engliſh feet, or very near one acre, and three quarters of a rood, Engliſh meaſure.

The Iriſh acre is to the Engliſh, as 196 to 121. For the number of poles in each are the ſame; but the Iriſh pole

pole is twenty-one feet, whereas the Engliſh contains only ſixteen feet and a half; and the Welch acre is equal to two Engliſh ſtatute acres.

ACREME, a quantity of land conſiſting of ten acres.

ADDERS-TONGUE, a weed growing in low moiſt meadows, where it is commonly hid among the graſs.

From a very low ſtalk ariſes a ſingle, thick, ſmooth, oblong leaf, from the bottom of which iſſues a kind of tongue, ending in a point, and indented on each ſide like a file.

ADZE, a kind of crooked axe uſed by carpenters, ſhipwrights, coopers, &c.

AFTERMATH, the ſecond crop, or graſs which ſprings up after mowing, or the graſs cut after the corn.

In the neighbourhood of London, the aftermath when made into hay, is of conſiderable value: but in haying this crop, ſo as to make it ſell well, great nicety is requiſite; the nature of the aftermath-graſs being more ſoft, ſpungy, and porous, than the firſt growth, and therefore more liable to be hurt by rains. *See* HAY.

AGE *of a horſe.* This is eaſily known by his mouth till he comes eight, after which the uſual marks wear out. A horſe, like many other brute animals, has his teeth divided into three ranks, viz. his fore-teeth, which are flat and ſmooth, his tuſhes and his back-teeth. His back-teeth, or jaw-teeth, are called his grinders, being thoſe by which a horſe chews and grinds his provender, and are twenty-four in number, twelve above, and twelve below: they are ſtrong double teeth with ſharp edges; but when a horſe grows old, they wear much ſmoother.

The firſt that grows are his foal teeth, which begin to appear a few months after he is foaled: they are twelve in number, ſix above, and ſix below; and are eaſily diſtinguiſhed from the teeth that come afterwards, by their ſmallneſs and whiteneſs, not unlike the fore-teeth of a man.

When the colt is about two years and a half old, he caſts the four middlemoſt of his foal teeth, viz. two above, and two below; but ſome do not caſt any of their foal teeth till they are near three years old. The new teeth are eaſily diſtinguiſhed from the foal teeth, being much ſtronger, and always twice their ſize, and are called the nippers or gatherers, being thoſe by which a horſe nips off the graſs, when he is feeding abroad in the fields, or, in the houſe, gathers his hay from the rack. When a horſe has got theſe four teeth complete, he is reckoned three years old.

When he is about three and a half, or in the ſpring before he is four years old, he caſts out four more of his foal teeth, viz. two above, and two below, one on each ſide the nippers, or middle teeth: ſo that when you look into a horſe's mouth, and ſee the two middle teeth full grown, and none of the foal teeth, except the common teeth remaining, you may conclude he is four that year, about April or May. Some indeed are later colts, but that makes little alteration in the mouth.

The tuſhes appear near the ſame time with the four laſt mentioned teeth, ſometimes ſooner than theſe, and ſometimes not till after a horſe is full four years old: they are curved like the tuſhes of other beaſts, only in a young horſe they have a ſharp edge all round the top, and on both ſides, the inſide being ſomewhat grooved and flattiſh, inclined to a hollowneſs.

When a horſe's tuſhes do not appear for ſome time after the foal teeth are caſt out, and the new ones come in their room, it is generally owing to their foal teeth having been pulled out before their time, by the breeders or other dealers in horſes, to make a colt of three years old appear like one of four, that he may be the more ſaleable; for when any of the foal teeth have been pulled out, the others ſoon come in their places; but the tuſhes having none that go before them, can never make their appearance till their proper time, viz. when a horſe is about four, or coming four; and therefore one of the ſureſt marks to know a four year old horſe, is by his tuſhes, which are then very ſmall, and ſharp on the top and edges.

When a horſe comes five, or rather in the ſpring before he is five, the corner teeth begin to appear, and at firſt but juſt equal with the gums, being filled with fleſh in the middle. The tuſhes are alſo by this time grown to a more diſtinct ſize, though not very large: they likewiſe continue rough and ſharp on the top and edges. But the corner teeth are now moſt to be remarked; they differ from the middle teeth in being more fleſhy on the inſide, and the gums generally look rawiſh upon their firſt ſhooting out, whereas the others do not appear diſcoloured. The middle teeth arrive at their full growth in leſs than three weeks, but the corner teeth grow leiſurely, and are ſeldom much above the gums till a horſe is full five: they differ alſo from the other fore-teeth in this, that they ſomewhat reſemble a ſhell; and thence are called the ſhell teeth, becauſe they environ the fleſh in the middle half way round; and as they grow, the fleſh within diſappears, leaving a diſtinct hollowneſs and openneſs on the inſide. When a horſe is full five, theſe teeth are generally about the thickneſs of a crown piece above the gums. From five to five and a half they will grow about a quarter of an inch high, or more; and when a horſe is full ſix, they will be near half an inch, and in ſome large horſes a full half inch above the gums.

The corner teeth in the upper jaw fall out before thoſe in the under, ſo that the upper corner teeth are ſeen before thoſe below; on the contrary, the tuſhes in the under gums come out before thoſe in the upper.

When a horſe is full ſix years old, the hollowneſs on the inſide begins viſibly to fill up, and that which was at firſt fleſhy grows into a browniſh ſpot, not unlike the eye of a dried garden bean, and continues ſo till he is ſeven; with this difference only, that the tooth is more filled up, and the mark, or ſpot, becomes faint, and of a lighter colour. At eight the mark in moſt horſes is quite worn out, though ſome retain the veſtiges of it a long time; and thoſe who have not had a good deal of experience, may ſometimes be deceived by taking a horſe of nine or ten years old for one of eight. It is at this time only, when a horſe is paſt mark, that one can eaſily err in knowing the age of a horſe; for what practices are uſed to make a very young horſe or colt appear older than he is, by pulling out the foal teeth before their time, may be diſcovered by feeling along the edges where the tuſhes grow, for they may be felt in the gums before the corner teeth are put forth; whereas, if the corner teeth come in ſome months before the tuſhes riſe in the gums, we may reaſonably ſuſpect that the foal teeth have been pulled out at three years old.

It will, perhaps, be needleſs to mention the tricks that

are uſed to make a falſe mark in a horſe's mouth, by hollowing the tooth with a graver, and burning a mark with a ſmall hot iron; becauſe thoſe who are acquainted with the true marks, will eaſily diſcover the cheat by the ſize and colour of the teeth, by the roundneſs and bluntneſs of the tuſhes, by the colour of the falſe mark, which is generally blacker, and more impreſſed than the true mark, and by many other viſible tokens, which denote the advanced age of a horſe.

After the horſe has paſſed his eighth year, and ſometimes at ſeven, nothing certain can be known by the mouth. It muſt, however, be remembered, that ſome horſes have but indifferent mouths when they are young, and ſoon loſe their mark; others have their mouths good for a long time, their teeth being white, even, and regular, till they are ſixteen years old and upwards, together with many other marks of freſhneſs and vigour; but when a horſe comes to be very old, it may be diſcovered, by ſeveral indications, the conſtant attendants of age, viz. his gums wear away inſenſibly, leaving his teeth long and naked at their roots: the teeth alſo grow yellow, and ſometimes browniſh. The bars of the mouth, which in a young horſe are always fleſhy, and form ſo many diſtinct ridges, are, in an old horſe, lean, dry, and ſmooth, with little or no riſing. The eye-pits in a young horſe (except thoſe come of old ſtallions) are generally filled up with fleſh, look plump and ſmooth; whereas, in an old horſe, they are ſunk and hollow, and make him look ghaſtly, and with a melancholy aſpect. There are alſo other marks which diſcover a horſe to be very old, viz. grey horſes turn white, and many of them all over flea-bitten, except about their joints. This, however, happens ſometimes later, and ſometimes ſooner, according to the variety of colour and conſtitution. Black horſes are apt to grow grey over their eye-brows, and very often over a good part of their face, eſpecially thoſe who have a ſtar or blaze fringed round with grey when they are young. All horſes, when very old, ſink more or leſs in their backs, and ſome horſes, that are naturally long backed, grow ſo hollow with age, that it is ſcarce poſſible to fit them with a ſaddle. Of this kind are ſeveral Spaniſh and Barbary horſes, and many of the Daniſh and Flanders breed. Their joints alſo grow ſo ſtiff with old age, and their knees and hocks bend ſo, that they are apt to trip and ſtumble upon the leaſt deſcent, though the way be ſmooth, and no ways rugged. After which they can be of little uſe to the owner. *Gibſon on Horſes.*

AGE *of neat cattle*, viz. *the ox, cow, and bull.* The age of theſe animals is known by the teeth and horns. At the end of ten months they ſhed their firſt fore-teeth, which are replaced by others, larger, but not ſo white; and in three years all the inciſive teeth are renewed. Theſe teeth are at firſt equal, long, and pretty white; but as the creatures advance in years, they wear, become unequal, and black. They alſo ſhed their horns at the end of three years; and theſe alſo are replaced by other horns, which like the ſecond teeth continue. The manner of the growth of theſe horns is not uniform, nor the ſhooting of them equal. The firſt year, that is the fourth year of the creature's age, two ſmall pointed horns make their appearance, neatly formed, ſmooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a horny cylinder, which lengthening in the ſame manner, is alſo terminated by another button, and ſo on: for the horns continue growing as long as the creature lives. Theſe buttons become annular joints, which are eaſily diſtinguiſhed in the horn, and by which the age of the creature may be eaſily known; counting three years for the point of the horn, and one for each of the joints. *Buffon's Hiſtoire Naturelle, tom.* IV.

AGE *of ſheep.* Theſe animals in their ſecond year have two broad teeth; in their third year they have four broad teeth before; in their fourth year ſix broad teeth, and in their fifth year eight broad teeth. After which none can tell how old a ſheep is while their teeth remain, except by being worn down. *Ellis on Sheep.*

At the end of one year, rams, ſheep, and weathers, loſe the two fore-teeth of the lower jaw; and they are known to want the inciſive teeth in the upper jaw. At eighteen months the two teeth joining to the former, alſo fall out; and at three years, being all replaced, they are even and pretty white. But as the creature advances in age, they become looſe, blunt, and afterwards black. The age of the ram, and all horned ſheep, may alſo be known by their horns, which ſhew themſelves in their very firſt year, and often at the birth, and continue to grow a ring annually to the laſt period of the creature's life. *Buffon's Hiſtoire Naturelle, tom.* V.

AGE *of goats.* The age of goats is known by the ſame tokens as thoſe of the ſheep, viz. by their teeth, and the annular rings on their horns.

AGRICULTURE, the art of tilling, manuring, and cultivating the earth, in order to render it fertile.

This art claims the precedency of all others in point of antiquity, it having been the ſole employment of our firſt parents in the delightful garden of Eden.

Adam inſtructed his children in this neceſſary art, both by precept and example; and we are told by the ſacred hiſtorian, that Cain applied himſelf to huſbandry, while Abel led the life of a ſhepherd, and contented himſelf with feeding his flocks.

After the deluge the deſcendants of Noah carried with them the art of huſbandry, and eſtabliſhed it in the various countries where they ſettled. It was, however, very ſimple in theſe early ages, and its advances towards perfection ſlow and almoſt imperceptible.

Abraham, and the reſt of the patriarchs, who had no fixed reſidence, applied themſelves to a paſtoral life, ennobling, by their example, a profeſſion, which has now for many ages loſt its original dignity, from its being practiſed only by the meaner ſort of people. But as ſoon as their deſcendants were fixed in Paleſtine, they all became huſbandmen, from the chief of the tribe of Judah, to the loweſt branch of the family of Benjamin: birth at that time made no diſtinction, and agriculture was conſidered as a very honourable employment.

The Chaldeans, who inhabited the countries where agriculture had its birth, carried that valuable art to a conſiderable degree of perfection: they cultivated their lands with great aſſiduity, and enjoyed the pleaſing ſatisfaction of receiving from their fields a very plentiful harveſt. The Egyptians, who from the fertility of their country, cauſed by the annual overflowings of the Nile, raiſed prodigious quantities of corn, were ſo ſenſible of the bleſſings reſulting from agriculture, that they aſcribed the invention of it to Oſiris; and even carried their ſuperſtitious gratitude ſo far, as to worſhip thoſe animals that laboured in tilling the ground.

The

The Phœnicians, ſo well known in the ſacred writings by the name of Philiſtines, were alſo famous for their ſkill in agriculture; but finding themſelves too much confined in their native country by the conqueſts of the Iſraelites, they ſpread themſelves through the greater part of the iſlands of the Mediterranean, and carried with them their knowledge in huſbandry.

The Carthaginians followed the taſte of their anceſtors, and applied themſelves aſſiduouſly to the ſtudy of agriculture. Mago, their famous general, wrote no leſs than twenty-eight books on that ſubject, and which Columella tells us, were tranſlated into Latin by an expreſs decree of the Roman ſenate. Servius adds, that Virgil uſed theſe books as a model when he wrote his Georgics.

The ancients tell us, that the goddeſs Ceres was born in Sicily, where ſhe invented the art of ſowing corn, and the tillage of land. The meaning of this fable is very evident; that iſland was very fruitful in corn, and agriculture was there eſteemed ſo honourable an employment, that even their kings did not diſdain to practiſe it with their own hands.

But time, which at firſt gave birth to arts, often cauſed them alſo to be forgotten, when they were removed from the place of their origin. The children of Noah, who ſettled in Europe, doubtleſs carried with them the knowledge of agriculture; but their deſcendants, who took poſſeſſion of Greece, were ſuch a ſavage race, that they fed on herbs, after the manner of beaſts. Pelaſgus taught them the culture of the oak, and the uſe of acorns as food, for which divine honours were paid him.

The Athenians, who were the firſt that received any tincture of politeneſs, taught the uſe of corn to the reſt of the Greeks; they alſo taught them the manner of cultivating the ground, and preparing it for the ſeed. The Greeks ſoon perceived that bread was more wholeſome, and its taſte more delicate than acorns; and accordingly thanked the gods for ſuch an unexpected and beneficial preſent. After this the Athenian kings thinking it more glorious to govern a ſmall ſtate wiſely, than to aggrandize themſelves by foreign conqueſts, withdrew their ſubjects from war, and employed them ſolely in cultivating the earth. This conſtant application carried agriculture to a conſiderable degree of perfection, and ſoon reduced it into an art.

Heſiod, who is generally thought to have been cotemporary with Homer, was the firſt among the Greeks who wrote on this ſubject. He calls his poem, "Works and Days;" becauſe agriculture requires exact obſervations of times and ſeaſons.

The other eminent Greek writers upon agriculture, are Democritus of Abdera, Socraticus, Xenophon, Tarentinus, Architas, Ariſtotle, and Theophraſtus, from whom the art received conſiderable improvements; as alſo from Hieron, Epicharmus, Philometor, and Attalus.

The old Romans eſteemed agriculture ſo honourable an employment, that in the earlieſt times of the republic, the higheſt praiſe that could be given a man, was to ſay of him, that he cultivated well his own ſpot of ground. The moſt illuſtrious ſenators applied themſelves to this profeſſion; nor had they either ſplendor or majeſty, but when they appeared in public. And their greateſt generals at their return from the toils of war, from taking of cities, and ſubduing of nations, were impatient till they were again employed in cultivating their lands, and thought it no diſgrace to follow the plough, though they were at the ſame time prepared to ſerve the wants of the republic, attend her councils, or put themſelves at the head of her armies.

It muſt indeed be allowed, that when the Romans became tainted with the luxury of Aſia, they gradually loſt the noble ſimplicity of their anceſtors, and employed their ſlaves in the ſeverer labours of a country life. But though they did not themſelves hold the plough, yet even men of conſular dignity looked upon it as a reward for their public ſervices, when they obtained leave to retire into the country, and were equally reſpected when overlooking their farms, as when ſeated in the chair of magiſtracy. M. Cato, the cenſor, that illuſtrious Roman general, orator, politician, and lawyer, after having governed provinces, and ſubdued nations, did not think it below his ſtation to write a large treatiſe on agriculture.

This work, according to Servius, was dedicated to his own ſon, and was the firſt Latin treatiſe on that ſubject. This work has been handed down to us in all its purity, in the ſame manner as Cato wrote it. Varro compoſed a treatiſe on the ſame ſubject, and on a more regular plan. This work is embelliſhed with all the Greek and Latin erudition of that learned author. Agriculture alſo received great improvements from the two Saſernaes, and likewiſe from Scorſa, Tremellius and M. Terentius. Virgil has adorned it with the language of the muſes, and given it majeſty by his verſe. He has finely embelliſhed the precepts of huſbandry left by Heſiod and Mago.

Columella, who flouriſhed in the reign of the emperor Claudius, wrote twelve books on huſbandry. He was a native of Bœtica in Spain, and had devoted his time to the ſtudy of huſbandry.

From this time till the reign of Conſtantine IV. huſbandry continued in a declining ſtate, when that wiſe emperor cauſed a large collection of the moſt uſeful precepts relating to agriculture to be extracted from the beſt writers, and publiſhed under the title of Geoponics. Some ſay he made this collection with his own hand. Nor is this at all improbable, as it is well known, that after he had conquered the Saracens and Arabians, he not only practiſed, but ſtudied the arts of peace, fixing his chief attention on the advancement of huſbandry.

But from the time of Conſtantine IV. till about the year 1478, agriculture lay in a kind of dormant ſtate, when Creſcenzio publiſhed an excellent performance on agriculture at Florence. He was ſoon followed by ſeveral of his countrymen, among whom Tatti, Stefano, Aguſtino Gallo, Sanſovino, Lauro, and Tarello, deſerve particular honour.

In the mean time Fitz-Herbert, judge of the Common Pleas, ſhone with unrivalled luſtre in the practical parts of huſbandry. He publiſhed two treatiſes on this ſubject; the firſt, which was entitled, The Book of Huſbandry, appeared 1534, and the ſecond, called, The Book of Surveying and Improvements, in 1539.

Fitz-Herbert's books of agriculture ſoon raiſed a ſpirit of emulation in his countrymen, and many treatiſes of the ſame kind ſucceſſively appeared; but time has deprived us of many of thoſe writings, or at leaſt they are become ſo very ſcarce, as only to be found in the libraries of the curious.

About the year 1600, France made ſome conſiderable efforts to revive huſbandry, as appears from ſeveral large works

writer, particularly *Les Moyens de devenir Riche*, and the *Cofmopolite*, by Bernard de Paliſſy, a poor potter; *Le Theatre d'Agriculture*, by de Serres; *L'Agriculture, & Maiſon Ruſtique*, by Meſſrs. Etienne and Liebault, &c.

The Flemings, about the ſame period, dealt more in the practice of huſbandry, than in publiſhing books on the ſubject; ſo that their intention doubtleſs was to carry on a private lucrative trade, without inſtructing their neighbours: and hence it happened, that whoever was deſirous of copying their method of agriculture, was obliged to travel into their country, and make his own remarks. The principal, and indeed juſt, idea of huſbandry conſiſted in this, namely, to make a farm reſemble a garden as near as poſſible. Such an excellent principle at firſt ſetting out led them of courſe to undertake the culture of ſmall eſtates only, which they kept free from weeds, continually turning the ground, and manuring it plentifully and judiciouſly.

When they had by this method brought the ſoil to a proper degree of cleanlineſs, health, and ſweetneſs, they ventured chiefly upon the culture of the more delicate graſſes, as the ſureſt means of acquiring wealth in huſbandry upon a ſmall eſtate, without the expence of keeping many draught horſes or ſervants.

A few years experience was abundantly ſufficient to convince them, that ten acres of the beſt vegetables for feeding cattle, properly cultivated, would maintain a larger ſtock of grazing animals, than forty acres of common farm graſs. They alſo found that the beſt vegetables for this purpoſe, were lucern, ſaintfoin, trefoil of moſt denominations, ſweet fenugreek, buck and cow-wheat, field turnips, and ſpurrey.

The political ſecret of their huſbandry therefore conſiſted in letting farms on improvement. They alſo diſcovered eight or ten new ſorts of manure. They were the firſt among the moderns who ploughed in living crops for the ſake of fertiliſing the earth, and confined their ſheep, at night, in large ſheds built on purpoſe, whoſe floors were covered with ſand or virgin earth, &c. which the ſhepherd carted away every morning to the compoſt dunghill.

Our fatal domeſtic wars, during the reign of Charles I. changed the inſtruments of huſbandry into martial weapons; but after the death of that unfortunate monarch, artful and avaricious men crept into the confiſcated eſtates of the nobility, gentry, and clergy; and as many of theſe new encroachers had riſen from the plough, ſo they returned with pleaſure to their old profeſſion, being chiefly animated by the love of gain. Plattes, Hartlib, Blythe, and others, ſeized this favourable diſpoſition of the common people, and encouraged it by writings which have ſince had few equals; nor was Cromwell wanting to lend his aſſiſtance.

Sir Hugh Platt was one of the moſt ingenious huſbandmen of the age in which he lived; yet ſo great was his modeſty, that all his works, except his Paradiſe of Flora, ſeem to be poſthumous. He held a correſpondence with all the lovers of agriculture and gardening in England; and ſuch was the juſtice and modeſty of his temper, that he always named the author of every diſcovery communicated to him. Perhaps no man, in any age, diſcovered, or, at leaſt, brought into uſe ſo many new ſorts of manure. Witneſs his account of the compoſt and covered dunghill, and his obſervations on the fertiliſing qualities lodged in ſalt, ſtreet-dirt, and the ſullage of ſtreets in great cities, clay, fuller's earth, mooriſh earth, dunghills made in layers, fern, hair, calcination of all vegetables, malt-duſt, willow-tree earth, ſoap-boilers aſhes, marle, and broken pilchards.

Gabril Plattes may be eſteemed an original genius in huſbandry. He began his obſervations in the time of queen Elizabeth, and continued them through the reigns of James I. Charles I. and during the firſt three or four years of the common-wealth. But notwithſtanding the great merit of this writer, the public ſuffered him to ſtarve and periſh in the ſtreets of London; nor had he a ſhirt upon his back when he died.

Samuel Hartlib, a celebrated writer on huſbandry in the laſt century, was highly beloved and eſteemed by Milton and other great men of that time. In his preface to a work commonly called his Legacy, he laments that no public director of huſbandry was eſtabliſhed in England by authority; and that we had not adopted the Flemiſh method of letting farms upon improvement. This remark of Hartlib procured him a penſion of one hundred pounds a year from Cromwell; and the writer afterwards, the better to fulfil the intention of his benefactor, procured Dr. Beati's excellent annotation on the Legacy, with other valuable pieces from his numerous correſpondents.

About the time when this author flouriſhed ſeems to have been an æra when the Engliſh huſbandry roſe to great perfection; for the preceding wars had made the country gentry poor, and, in conſequence thereof, induſtrious. They found the cultivation of their own lands to be the moſt profitable poſt they could occupy. But a few years after, when the reſtoration took place, all this induſtry and knowledge were exchanged for diſſipation and heedleſſneſs; and then huſbandry paſſed almoſt entirely into the hands of farmers.

The famous work attributed to Hartlib, and called the Legacy, was only drawn up at Hartlib's requeſt; and, after paſſing through his correction and reviſal, was publiſhed by him. The real author of this treatiſe was R. Child. It conſiſts of one general anſwer to the following queſtion, namely, "What are the actual defects and omiſſions, as alſo the poſſible improvements in Engliſh huſbandry?"

Several other pieces on huſbandry followed the publication of the Legacy, and greatly improved that neceſſary and uſeful art.

The firſt writer that inſpired his countrymen with a deſire of reviving the ſtudy of agriculture after the reſtoration was Evelyn; who, being followed by the famous Tull, opened a new ſphere for the minds of mankind to range in; and ſince this period ſeveral valuable improvements have been made in the Engliſh huſbandry, by a great variety of authors.

Ireland, about the middle of the laſt century, began to make no inconſiderable figure in the art of huſbandry. It muſt, indeed, be confeſſed that Ireland had very ſtrong prejudices in behalf of a very wretched method of agriculture, till about the middle of the laſt century, when Blythe opened the eyes of that people by his incomparable writings. Since which a certain ſpirit of improvement has, more or leſs, been promoted and carried on with great zeal and conſtancy by the nobility, clergy, and gentry of that kingdom. In proof of which it will be ſufficient to obſerve, that the tranſactions of the Dublin ſociety for encouraging huſbandry, are now

cited

cited by all foreigners in the memoirs relating to that ſubject.

After the peace of Aix-la-Chapelle, almoſt all the nations of Europe, by a ſort of tacit conſent, applied themſelves to the ſtudy of agriculture; and continued to do ſo, more or leſs, amidſt the univerſal confuſion that ſoon ſucceeded. The French found by repeated experience, that they could never maintain a long war, or procure a tolerable peace, without they raiſed corn enough to ſupport themſelves in ſuch a manner as they ſhould not be obliged to ſubmit to harſh terms on the one hand, or periſh by famine on the other. Their king therefore thought proper to give public encouragement to agriculture, and has even been preſent at the making of ſeveral experiments. The great and rich of various ranks and ſtations followed this example, and the very ladies put in for their ſhare of fame in this commendable undertaking. Even during the hurry and diſtreſſes of the laſt war, ſome attention was paid to agriculture. Prize queſtions were then propoſed annually in rural academies; particularly at the two academies of Lyons and Bourdeaux. And many alterations were made by the ſociety for improving agriculture in Britany.

Since the concluſion of the peace matters have been carried on with great vigour. The univerſity of Amiens has made various propoſals to the public for the advancement of huſbandry; while the marquis de Tourbilly, a writer who proceeds chiefly on experience, has the principal direction of a georgical ſociety lately eſtabliſhed at Tours.

The ſociety of Rouen alſo deſerves our notice: nor have the king and his miniſters thought it unworthy their notice. The archbiſhop of the dioceſe is one of the members.

We ſhall only add on this ſubject, that there are at preſent thirteen ſocieties exiſting in France, eſtabliſhed by royal approbation, for the promoting of agriculture; and theſe thirteen ſocieties have nineteen co-operating ſocieties belonging to them, whenever it happened that a diſtrict was too large to be effectually taken care of by one ſociety.

The art of agriculture is, at preſent, publickly taught both in the Swediſh, Daniſh, and German univerſities, where the profeſſors may render effectual ſervice to their reſpective countries, if they underſtand the practical as well as the ſpeculative parts, and can converſe to as much advantage with the farmer and peaſant, as with Virgil and Columella.

Nor has Italy been inactive. The Neapolitans of the preſent age have condeſcended to return back to the firſt rudiments of revived huſbandry, and begun to ſtudy afreſh the agriculture of Creſcenzio, firſt publiſhed in the year 1478. The people of Bergamo have purſued the ſame track, and given the world a new edition of the *Ricordo d'Agricultura di Tarello*, which was originally publiſhed at Mantua in 1577.

The dutchy of Tuſcany has embibed the ſame ſpirit. A private gentleman has lately left his whole fortune to endow an academy of agriculture. The firſt eccleſiaſtic in that duchy is preſident of the ſociety, and many of the chief nobility are members. Even Ferrara, a ſmall territory in the papal dominions, has contributed its juſt contingent, and made ſome laudable attempts in huſbandry.

Animated with a deſire that the people under his government ſhould excel in huſbandry, his Sardinian majeſty has ſent ſubjects to learn the practice of foreign countries, and made ſeveral attempts to eſtabliſh a better method of agriculture among his ſubjects.

In Poland, where a natural fertility of ſoil ſeems to diſpenſe with the neceſſity of calling in improvements, Mr. de Bieleuſki, grand-marſhal of the crown, has made abundance of ſucceſsful attempts to introduce the new huſbandry among his countrymen, and procured the beſt inſtruments for that purpoſe from France and other parts of Europe.

The Hollanders give little attention to agriculture, if we except one ſingle collateral inſtance, namely, the draining of fens and moraſſes; and even that has proceeded more from the motive of ſelf-preſervation, than any particular turn towards huſbandry.

In the year 1759, a ſociety eſtabliſhed itſelf at Berne in Switzerland, for the advancement of agriculture, and rural œconomics. That ſociety conſiſts of many ingenious private perſons, and alſo of ſome of great weight and influence in the republic; moſt of them men of a true caſt for the improvement of huſbandry, being enabled to join the practice with the theory. They have already publiſhed ſeveral uſeful pieces, which we ſhall be careful to inſert under their proper heads.

We muſt not omit to mention here, that Linnæus and his diſciples have performed great things in the north of Europe, particularly in diſcovering new, profitable, and well taſted food for cattle. At the ſame time Sweden has augmented a commerce that had been long cramped within narrow bounds, and beſtowed ſucceſsful labours on a ſoil, which was before looked upon as cold, barren, and incapable of melioration; of this the late memoirs publiſhed at Stockholm will be a laſting monument.

Denmark, as well as many courts in Germany, follow the like example. His Daniſh majeſty encourages, in particular, the woollen manufacture; and the late king ſent three perſons into Arabia Felix, to make remarks, and bring over ſuch plants and trees as may be uſeful in huſbandry, building, &c.

At the ſame time the duchy of Wirtemberg, a country no ways unfavourable to corn and paſturage, has not failed to contribute its aſſiſtances towards the improvement of agriculture, having ſome time ago communicated to the public its œconomical relations from the preſs at Stutgard.

Nor have the learned of Leipſic and Hanover been inattentive to this great art of ſupporting human kind, and that amidſt all the rage and devaſtations of war; witneſs the *Journal d'Agriculture*, printed at Leipſic, and the *Recueils d'Hanovre*, printed at that city.

Even Spain, naturally inactive on theſe occaſions, in ſpite of all the prejudices of a bigotted religion, has invited Linnæus, with the offer of a large penſion, to ſuperintend a college founded for the ſake of making new inquiries into the hiſtory of nature, and the art of agriculture.

But England alone exceeds all modern nations in huſbandry; and there is reaſon to hope, from the ſpirit that now animates a great number of the nobility and gentry, that this uſeful art will, in a few years, be carried to a much greater degree of perfection than it ever yet reached in any age or country. The reſpectable patriots that form the ſociety eſtabliſhed at London, for the

the encouragement of arts, ſeem determined to contribute all that lies in their power towards the advancement of agriculture. They have already done much, and there is reaſon to hope they will do more. A vaſt variety of different machines for facilitating the practice of agriculture have been ſent them in conſequence of their large premiums and bounties. Such munificence and attention to public proſperity may be truly called royal, as it would caſt a luſtre on the greateſt monarch that ever ſwayed a ſceptre. We ſhall conclude this hiſtory, with obſerving, that the reader will find under the proper articles a more minute account of the various improvements that have been lately made in the different parts of Europe.

AGRIMONY, a troubleſome pyrennial plant in paſture grounds. It has generally a ſingle, round, rough ſtalk, with leaves placed alternately upon it, which are winged with ſmaller leaves placed between the larger pairs. The yellow flowers grow alternately along the ſtalk, in a long row, after the manner of a ſpike, and are ſucceeded by rough ſeeds.

AIR, that thin dilatable, and compreſſible body in which we breathe, and which ſurrounds the earth to a great height.

The air, beſides its various other uſes, is a principal cauſe of the vegetation of plants, an inſtance of which we have from Mr. Ray, in the Philoſophical Tranſactions, of lettuce-ſeed, that was ſown in the glaſs receiver of the air-pump, which was exhauſted and cleared from all air, which grew not at all in eight days time; whereas ſome of the ſame ſeed, that was ſown at the ſame time in the open air, was riſen to the height of an inch and an half in that time; but the air being let into the exhauſted receiver, the ſeed grew up to the height of two or three inches in the ſpace of one week.

Another inſtance of the uſefulneſs of the air in vegetation, is the ſedum, which will puſh out roots without earth and water, and live for ſeveral months: and ſome ſort of aloes, if hung up in a room entirely ſecured from froſts, will remain freſh for ſome years, though they will ſenſibly loſe in their weight. Air is capable of penetrating the porous and ſpongy parts of plants, and being there contracted, of dilating itſelf again.

The air operates alſo within the bowels of the earth, and, by its ſubtilty perſpiring through the pores, aſſiſts in the rarefaction of the crudities of the earth, and in the diſpelling all ſuperfluous moiſture, entering into the very pores and veins of the trees, plants, herbs, &c. carrying along with it thoſe ſalts contained either in itſelf, or lodged in the earth: which ſalts or juices are altered according to the ſeveral figures or dimenſions of the different ſtrainers or veſſels of thoſe ſeveral plants which grow upon the ſame ſpot of earth, which is ſo impregnated with theſe ſalts: and thence thoſe varieties in taſte and ſmell proceed, notwithſtanding they all receive their nouriſhment from the ſame ſtock that is lodged in the earth.

The air alſo affects the branches, leaves, and flowers of trees, plants, and herbs, entering and perſpiring through them, and even through the bark and body of trees: and by the ſame kind of ſubtilty it does, by its refreſhing breezes, moderate the intenſeneſs of the ſunbeams, cooling, chearing, blowing, opening, and extending all the offspring of nature. The air fixes and inſinuates its æreal ſubſtance into the liquid ſap of vegetables: and, as all the agitations in nature proceed from the contrariety of parts inhabiting together, in this æreal and liquid ſubſtances, being mixed, cauſe the agitation and motion in vegetables, or, more properly, ſet it all into a ferment, whether it be in the roots, or in the ſtem; and it riſes by co-operation of the ſun, which is the third agent in vegetation, up to the top of a tree, &c. as liquids riſe by fire to the top of the containing veſſel.

The air, we find, produces a vibratory motion in ſeveral bodies; and, particularly in plants, the air-veſſels thereof perform the office of lungs: for the air contained in them ſometimes contracting, and ſometimes expanding, according as the heat is increaſed or diminiſhed, preſſes the veſſels, and eaſes them again by turns; and thus promotes a circulation of their juices, which could ſcarce be otherwiſe effected.

Air, ſays the learned Dr. Hales, is a fine elaſtic fluid, with particles of very different natures floating in it, whereby it is admirably fitted by the great author of nature, to be the breath or life of vegetables, as well as animals, without which they can no more live nor thrive than animals can. As a proof of the great quantities of air in vegetables, he refers to the third chapter of his excellent Treatiſe of Vegetable Statics, where, he ſays, in the experiments on vines, the great quantities of air was viſible, which was continually aſcending through the ſap into the tubes; which manifeſtly ſhews what plenty of it is taken in by vegetables, and is perſpired off with the ſap through the leaves.

He adds ſeveral experiments, as to an apple-branch, apricot-branch, birch, and other plants, to prove the ſame thing.

And Dr. Grew has obſerved, that the pores are ſo large in the trunks of ſome plants, as in the better ſort of thick walking-canes, that they are viſible to a good eye without a glaſs; but, with a glaſs, the cane ſeems as if ſtuck at top full of holes with great pins, ſo large as very well to reſemble the pores of the ſkin in the ends of the fingers, and ball of the hand.

In the leaves of pines, they likewiſe, through a glaſs, make a very elegant ſhew, ſtanding almoſt exactly in rank and file through the length of the leaves. Whence it may be thought probable, that the air freely enters plants, not only with the principal fund of nouriſhment by the roots, but alſo through the ſurface of their trunks and leaves, eſpecially at night, when they are changed from a perſpiring to a ſtrongly imbibing ſtate.

Dr. Hales likewiſe tells us, that, in all thoſe experiments that he tried to this purpoſe, he found that the air entered very ſlowly at the bark of young ſhoots and branches, but much more freely through old bark; and that in different kinds of trees it had different degrees of more or leſs free entrance.

And likewiſe, that there is ſome air both in an elaſtic and unelaſtic ſtate, mixed with the earth (which may well enter the roots with the nouriſhment) he found by ſeveral experiments, which he gives in the abovementioned treatiſe.

The excellent Mr. Boyle, in making many experiments on the air, among other diſcoveries, found, that a good quantity of air was produceable from vegetables, by putting grapes, plumbs, gooſeberries, peas, and ſeveral other ſorts of fruits and grain, into exhauſted and unexhauſted

unexhauſted receivers, where they continued for ſeveral days emitting great quantities of air.

This put the curious Dr. Hales upon further reſearches to find out what proportion of air he could obtain out of the vegetables in which it was lodged and incorporated; and, from a vaſt variety of curious and accurate experiments, concludes, that air abounds in vegetable ſubſtances, and bears a conſiderable part in them: and, that if all parts of matter were only endowed with a ſtrongly attracting power, all nature would then become one unactive cohering lump.

Wherefore it was abſolutely neceſſary, in order to the actuating this vaſt maſs of attracting matter, that there ſhould be every where mixed with it a due proportion of ſtrongly repelling elaſtic particles, which might enliven the whole maſs, by the inceſſant action between them and the attracting particles.

And ſince theſe elaſtic particles are continually in great abundance reduced by the power of the ſtrong attracters, from an elaſtic to a fixed ſtate, it was therefore neceſſary, that theſe particles ſhould be endued with a property of reſuming their elaſtic ſtate, whenever they were diſengaged from that maſs in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and diſſolution of vegetable, as well as animal bodies.

The air is very inſtrumental in the production and growth of vegetables, both by invigorating their ſeveral juices, while in an elaſtic active ſtate, and alſo by greatly contributing, in a fixed ſtate, to the union and firm connection of the ſeveral conſtituent parts of thoſe bodies, viz. their water, fire, ſalt, and earth.

To conclude, by reaſon of thoſe properties of the air before-mentioned, it is very ſerviceable to vegetables, in that it collects up and breaks open the clouds, thoſe treaſures of rain, which nouriſhes the vegetable tribe.

The air alſo helps to waft or diſperſe thoſe foggy humid vapours which ariſe from the ſoil, and would otherwiſe ſtagnate, and poiſon the whole face of the earth.

The air, by the aſſiſtance of the ſun, aſſumes and ſublimates thoſe vapours into the upper regions; and theſe foggy humid vapours are, by this ſublimation, and the coercive power of the air and ſun, rarefied, and made again uſeful in vegetation.

On the contrary, the air, which in ſo many ways is ſubſervient to vegetables, is alſo, upon ſome accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts above, but alſo to the roots and fibres below the earth: for as the air penetrates deep into the ſoil, it is natural to conclude, that a dry, huſky, ſcorching air, may be very prejudicial to the tender fibres of new planted vegetables.

ALDER-TREE, the name of a tree very common in moſt parts of England. It hath male and female flowers, which are produced at remote diſtances on the ſame plant; the male flowers are digeſted into a long juli or catkin, which is looſe, imbricated, and cylindrical. The female flowers are collected into a conical ſcaly head, and are ſucceeded by ſcaly cones.

Theſe trees delight in a moiſt ſoil, where few other trees will thrive, and are a great improvement to ſuch lands; they are propagated either by layers, or planting of truncheons about three feet in length. The beſt time for this is in February, or the beginning of March; theſe ſhould be ſharpened at one end, and the ground looſened with an inſtrument before they are thruſt into it; leſt, by the ſtiffneſs of the ſoil, the bark ſhould be torn off, which may occaſion their miſcarriage. Theſe truncheons ſhould be thruſt into the earth two feet at leaſt, to prevent their being blown out of the ground by ſtrong winds, after they have made ſtout ſhoots. The plantations ſhould be cleared from all ſuch weeds as grow tall, otherwiſe they will overbear the young ſhoots; but when they have made good heads, they will keep down the weeds, and will require no farther care.

If you raiſe them by laying down the branches, it muſt be performed in October; and by the October following, they will have taken root ſufficient to be tranſplanted out; which muſt be done by digging a hole, and looſening the earth in the place where each plant is to ſtand, planting the young trees at leaſt a foot and a half deep, cutting off the top to about nine inches above the ſurface, which will occaſion them to ſhoot out many branches.

The diſtance theſe trees ſhould be placed, if deſigned for a coppice, it ſix feet ſquare; and if the ſmall lateral ſhoots are taken off in the ſpring, it will very much ſtrengthen your upright poles, provided you leave a few ſmall ſhoots at diſtances upon the body thereof, to detain the top for the increaſe of its bulk.

Theſe trees may be alſo planted by the ſide of brooks, as is uſual for willows, where they will thrive exceedingly, and may be cut for poles every fifth or ſixth year. This wood is in great requeſt with the turners, and will endure a long time under ground, or to be laid in water. *Miller's Gard. Dict.*

Alder makes an extraordinary fence againſt rivers and ſtreams, and preſerves the banks from being undermined by the water; becauſe it is always ſending ſuckers from the loweſt roots, which makes it very uſeful, where ſtreams wear away the banks, and are widening of their courſe. *Mortimer's Huſbandry.*

Alder has one peculiar and beneficial property, namely, that no beaſt will crop it, be it young or old, which ſaves the great charge of fencing it after planting. *Ellis's Timber Tree improved.*

ALE, a fermented liquor obtained from the infuſion of malt, and differing only from beer in having a leſs proportion of malt and hops. *See the articles* BEER *and* BREWING.

GILL-ALE, is ale in which the dried leaves of gill, or ground-ivy, have been infuſed. It is eſteemed good in diſorders of the breaſt, and obſtructions of the viſcerae.

ALLEY, in the new huſbandry, implies the vacant ſpace between the outermoſt row of corn on one bed, and the neareſt row to it on the next parallel bed. *See* BED.

The practice of the new huſbandry has already ſufficiently ſhewn, that too narrow alleys would hardly anſwer any of the ends for which they are intended; and, on the other hand, the making them too wide is a loſs of ground. About four feet, excluſive of the ſpaces or partitions between the rows of corn in the beds, is a good middling breath.

It is not indeed neceſſary to make the alleys quite ſo wide in good ſoils; an intelligent huſbandman will eaſily judge what breadth is moſt proper. But what greatly merits the attention of every one, and ought never to

be loſt ſight of, is, that wide alleys are more eaſily and much better ſtirred than thoſe which are narrower: for when an alley is wide, the large furrow in the middle of it may be cut deep, there being then ſufficient room to turn the earth over towards the rows; while, on the other hand, the earth, in two narrow alleys, cannot be ſtirred deep enough, nor can room be found for what is turned over out of the furrows, without danger of burying great part of the rows.

We will, therefore, ſuppoſe the general breadth of the alleys to be about four feet; but the whole of that breadth is not to be ploughed or ſtirred, either with the plough or cultivator, as ſoon as the field is ſown. Neither of theſe inſtruments ought to go too near the rows of corn, for fear of rooting up the plants; but a ſlip of earth about ſix inches wide, ſhould be left untouched on the outſide of each bed; by which means the part of the alley that is to be ſtirred, will be reduced to the breadth of three feet; and even that is leſſened in the firſt ploughing before winter by a deep furrow, which is then cut cloſe to, and all along thoſe ſix inch ſlips, and the earth taken out of each furrow, is thrown into the great furrow in the middle of the alley, which it ſerves to fill and arch up. Theſe two ſide furrows make together a breadth of about eighteen inches, and, conſequently leave, in the middle of the alley, a breadth of about eighteen inches more, on which is heaped up the earth thrown out of the two furrows: and thus the alleys remain all the winter.

The firſt hoeing in the ſpring ſhould turn the earth, heaped up in the middle of the alleys, back towards the rows of corn. The two furrows that were opened before winter are then filled up, and a new one is cut in the middle of the alley.

To perform the firſt hoeing with the common plough, which may be very eaſily done, two turns of that inſtrument will be requiſite, namely, one on each ſide of the alley, as near as poſſible to the beds. But as theſe two turns will not be always ſufficient to form the furrow perfectly, a great deal of earth frequently remaining between it and the bed, a third turn of the plough becomes often neceſſary; and ſometimes a fourth, to hollow the middle furrow as it ought to be.

If this work be performed with the cultivator with two mould-boards, the inſtrument muſt be placed in the middle of the alley, and the horſes in one of the two furrows. The ſhare will eaſily enter a great depth into the earth, which was laid there by the laſt hoeing before winter: and as the horſes advance, that great ridge of earth will be divided into two parts, which will be turned over into, and fill up the furrows that were made before winter, on each ſide of the alley, cloſe to the beds. *See the article* CULTIVATOR.

Thus the great furrow in the middle of the alley will be opened, and the whole operation performed by one turn of the cultivator. The earth thus turned over will be thoroughly ſtirred, and ſo much time and labour will be ſaved by this method, that the farmer may eaſily afford one or two ſtirrings more in the ſummer, which will always be of great ſervice. *M. de Chateauvieux.*

ALLEY, in gardening, implies a ſtrait walk, bounded on both ſides with trees or ſhrubs, and commonly covered with gravel or graſs.

An ally is diſtinguiſhed from a path, by being broad enough for two perſons to walk a-breaſt, whereas a path is ſuppoſed to admit of only one at a time; but if an alley be wider than ten or twelve feet, it may, with more propriety, be called a walk.

Covered ALLEY, is that where the trees on each ſide meet at the top, ſo as to form a ſhade.

ALMOND-TREE, is generally cultivated in gardens for the beauty of its flowers. Theſe often appear in February, when the ſpring is forward; but if froſt comes on after the flowers appear, their beauty will be of ſhort duration, and in thoſe ſeaſons few almonds are produced; whereas when the trees do not flower till late in March, they ſeldom fail to bear plenty of fruit; many of which will be very ſweet, and fit for the table when green, but they will not keep long.

Almond-trees are propagated by inoculating a bud of theſe trees into a plum, almond, or peach ſtock, in the month of July. The next ſpring, when the buds ſhoot, you may train them up, either for ſtandards, or ſuffer them to grow for half ſtandards, according to your own fancy.

The beſt ſeaſon for tranſplanting theſe trees, if for dry ground, is in October, as ſoon as the leaves begin to decay; but for a wet ſoil, February is much preferable: obſerve always to bud upon plum-ſtocks for wet grounds, and on almond or peach-ſtocks for dry. *Miller's Gard. Dict.*

ALP, a name in many counties of England for the bulfinch.

AMEL-CORN, the ſame with Spelt. *See* SPELT.

AMBERVALIA, a ceremony practiſed by the ancient Romans, in order to procure from the gods a happy harveſt.

This ceremony conſiſted of a proceſſion in which the victims were conducted thrice round the corn fields before they were ſacrificed. Twelve prieſts walked at the head of the proceſſion, which conſiſted of all the neighbouring inhabitants, every one being crowned with leaves of oak, and ſinging hymns in honour of Ceres, the goddeſs of corn.

AMBLE, a peculiar kind of pace, wherein a horſe's two legs of the ſame ſide move at the ſame time.

In this pace the horſe's legs move nearer the ground than in the walk, and, at the ſame time, are more extended: but what is moſt ſingular in it is, that the two legs of the ſame ſide, for inſtance, the off hind and fore-leg, move at the ſame time; and then the two near legs, in making another ſtep, move at once; the motion being performed in this alternate manner. So that the two ſides are alternately without ſupport, or any equilibrium between the one and the other, which muſt neceſſarily prove very fatiguing to the horſe, being obliged to ſupport himſelf in a forced oſcillation, by the rapidity of a motion, in which his feet are ſcarcely off the ground. For if in the amble he lifted his feet as in the trot, or even in a walk, the oſcillation would be ſuch, that he could not avoid falling on his ſide, and it is only by keeping his feet very near the ground, and by the quick alternate motion that he ſupports himſelf in this pace, in which the hind leg is not only to move at the ſame time with the fore-leg of the ſame ſide, but alſo to gain on it, or touch the ground a foot, or a foot and a half, beyond the ſpot where the latter grounded. The further the hind-leg extends beyond the place where the fore-leg grounded, the better the horſe ambles, and the whole motion is proportionally faſter. Thus the whole difference between the amble and

and the trot conſiſts in this, that the two legs moving together in the latter are in a diagonal poſition, whereas, in the former, the two legs of the ſame ſide move together.

This pace, which is very fatiguing to the horſe, is very eaſy to the rider. It has not the roughneſs of the trot, which is cauſed by the reſiſtance of the fore-leg, at the liſting up of the hind; becauſe, in the amble, this fore leg is lifted up at the ſame time with the hind-leg of the ſame ſide; whereas in the trot the fore-leg of the ſame ſide is at reſt, and reſiſts the impulſe during the whole time that the hind leg is in motion.

They who are ſkilled in horſemanſhip tell us, that horſes which naturally amble, never trot, and that they are a great deal weaker than others. Colts, indeed, very often move in this manner, eſpecially when they exert themſelves, and are not ſtrong enough to trot or gallop. Moſt good horſes, which have been overworked, and on the decline, are alſo obſerved voluntarily to amble, when forced to a motion ſwifter than a walk.

The amble may, therefore, be conſidered as a defective pace, not being common, and natural only to a very few horſes, which, in general, are weaker than others. Add to this, that ſuch amblers as ſeem the ſtrongeſt, are ſpoiled ſooner than thoſe which trot or gallop. *Buffon's Hiſtoire Naturel, tom.* IV.

There are various methods of diſcipline for bringing a young horſe to amble: ſome chuſe to toil him in his foot pace through new ploughed fields, which naturally inures him to the ſtroke required in the amble; but this diſorderly toil is very apt to weaken, and ſometimes to lame a young horſe. Others attempt it by ſtopping him in a gallop, or trot; ſo that by loſing both, he neceſſarily ſtumbles on an amble; but this is apt to ſpoil a good mouth and rein, and expoſes the horſe to the danger of an hoof-reach, or ſinew-ſtrain, by over-reaching, &c. Some preſer ambling by weights as the beſt way; and in order to this, either overload the horſe with exceſſive heavy ſhoes, or fold thick peices of lead about the ſetlock paſterns, without conſidering that the former are apt to make him interfere, or ſtrike ſhort with his hind-feet; and that the latter, beſides that miſchief, expoſe the horſe to incurable ſtrains, cruſhing of the coronet, breeding of ring-bones, &c. Others load the horſe with earth, lead, &c. which often occaſion a ſwaying of the back, over-ſtraining of the fillets, &c. Some endeavour to make him amble in hand, before they mount his back, by means of ſome wall, ſmooth pale, or rail, and by checking him in the mouth with the bridle-hand, and correcting him with a rod on the hinder hoofs, and under the belly, when he treads falſe; but this is very apt to ſpoil a ſpirited horſe, even before he can underſtand what you would have him do.

The beſt method ſeems to conſiſt in trying with your hands, by a gentle and deliberate racking and thruſting of the horſe forwards, by helping him in the weak part of his month with your ſnaffle, which muſt be ſmooth, big, and full; and correcting him firſt on one ſide, then on the other, with the calves of your legs, and ſometimes with a ſpur. If you can by this means make him fall readily into an amble, though in a ſhuffling and diſorderly manner, much labour will be ſaved; for that aptneſs to amble will render the tramel more eaſy to him, and he will find the motion without ſtumbling, or being frighted. *See the article* TRAMEL. *Bradley's Dict. Ruſt.*

AMBRY, ACEMBRY, or AUMERY, a pantry or cupboard to ſet victuals in.

ANBURY, a kind of wen, or ſpongy wart growing on any part of a horſe's body. *See the article* WEN.

ANGORA *goat*. *See the article* GOAT.

ANJOU *cabbage-ſhrub*, an exellent vegetable both for the kitchen, and the food of cattle, cultivated with great ſucceſs in ſeveral provinces of France; and that ingenious huſbandman, the marquis of Turbilly, lately ſent a parcel of the ſeeds to our ſociety for the encouragement of arts, who very readily diſtributed them to ſuch gentlemen as applied to them for that purpoſe, in order to their being cultivated here; ſo that there is reaſon to hope, that this uſeful plant will ſoon become common in England. The following inſtructions are given by the marquis de Turbilly, for cultivating the Anjou cabbage.

"The great Anjou cabbage is one of the moſt uſeful leguminous plants for country people. It will grow in almoſt any ſoil, not excepting even the moſt indifferent, provided it be ſufficiently dunged. It is but little known about Paris, and in many other places, where it might be cultivated to great advantage.

"The ſeeds of this cabbage are commonly ſown in June, in a quarter of good mould, in the kitchen garden, and watered from time to time in caſe of drought. The plants will riſe pretty ſpeedily, and ſhould be thinned ſoon after, wherever they ſtand too thick. The next care is to keep them free from weeds whilſt they continue, by hoeing the ground between them. About the firſt of November, they ſhould be tranſplanted into the field where they are to remain. They ſhould be planted there in trenches dug with a ſpade, pretty deep, that is, they ſhould be buried almoſt up to the leaves. The diſtance between them ſhould be two feet, or two feet and a half every way, according to the goodneſs of the ſoil. Particular care ſhould be taken never to plant them with a dibble, as gardeners plant other ſorts of cabbages. A layer of dung ſhould be ſpread along the bottom of the trench, and the roots of the tranſplanted cabbages covered therewith. The mould taken out ſhould then be returned back upon the dung; and as the trench will then no longer hold it all, there will remain a ridge between each row of cabbages.

"Towards the middle of May enſuing, the ground ſhould be well ſtirred between the plants, with a ſpade, or ſome other proper inſtrument, and its whole ſurface laid quite level. After this nothing more remains to be done, except pulling up the weeds, from time to time, as they appear.

"Many huſbandmen ſow the ſeeds of theſe cabbages with thoſe of hemp; and though this may not be ſo ſure as the former, it often ſucceeds very well, eſpecially in wet years. When the hemp is pulled up, a multitude of little cabbages are ſeen, and which having then a free air, grow apace. They are tranſplanted about the firſt of November in the manner before directed, and are preferred to thoſe of the kitchen garden, becauſe they are not ſo apt to run up to ſeed the next ſpring; an accident which ſometimes happens to a few of theſe cabbages, in certain years; and it then becomes neceſſary to replace them by others which have not run up, and which are reſerved for this purpoſe in a ſeparate ſpot of ground.

"Several farmers uſe a plough to cut the trench for

tranſplanting theſe cabbages; but then they do not remove them till the ſpring, leaving them, in the mean time, in the place where they were ſown. They afterwards give the earth a ſtirring with the ſpade, and lay it ſmooth towards the end of May, in the manner before directed. Whole fields of theſe cabbages may be ſeen on many farms in Anjou and Poitou, and which prove a very uſeful reſource.

"In the month of June, ſuch of theſe cabbages as are already large, and do not turn in their leaves for cabbaging, but ſtill continue green, begin to be fit for uſe, and ſoon ariſe at their full perfection, which they retain till the next ſpring, when they begin to run up, and afterwards bloſſom. Their ſeeds ripen towards the end of July, and what is intended for ſowing ſhould then be gathered.

"In Anjou, when theſe cabbages are entirely run up, they generally grow to the hight of ſeven or eight feet: ſometimes they reach to eight feet and a half, or nine feet; nay, ſome have even been ſeen of a greater height.

"From the month of June, when theſe cabbages begin to be fit for uſe, their leaves are gathered from time to time, and they ſhoot out again. They are large, excellent food, and ſo tender that they are dreſſed with a moment's boiling. They never occaſion any flatulencies or uneaſineſs in the ſtomach; and are alſo very good food for cattle, which eat them greedily. They likewiſe greatly increaſe the milk of cows.

"Such are the properties of this kind of cabbage, greatly eſteemed in Anjou, Poitou, Britany, Le Maine, and ſome other neighbouring provinces. In Anjou farmers are bound by their leaſes to plant yearly a certain number of theſe cabbages, and to leave a certain number of them ſtanding when they quit their farms.

"This cabbage forms a kind of ſhrub, the great utility of which may be gathered from this, that its leaves afford nouriſhment to men and cattle; and its ſtalk, which is about the thickneſs of one's wriſt, is uſed, when dry, for fuel.

"It ſometimes happens in extremely ſevere winters, that ſome of theſe cabbages are frozen; and this, in the above provinces, is conſidered as a very great loſs; but that accident is rare, becauſe this kind of cabbage reſiſts froſts better than moſt others.

"The ground where theſe cabbages are planted ſhould be fenced in very carefully by hedges or ditches, to preſerve it from the depredations of cattle, which are extremely fond of them. With this precaution I have made ſeveral plantations of them, near the houſes erected in the midſt of the heaths and commons I have broken up and improved; and they have ſucceeded very well, though the ſoil is but indifferent in many places.

"I have, near my houſe in Anjou, two well incloſed fields, deſtined for this ſort of plantation. They are planted alternately every year with young cabbages. When theſe are pulled up, after they have ſeeded in the ſecond year, at the time already mentioned, the ground where they ſtood is dug up, and ſowed with peaſe or beans, the crop of which being taken off before the firſt of November, makes room for planting new cabbages at the proper ſeaſon. The ſoil is looſened and enriched by the peaſe and beans, and by this means the land is never reſted; nor is it ever exhauſted, becauſe it is dunged whenever the cabbages are planted.

"Theſe cabbages are of ſuch excellent ſervice to me, that I have often wondered at their not being cultivated in all the different countries of Europe. I believe they would ſucceed every where, and I adviſe all huſbandmen to make plantations of them.

"I wiſh that this ſhort memoir, founded on my own experience, may contribute to extend the culture of this uſeful plant."

ANNUAL *plants*, ſuch as continue one year only; or ſuch as ſpring up, ripen their ſeed, and periſh in that ſpace of time. Thus wheat, barley, oats, beans, peaſe, &c. are annual plants.

ANNUAL *meadow-graſs*, called in ſome parts of England, Suffolk-graſs, a ſpecies of very beautiful graſs, making the fineſt turfs, and ſeems particularly well adapted to dairy farms. *See* Plate I. Fig. 1. *which repreſents this graſs in its perfection.*

"I have, ſays Mr. Stillingfleet, ſeen whole fields of it in High Suffolk, without any mixture of other graſſes; and as ſome of the beſt ſalt butter we have in London comes from that country, it is moſt likely to be the beſt graſs for the dairy." He adds, that he obſerved, upon Malvern-hill, a walk made there for the convenience of the water drinkers, which was, in many places, covered over with this graſs, in leſs than a year, though he could not find a ſingle plant of it beſides in any other part of the hill. This was doubtleſs owing to the frequent treading, which has the greateſt tendency to make this graſs flouriſh; and therefore it is very evident, that rolling muſt be very ſerviceable to it. As the flowers and ſtems of this plant do not grow brown ſo ſoon as thoſe of other graſſes, nor cover the radical leaves ſo much, becauſe they are conſiderably ſhorter, this affords a more pleaſing turf than any other graſs." *Stillingfleet's Miſcel. Tracts.*

Mr. Ray obſerves of the common meadow graſs, that it is a ſlender and ſucculent plant, very agreeable to cattle, and a fattener of them; that it delights in a rich ſoil; and that it is not injured by being trodden under foot, and therefore is commonly found along the ſides of paths and roads. It ſpindles and ears in the ſpring, and continues to ſhoot during the whole ſummer. *Ray's Hiſtory of Plants.*

As plenty of the ſeeds of this graſs might be very eaſily procured from Suffolk, it might be propagated and cultivated in all parts of England, where the ſoil and ſituation are adapted to its growth.

It is indeed amazing, that amidſt the great variety of graſſes which grow naturally in England, that ſo few farmers have had any thoughts about improving their meadows and paſtures; they ſeem to take every thing upon truſt, imagining, perhaps, that the graſs they find growing naturally in their grounds, is much better, and more adapted to the nature of the ſoil, than any other they could ſow, or adopt in its ſtead.

But this is ſurely a very narrow way of thinking, and ſhould it be encouraged, would ſoon put a ſtop to all improvements in huſbandry. We have been too long influenced by cuſtom: it is time for us to ſhake off our fetters, and rouze ourſelves from the deep lethargy which has prevented us from receiving, or at leaſt from removing the diſadvantages of the old huſbandry, which, in many reſpects, is highly diſadvantageous both to the farmer and his country.

ANTICOR, a diſeaſe among horſes, conſiſting of a malignant ſwelling in the breaſt; which extends ſometimes to the very ſheath under the belly; and is attended with

J. Hibbert Sculp.

with a fever, great depreſſion and weakneſs, and a total want of appetite.

The cure ſhould be firſt attempted by large and repeated bleedings, to abate the inflammation; emollient clyſters ſhould be injected twice or thrice a day, with an ounce of ſal prunella in each. The ſwelling ſhould be bathed with marſhmallow ointment, and an opening poultice, with onions boiled in it, ſhould be daily applied over it. If by this method continued four or five days, the inflammation in the throat and gullet be removed, the attention ſhould more particularly turn to encourage the ſwelling on the breaſt, and bring it, if poſſible, to matter: let the poultice therefore be continued, and give the horſe two ounces of Venice treacle, diſſolved in a pint of beer, every night. When the ſwelling is grown ſoft, it muſt be opened with a knife, and dreſſed with turpentine digeſtive, the danger being then over.

But ſhould it be found impracticable to bring the ſwelling to matter, and the ſwelling upwards ſhould increaſe ſo as to endanger ſuffocation, authors have adviſed to pierce the humour with a hot pointed cautery, and dreſs part with the turpentine digeſtive, ſharpened with a ſmall quantity of Spaniſh flies and uphorbium in powder, in order to ſtimulate and promote a greater diſcharge; at the ſame time fomenting and bathing the adjacent parts with ointment of marſhmallows.

M. Gueriniere, as well as Soleyſel, have adviſed opening the ſkin, when the tumour cannot be brought to matter, in order to introduce a piece of black hellebore-root ſteeped in vinegar, and to confine it there for twenty-four hours; this alſo is intended as a ſtimulent, and is ſaid to anſwer the intention, by occaſioning ſometimes a ſwelling as big as a man's head. *Bartlet's Farriery.*

ANTS, or *piſmires*, are injurious both to paſture lands and gardens; in the former by throwing up hills, and in the latter, by feeding on the fruit, &c.

The method of keeping them from trees is by encompaſſing the ſtem with a circle or roll of wool, newly plucked from the ſheep's belly, four fingers in breadth, or by laying ſaw-duſt round the tree. The ſame will be effected when you anoint the tree with tar; but as tar is prejudicial to trees, human ordure will, perhaps, do better; becauſe if any of it be put into their hills, it will kill them. *Mortimer's Huſbandry.*.

ANT-*hills*, the habitations of the ants, conſiſting of little eminences, compoſed of ſmall particles of ſand, lightly and artfully laid together.

Theſe hills, or habitations of the ants, though very convenient for themſelves and their own ſocieties, are very deſtructive to the farmer, depriving him of as much land as theſe hills cover; which may be often computed at a tenth part, or more, of his valuable graſs lands. Nay, in ſome places, where negligence has ſuffered them to multiply, almoſt half of it has been rendered uſeleſs: the hills ſtanding as thick together as graſs-cocks in hay time: and what is moſt ſurprizing, this indolence is defended by affirming, that the area or ſuperficies of their land is thereby encreaſed: whereas it is well known, by the induſtrious, that very little or no graſs ever grows thereon; and, therefore, if the ſurface be increaſed, the produce is proportionably decreaſed. *See the article* MOLE-HILL.

It has been a cuſtom in many places at the beginning of winter, and often when the weather was not very cold, to dig up the ant-hills, three or four inches below the ſurface of the ground; and then to cut them in pieces, and ſcatter the fragments about: but this only diſſeminates the inſects inſtead of deſtroying them; they can hide themſelves among the roots of the graſs for the preſent; and then collect themſelves together again upon any little eminence, of which there are great numbers ready for their purpoſe, viz. the circular ridges round the hollows, where the hills ſtood, as is very ſoon viſible to a curious obſerver. A much better method ſeems therefore to be pointed out by a writer in the *Muſeum Ruſticum*, vol. vi. namely, to cut off the hills entire, and even with the ſurface; and to let them lie whole at a little diſtance, with their bottom upwards: by this means the ants, which are known to be very tenacious of their neſts, will continue in their habitations, while the rains, by running into their holes of communication, aſſiſted afterwards by the froſts, which will now ſooner penetrate to their dwellings, will deſtroy them. Perhaps a little ſoot ſown on the places, and waſhed in with the rains, would have a better effect. The hills when rendered mellow by the froſts, may be broken and diſperſed about the land. This method of cutting the hills even with the ſurface, has one advantage; it leaves the paſture-land even and fit for mowing; and at the ſame time the little eminences being taken away, the inſects are expoſed to the wet, which is diſagreeable to them.

In wet weather theſe inſects accumulate cavernous heaps of ſandy particles among the graſs, called by the labourers ſprout-hills; which quickly take off the edge of a ſcythe. Theſe hills, which are very light and compreſſible, the above writer aſſures us from experience, may be readily ſtamped down, by the feet of the hay-makers, and the inſects, together with their eggs and earth, eaſily pounded to a mortar. This ſhould be repeated a ſecond, and perhaps a third time, after the itinerant foragers have returned from their queſt of food, and have begun to raiſe new ſtructures near the old demoliſhed habitations.

APHERNOUSLI, or *arkenouſli*, a ſpecies of pine, or pinaſter, growing wild on the Alps, where one would think it impoſſible that any tree could vegetate and proſper; and therefore would probably thrive to great advantage on our bleak, barren, rocky, mountainous tracts of land. See Plate I. Fig. 2.

The timber is large, and has many uſes, eſpecially within-doors, or under cover. The branches reſemble theſe of the pitch-trees, commonly called the ſpruce fir: but the cones are more round in the middle, being of a purpliſh colour, ſhaded with black. The bark of the trunk, or bole of the tree, is not reddiſh like the bark of the pine, but of a whitiſh caſt, like that of the fir. The huſk, or ſort of ſhell, which incloſes the kernels, is eaſily cracked, and the kernels are covered with a brown ſkin, which peels off; they are about as large as a common pea, triangular like buck-wheat, and white and ſoft as a blanched almond, of an oily agreeable taſte, but leaving in the mouth that ſmall degree of aſperity, which is peculiar to wild fruits, and is not unpleaſing. Theſe kernels make a part ſometimes in a Swiſs deſert; they ſupply the place of muſhroom-buttons in ragouts; and are alſo recommended in conſumptive caſes, on account of their balſamic oil.

Wainſcoting, flooring, and other joiner's work, made with the planks of aphernouſli, are of a finer grain, and more beautifully variegated than deal, and the ſmell of the

the wood is more agreeable. From this tree is extracted a white odoriferous reſin.

The aphernouſli is of a healthy, vigorous nature, and will bear removing when it is young, even in dry warm weather. The wood makes excellent firing in ſtoves, ovens, and kilns; but is dangerous to be uſed on the hearth or in grates, being apt to ſplinter and fly to a conſiderable diſtance.

This tree is the *pinus cembra* of Matthioli and Linnæus, the *pinus foliis quinis* in Haller, *the larix ſemper-virens* in the German Ephemeris, the *libanus carpathius* of ſome writers, and the *pina cinque feüeilles*, N° 20. in Du Hamel. It grows in great abundance on the moſt mountainous and coldeſt parts of the Briançonnois, where it is called by the natives *alviez*. It bears ſome reſemblance to the white Canada pine, which is better known in England by the name of Weymouth-pine. *Eſſays on Huſbandry.*

APIARY, a bee-garden, or place where bees are kept. See the article BEES.

APOPLEXY, or, as the farriers generally call it, the *ſtaggers*, a diſeaſe to which the horſe is ſubject, and by which the creature drops down ſuddenly without ſenſe or motion, except a working of his flanks, proceeding from the motion of the heart and lungs, which never ceaſes while any ſpark of life remains.

The previous ſymptoms are drowſineſs, watry moiſt eyes, ſomewhat full and inflamed, a diſpoſition to reel, feebleneſs, a bad appetite, and almoſt continual hanging of the head, or reſting it in his manger, ſometimes with little or no fever, and ſcarce any alteration in the dung or urine. When the apoplexy proceeds from water collected in the ſinuſes and ventricles of the brain, the horſe has generally, beſides all the foregoing ſymptoms, a diſpoſition to rear up, and is apt to fall back, when any one goes to handle him about his head. The reaſon of his falling backwards ſeems to be obvious, becauſe when the head is raiſed with his mouth upwards, the water in the ventricles cauſes a weight upon the cerebellum, or part lying under the brain, and origin of the nerves, ſo as to deprive the creature of ſenſe and motion at once: this does not, however, prove ſuddenly mortal. Young horſes are moſt ſubject to it, and, with proper helps, and good uſage, ſometimes get over it: but when the apoplexy proceeds from wounds or blows on the head, or from any other cauſe producing ruptures in the blood-veſſels, or from matter collected in the brain, or its membranes; or if any part of the brain or its membranes be indurated, or grown callous, by long continuance, the horſe will not only have moſt of the ſymptoms already deſcribed, but will be frantic by fits, eſpecially after his feeds, ſo as to ſtart and fly into motion at every thing that comes near him. Theſe caſes are extremely dangerous, and ſeldom admit of a perfect recovery. But when horſes fall down ſuddenly and work violently at their flanks, without any ability to riſe, even after plentiful bleeding, ſuch horſes ſeldom recover.

All that can be done in ſuch caſes is to ſtrike the veins in ſeveral parts at once, to raiſe up the horſe's head and ſhoulders, propping them with plenty of ſtraw; and if he ſurvive the fit, to cut ſeveral rowels; though in caſe of ruptured veſſels, or if any kind of extraneous matter be lodged on the brain, or its membranes, all theſe helps will be of little ſervice.

But if the apoplectic fit happens to be only the effect of a plethora, or fulneſs of blood, from high feeding, and want of ſufficient exerciſe; or if it be the effect of a fizy blood, which is often the caſe of many young horſes, that have been fed for ſale, or from catching cold while the blood is in this ſtate, the cure will not be attended with any great difficulty, notwithſtanding a horſe, in theſe circumſtances, may reel and ſtagger, and ſometimes fall down ſuddenly.

Firſt of all bleed plentifully, and keep the horſe for ſome time to an opening diet of ſcalded bran, and ſometimes ſcalded barley, leſſening the quantity of his hay. After two days repeat the bleeding, but in a ſmaller degree. If the horſe has a cold, it will be proper to give him pectoral drinks, proper for that diſorder. See COLD.

But if no ſymptom of a cold appear it will be neceſſary, after bleeding and a ſpare diet, to give him two or three purges, not only to remove the plethora or fulneſs but to attenuate and thin his blood, for which the following is recommended.

"Take of the fineſt ſuccotrine aloes, an ounce and a quarter; freſh jallop, two drams; ſalt of tartar, three drams; native cinnabar, or the cinnabar of antimony half an ounce; make it into a ball with a ſufficient quantity of ſyrup of roſes or marſhmallows; adding twenty or thirty drops of chemical oil of anniſeeds, making the whole into a ball, rolling it in liquorice-powder."

The purge may be made ſtronger or weaker by increaſing or diminiſhing the jallap. Let this be repeated two or three times, and the horſe will probably recover, without a relapſe. Powder of antimony, or its preparations, as the liver, the *crocus metallorum*, its cinnabar, or the native cinnabar, mixed with equal parts of gum guaiacum, may be alſo given in ounce doſes, for three or four weeks, to mend his blood, and take off its fizineſs. Nor ſhould exerciſe, as ſoon as the horſe is able to bear it, be omitted.

When a horſe drops down ſuddenly with hard riding, or violent driving, it in many reſpects reſembles an apoplexy, and all the organs of the head are affected as in an apoplexy; but as this proceeds only from the extraordinary rarefaction of the blood, and its rapid motion, whereby the ſmall veſſels of the brain, heart, and lungs, are ſo extremely diſtended as to cauſe an univerſal preſſure on the origin of the nerves; the horſe by this means loſes all ſenſe and motion, and generally falls ſuddenly, eſpecially upon any ſudden ſtop; becauſe when the bodily motion ceaſes, the circulation of the blood in the veins is not accelerated in proportion to its influx from the arteries, which ſoon produces a ſuffocation and a falling down, without ſenſe or motion. Inſtances of this kind are not uncommon, eſpecially in very hot weather, when the external heats adds greatly to the blood's motion and rarefaction. But as we ſuppoſe in this caſe, little or no fault in the blood, except, perhaps, a plethora, or weakneſs of the veſſels, the quickeſt and readieſt remedy is bleeding; and unleſs the horſe dies with the violence of the fall, which ſometimes happens, or by burſting the ſmall veſſels of the brain or lungs, or happens through polipuſes in the heart or principal veins, he will ſoon riſe of himſelf, or without much help, and may be preſerved from ſuch accidents for the future, by better uſage. *Gibſon on the Diſeaſes of Horſes.*

APPETITE, a certain painful or uneaſy ſenſation, always accompanied with a deſire to eat or drink.

Horſes, more than moſt other creatures, are ſubject to diſeaſes of the ſtomach, particularly to *a want of appetite*, and a *vitiated*, or *voracious appetite*.

Want

Want of APPETITE is when a horſe feeds poorly, and is apt to mangle his hay, or leave it in the rack, and the ſame time gathers little fleſh, and his dung habitually ſoft, and of a pale colour.

Theſe are evident ſigns of a relaxed conſtitution, wherein the weakneſs of the ſtomach and guts may have a very great ſhare. This habitual weakneſs may be either natural and hereditary, or may be cauſed by ſome previous ill management; ſuch as too much ſcalded bran, or too much hot meat of any kind, which relaxes the tone of the ſtomach or guts, and in the end produces a weak digeſtion, and conſequently a loſs of appetite.

The beſt method to harden and recover ſuch horſes, is to give them much gentle exerciſe in the open air, eſpecially in dry weather; never to load their ſtomachs with large feeds, and to keep them as much as poſſible to a dry diet, indulging them now and then with a handful of beans among their oats; but in caſe the horſe grows weak, and requires the help of phyſic, a few laxative purges like the following, ſhould be given.

"Take ſuccotrine aloes, ſix drams; rhubarb in fine powder, two drams; ſaffron dried and powdered, one dram: make it into a ſtiff ball, with a ſufficient quantity of ſyrup of roſes, and add two drams of the elixir proprietatis, prepared with oil of ſulphur by the bell."

This purge will work very gently, and bring the horſe to a better appetite, and ſtrengthen his digeſtion. It may be repeated once a week, or once in ten days, and after the operation of each purge.

"Take a large handful of the raſpings or ſhavings of guaiacum, pomegranate bark, and balauſtines bruiſed, of each an ounce; galangals and liquorice root ſliced, of each half an ounce: let theſe be boiled in ſix quarts of ſmith's forge-water, to three pints; and while it is warm, infuſe in the decoction two drams of ſaffron, and half an ounce of diaſcordium."

Let this be divided into two drinks, and give one after the purge has done working, and the other after two day's intermiſſion; in cold weather the drinks ſhould be warmed before they are adminiſtered: the ſame may be complied with after the laſt purge, and repeated as often as may be neceſſary, continuing to give the horſe conſtant exerciſe in the open free air; and this will be the likelieſt method to ſtrengthen ſuch horſes, as are of weak relaxed conſtitutions.

But where ſuch a habit is contracted by too much feeding, eſpecially on hot ſcalded diet, which is often the caſe of young horſes kept up for ſale, the beſt way is to bleed and purge ſuch horſes, and at the ſame time to rowel them in the belly; for this ſort of feeding eaſily occaſions horſes to be lax, that have no natural diſpoſition to it; for when they grow ſuddenly fat by ſuch management, the ſecretions from the guts become greaſy, which always cauſes weakneſs and relaxation in them, and often forms a proper nidus for the breeding of vermin; all which may be eaſily remedied by purging in the firſt place, and afterwards by proper exerciſe, and a clean diet.

As for thoſe horſes that are of a hot fiery diſpoſition, and loſe their appetites by their heat and fretting, it is a caſe that cannot eaſily be remedied, becauſe of the natural inflammatory diſpoſition of their blood; the only method is to keep them to a cool diet while they are young, and, in country places, to let them run abroad, eſpecially where they have ſtables and warm ranges, to keep them from the inclemency of the weather in winter; for theſe ſort of horſes are always tender, being, for the moſt part, extremely thin ſkinned, and their blood of a thin texture, and eaſily put in motion. For the ſame reaſon, the beſt way, in ſummer, is to bring them up in the day time, and only let them run abroad in the night, they being more hunted with the flies than any other, which keeps them continually upon the fret, and hinders them from thriving. When ſuch horſes live till they are full aged, their heat and fierineſs often abates, ſo that they grow more uſeful; but while they are young, they are more ſubject to inward impoſtumations than horſes of a cooler temperament; and theſe often kill them ſuddenly, or bring them into lingering conſumptive maladies, which in ſome meaſure may be prevented by the above method. *Gibſon on the Diſeaſes of Horſes.*

Vitiated, or *Voracious* APPETITE, is that where the animal is always craving for meat. *See* FOUL-FEEDING.

APRIL, the fourth month of the civil year, conſiſting of thirty days.

This month is the beſt month, if the weather be dry, to ſow barley and white oats, to deſtroy weeds, and alſo to fallow land.

Fell the timber you intend to bark, if the ſpring be forward: cleanſe and rid your coppices, and preſerve them from cattle: keep geeſe and ſwine out of commons and paſtures, and water new planted trees, if the weather prove dry.

Pick up ſtones on the new ſown land: ſow hemp and flax.

Cleanſe ditches, and get in your manure that lies in the ſtreets or lanes, or lay it in heaps.

Set oſiers, willows, and other aquatics, before they are too forward, and alſo ſlips of roſemary or lavender.

You may throughout this month ſow clover graſs, ſaintfoin, and all French and other graſſes, or hays: plant madder, and be ſelling your winter fed cattle. *Mortimer's Huſbandry.*

AQUATICS, or *aquatic* plants, ſuch plants and trees as grow in water.

Thus, the willow, oſier, water-creſſes, brook-limes, &c. are aquatics.

ARABLE *land*, ſuch land as is tilled, or cultivated for the production of corn.

ARAIRE, the name of a ſmall plough uſed in Provence and Languedoc, in France.

It conſiſts of a ground wriſt, *a*, *b*, (Plate I. Fig. 3.) from three to four feet long, ending in a point towards *b*. The under part of this wriſt, inſtead of being flat, is formed into a ridge, which extends the whole length of it.

This ground wriſt, at the end *a*, terminates in a ſtrong tenon fixed in a large mortiſe, formed at the extremity *d* of the beam *d e*, and is beſides faſtened to the beam by two iron uprights *f g*, which have a head at *g*, and going through the beam are keyed at *f*: the diſtance between the under part of the beam about *f*, and the upper part of the ground wriſt towards *g*, is about fifteen inches. Inſtead of theſe uprights there is ſometimes put a piece of ſharpened wood or iron, as repreſented by the pricked line *b g*, which ſerves inſtead of a coulter.

On the upper part of the ground wriſt is fixed a large iron ſhare *d b* (Fig. 4). the part *d i*, is received into the ſame mortiſe of the extremity *d* (Fig. 3.) in which the tenon

tenon of the ground wriſt is faſtened; and the wings of the ſhare *k l* (Fig. 4.) reſt upon the iron uprights *f g* (Fig. 3.)

On the hindermoſt part of this plough is a ſingle lever *m d* (Fig. 3.) which ſerves for a handle: at the end *d*, where it is bent, it enters, as well as the ground wriſt and ſhare, into the great mortiſe *d*, at the end of the beam; and the whole is ſecured with wedges. The handle ſometimes conſiſts of two pieces lapped one over the other, as at *n*, to lengthen or ſhorten it, according to the height of the ploughman.

By means of the wedges juſt mentioned, the angle which the ground wriſt forms with the beam, may be altered at pleaſure, which makes it plough more or leſs deep. At the hinder parts of the ground wriſts are two earth boards, faſtened at *o*, by a ſtrong wooden pin, which paſſes through both the boards and the ground wriſt.

The beam *d*, *f*, *e*, which is from eight to ten feet long, has an iron bolt at the end *e*, which enters with great eaſe into a large mortiſe made at the extremity *g*, of the piece of wood *q 5 r*, intended to paſs between the oxen, and to which their harneſs is to be faſtened. When a ſingle horſe is uſed in the plough, a ſhaft is ſubſtituted inſtead of the piece of wood *q 5 r*, and faſtened to the end of the beam *e*, by an iron ringlet.

It is evident that this plough goes a greater or leſs depth, according as the draught is more or leſs raiſed. The ploughman, as has been already obſerved, can alter the angle which the ground wriſt forms with the beam, by means of the wedges he drives into the mortiſe of the beam, which receives both the ground wriſt and handle. But theſe directions not being ſufficiently exact, it is neceſſary that the ploughman ſhould lean on the handle *m*, when it cuts too deep, and raiſe it when it makes too ſhallow a furrow: this labour is ſo conſtant, that were the plough to work in a ſtrong ſoil, the ploughman could not ſupport it. The two little earth boards *p p*, turn over to the right and left the earth that has been looſened by the ſhare; but this is not done ſo regularly, as when there is but one earth board, which throws the earth into the furrows before made, as faſt as it comes out of that which the plough is forming: it is however certain, that the ground wriſt being ridged, the ploughman always reſts it on one ſide, which occaſions the greater part of the earth to be thrown one way.

Theſe ploughs having no coulters, the earth is not cut vertically at all: for neither the piece of ſharpened wood, nor the ſheath which joins the ground wriſt to the beam, and which is placed a little before the ſmall iron bars *f*, *g*, can be eſteemed a coulter. The bar repreſented by the pricked line *h g*, may ſerve inſtead of a coulter, but it muſt then be made of iron; and in this caſe the coulter would be very improperly ſituated, for it ſhould by rights be before the ſhare.

Theſe ploughs are very convenient to uſe among trees, or in vineyards; they may alſo ſerve to ſtir the ground in the intervals between the rows of ſaint foin and lucerne; but then ſhould be rather called cultivators, than ploughs. *Du Hamel's Elements d' Agriculture.*

ARCHIMEDES's *ſcrew*, a kind of ſpiral pump, for raiſing water, ſo called from Archimedes, its inventor.

It conſiſts of a long cylinder, with a hollow pipe, tube, or groove coiled round it, as repreſented on Plate I. Fig. 5. where A B ſhews the cylinder, and C D the tube open at each end. It is placed in an oblique poſition to the horizon, with the lower end in the water to be raiſed, and the other ſupported by the pivot below the winch J K, by which the tube and cylinder are turned round.

As ſoon as the ſcrew is immerſed in the water, it immediately riſes therein by the orifice C, to the level of the ſurface of the water E F; and if the point of the ſpiral tube, which in the beginning of the motion is coincident with the ſurface of the water, happens not to be on the lower ſide of the cylinder, he water will, upon the motion of the ſcrew, move on the ſpiral tube, till it comes to the point which is on the other ſide, and coincident with the ſurface of the water; when it is arrived at that point, as ſuppoſe at O, it cannot afterwards poſſeſs any part of the ſpiral, but that which is upon the loweſt part of the cylinder; for it cannot move from O towards H or G, becauſe they are ſituated higher above the horizon; and ſince this will conſtantly be the caſe, after the water in the ſpiral has obtained the point O, it is plain that it muſt always be on the under part of the cylinder.

But becauſe the cylinder is in motion, every part of the ſpiral ſcrew from O to D, will, by degrees, ſucceed to every part thereof from O to D, as it comes on the lower ſide; that is, it muſt aſcend on the lower part of the cylinder through all the length of the pipe, till it comes to the orifice at D, where it will run out, as having nothing farther to ſupport it.

This engine may be very uſeful in raiſing water, foul with ſand, &c. as the leathers of pumps will be ſoon deſtroyed by theſe particles. And it was principally this reaſon that induced the ingenious Mr. Smeaton to erect a machine of this kind in the gardens of her royal highneſs the princeſs dowager of Wales at Kew, where it is worked by horſes, and ſupplies all the ponds, &c. in that extenſive garden with water. A machine of this kind, turned by a wind-mill, might be of great uſe in draining lands in ſeveral parts of England, as it is not ſubject to be out of order, and might be made to raiſe a very large quantity of water to a ſmall height. We ſhall deſcribe ſeveral other contrivances for this purpoſe when we come to treat of draining of lands, there being many very curious and uſeful engines of this kind depoſited in the machine room of the ſociety for the encouragement of arts, &c. *See the article* DRAINING *of* LANDS.

ARDERS, fallowings, or plowings of land.

ARK, a large cheſt to put corn or fruit in, like the bin of a buttery.

ARLES, or EARLES, earneſt; thus an arles-penny, ſignifies an earneſt penny.

AROMATIC, an epithet applied to ſuch plants, and other bodies, as yield a fine fragrant ſmell, and have a warm ſpicy taſte.

ARPENT, the French name for an acre. *See* ACRE.

We have already obſerved under the article *acre*, that the French arpent contains 100 perches of twenty-two French ſquare feet, which is equal to about one acre and three quarters of a rood Engliſh meaſure. But it may be neceſſary to add here, that the French have three different arpents, diſtinguiſhed by the epithets *little*, *middle*, and *great* arpent.

The little ARPENT contains 100 perches of eighteen feet and a half ſquare; conſequently its ſuperficial meaſure is 32,400 French feet, equal to 34,603 feet, or three rood

rood, ſeven perches, and twenty-ſeven feet Engliſh meaſure.

The middle ARPENT, conſiſts alſo of 100 perches, twenty feet ſquare, which make 40,000 French feet ſuperficial meaſure; equal to 42,720 feet, or three rood, thirty-ſix perches, and 149 feet Engliſh meaſure.

The great ARPENT, contains ten perches of twenty-two ſquare perches. *See the article* ACRE.

ARTIFICIAL GRASSES, ſuch as are introduced into the field with great care, and cultivated afterwards with much diligence. Such as burnet, clover, lucern, ſainfoin, ray-graſs, ſpurry, &c. *See the method of cultivating each under its proper article.*

ARTIFICIAL PASTURE, ſuch lands as are properly cultivated and ſown with the above plants, or any other that yield a great deal of fodder for cattle.

ASCARIDES, ſmall worms common in horſes, reſembling needles, ſome of them white, and ſome of an azure colour, with flattiſh heads. They are often called needle-worms by the farriers.

Theſe worms are very troubleſome, and hard to be rooted out, and expoſe horſes to frequent gripes, and other fretting uneaſy diſorders in their guts. They breed at all times of the year, and often when one brood is deſtroyed another ſucceeds. They are not mortal; but when a horſe is peſtered with this ſort of vermin, though he will go through his buſineſs tolerably well, and ſometimes feed heartily, yet he always looks lean and jaded; his hair ſtares as if he was ſurfeited, and nothing he eats makes him thrive; he often ſtrikes his hind-feet againſt his belly, which ſhews where his grievance lies, and is ſometimes griped, but without the violent ſymptoms that attend a cholic, or ſtrangury, for he never rolls or tumbles, but only ſhews uneaſineſs, and generally lays himſelf down quietly on his belly for a little while, and then gets up and falls a feeding; but the ſureſt ſign is when he voids them with his dung.

Theſe ſmall worms ſometimes come away in great numbers with a purge, and ſome horſes get clear of them by purges only; but this does not often happen; for the horſes that breed aſcarides are, above all others, ſubject to ſlime and wormy matter. They ſeem to have their lodgment about the beginning of the ſmall guts, near the ſtomach, among the concocted aliment or chyle, both from their colour, the ſymptoms of the gripes, and the ſudden fits of ſickneſs theſe horſes are often ſeized with, which ſometimes make them abruptly leave off their food, for a few minutes, and fall greedily to it again as ſoon as the ſick fit is over. They are ſeldom ſeen, except when a horſe has had a purge given, or when he falls into a natural purging, which thoſe horſes are often ſubject to, and then they come away in very great numbers, with much ſlime and naſtineſs. They not only make a horſe grow lean, and look ſurfeited; but in opening his mouth, one may perceive a more than ordinary languid whiteneſs, and a ſickly ſmell, from the want of thoſe due ſupplies of blood and nouriſhment, which give a livelineſs to the colour that is always perceivable in ſound vigorous horſes; ſo that whatever be the primary cauſe, theſe worms ſeem, in a great meaſure, to proceed from a vitiated appetite, and a weak digeſtion, which renders them the more difficult to be removed; for which reaſon recourſe muſt be firſt had to mercurials, and after theſe, to ſuch things as are proper to ſtrengthen the ſtomach, promote digeſtion, and give a better tone to the ſolids.

To a horſe, therefore, that is troubled with theſe ſmall white, or azure coloured worms, the following method may be obſerved:

"Take of calomel that has been often ſublimed and well prepared, two drams; diapente half an ounce; make it into a ball, with a ſufficient quantity of conſerve of wormwood, or of rue, and give it in the morning, keeping the horſe from meat and water four hours before, and four hours after taking it."

The next morning adminiſter the following purge, taking great care to keep the horſe from wet, or from any thing that may expoſe him to catch cold.

"Take Barbadoes, or plantation alloes, one ounce; ſalt of tartar, two drams; freſh ginger grated, a dram and a half; oil of amber a middling ſpoonful: make the whole into a ball with flour or liquorice powder."

This purge may be worked off in the ſtable with warm water, which is much the ſafeſt way when mercurials are given. The calomel ball and purge may be repeated in ſix or eight days; and again in ſix or eight days more.

When a horſe has gone through a courſe of theſe mercurial purges, let the following drink be given two or three times a week, and continued till the horſe begins to thrive and look healthful.

"Take rue, camomile flowers, and horehound, of each a handful; galangals, bruiſed in a mortar, three drams; liquorice root, ſliced, two drams: boil it in a quart or three pints of forge-water five or ſix minutes, in a covered veſſel, and keep it covered till cold: then ſtrain it through a piece of coarſe canvas, and give it in the morning upon an empty ſtomach." *Gibſon on the Diſeaſes of Horſes.*

ASH, or ASH-TREE. There are ſeveral ſpecies of the aſh-tree cultivated by curious perſons for the ſake of variety; but what deſerves attention in a work of this kind, is the common aſh, called by botaniſts, *fraxinus foliolis ſerratis, floribus apetalis*; and is ſo well known as to need no deſcription.

This tree propagates itſelf in plenty by the ſeeds which ſcatter in the autumn; ſo that when the ſeeds happen to fall in places where cattle do not come, there will be plenty of plants come up in the ſpring; but when any perſon is deſirous of raiſing a quantity of the trees, the ſeeds ſhould be ſown as ſoon as they are ripe, and then the plants will come up in the following ſpring; but if the ſeeds are kept out of the ground till ſpring, the plants will not come up till the year after; the ground therefore ſhould be kept clean all the ſummer where they are ſown, and not diſturbed, leſt the ſeeds ſhould be turned out of the ground, or buried too deep to grow.

When the plants are come up, they muſt be kept clean from weeds during the ſummer; and, if they make good progreſs in the ſeed-bed, they will be fit to tranſplant by the following autumn; ſome ground ſhould, therefore, be prepared to receive them; and as ſoon as their leaves begin to fall, they ſhould be tranſplanted. In taking of them up care ſhould be taken not to break or tear off their roots; to prevent which they ſhould be taken up with a ſpade, and not drawn up, as is frequently practiſed; for as many of the plants which riſe firſt from ſeeds will out-ſtrip the others in their growth,

ſo it is frequently practiſed, to draw up the largeſt plants, and leave the former to grow a year longer, before they are tranſplanted; and to avoid hurting thoſe that are left, the others are drawn out by hand, and thereby many of their roots are torn off, or broken. It is, therefore, much the better way to take all up, little or big, together, and tranſplant them out, placing the large ones together in rows, and the ſmall ones by themſelves. The rows ſhould be three feet aſunder, and the plants a foot and a half diſtance in the rows. In this nurſery they ſhould remain two years, by which time they will be ſtrong enough to plant where they are to remain, for the younger they are planted out the larger they will grow; ſo that where they are deſigned for uſe, they ſhould be planted very young; nor ſhould the ground where they are raiſed be better than that where they are deſigned to grow. For when any plants are raiſed in good land, and afterwards planted into worſe, they very rarely thrive; ſo that it is much the better method to make the nurſery upon a part of the ſame land, where the trees are deſigned to be planted, and then a ſufficient number of the trees may be left ſtanding upon the ground, and theſe will outſtrip thoſe which are removed, and grow to a larger ſize.

Where people live in the neighbourhood of aſh-trees, they may ſupply themſelves with plenty of ſelf-ſown plants, provided cattle are not ſuffered to graze on the land; for if cattle can come at them, they will eat off the young plants, and not ſuffer them to grow; but where the ſeeds fall in hedges, and are protected by buſhes, the plants will come up and thrive: in theſe hedges the trees are frequently permitted to grow till they have deſtroyed the hedge, for there is ſcarce any tree ſo hurtful to all kinds of vegetables as the aſh, which robs every plant of its nouriſhment within the reach of its roots, and ſhould therefore never be ſuffered to grow in hedge-rows; for they not only kill the hedge, but impoveriſh corn, or whatever is ſown near them. Nor ſhould any aſh-trees be permitted to grow near paſture grounds, for if any of the cows eat of the leaves or ſhoots of the aſh, all the butter that is made of their milk will be rank, and of little or no value. In all good dairy countries therefore they never ſuffer any aſh-trees to grow.

If the wood of theſe trees be rightly managed, it will turn greatly to the advantage of its owner; for by the underwood, which will be fit to cut every eight or ten years, there will be a continual income more than ſufficient to pay the rent of the ground, and all other charges; and ſtill there will be a ſtock preſerved for timber, which in a few years, will be worth forty or fifty ſhillings per acre.

This timber is of excellent uſe to the wheel-wrights and cartwrights for ploughs, axle-trees, fellies of wheels, harrows, oars, blocks for pullies, and many other purpoſes.

The beſt ſeaſon for felling theſe trees is from November to February; for if it be done either too early in the autumn, or too early in the ſpring, the timber will be ſubject to be infeſted with worms, and other inſects: but for lopping of pollards the ſpring is preferable for all ſoft wood. *Miller's Gard. Dict.*

ASHES, the earthy particles of combuſtible ſubſtances remaining after they have been burnt.

If the aſhes are produced from vegetable bodies, they contain a conſiderable quantity of fixed ſalt, blended with the earthy particles, and from theſe particles, the alcaline ſalts, called pot-aſh, pearl-aſh, &c. are extracted.

Aſhes of all ſorts contain in them a very rich fertile ſalt, and are the beſt manure of any to lay upon cold lands, eſpecially if kept dry, and the rain doth not waſh away their ſalts. One load of dry aſhes will go as far as two not kept ſo. But as rain water diminiſhes their ſalts, ſo the moiſtening them with chamber-lie, or ſoap-ſuds, will add greatly to their ſtrength. Two load of theſe aſhes will manure an acre of land better than ſix load of thoſe that are expoſed to the rain, and that are not ordered ſo, which is the common allowance for an acre, though ſome lands require more, and ſome leſs. That the aſhes of any ſort of vegetables are very advantageous to land, is what is experienced in moſt places of England, by the improvement that is made by burning of fern, ſtubble, ſtraw, heath, furze, ſedge, bean-ſtalks, &c. *Mortimer's Huſbandry.*

Coal ASHES from their calcarious quality, are ſingularly beneficial to ſtiff and ſour land, for which purpoſe they are ſucceſsfully uſed in the neighbourhood of ſome great cities, where coal is burnt for fuel. They open clayey grounds, and correct their bad qualities. The gardeners and farmers about London know their value, and make a very profitable uſe of them, particularly to bring into order thoſe grounds which have been dug for brick earth. After ſpreading theſe aſhes upon the clay bottom, they either ſow horſe-beans, or ſet the early Spaniſh, and ſometimes the Windſor-bean in thoſe ſpots; or elſe they lay ſuch lands down with rye-graſs, which generally ſucceeds very well. Mr. Bradley blaming the people of Staffordſhire, and the counties adjoining, where there are coal-pits, for not improving their heavy grounds around thoſe pits, by manuring them with coal aſhes, which might be eaſily burnt out of the waſte coals, ſays, "that wherever there are plenty of coal-pits, there can be no want of good profitable land." *Bradley's Huſbandry.*

Mr. Mortimer agrees entirely with Mr. Bradley, eſteeming ſea-coal aſhes as the beſt manure of any for cold lands, the moſt laſting, and the fitteſt to kill worms. Their ſharp and drying quality opens the pores of ſtiff ſoils, and diſcharges a great deal of their viſcous quality. Mr. Worlidge looks upon them as an excellent compoſt when mixed with horſe dung; he adds, that they are a great curer of moſs and ruſhes in moſt grounds. *Worlidge's Huſbandry.*

Kiln ASHES, made of ſtraw, furze, &c. are a good manure for almoſt any kind of ſoil. In the weſt of England farmers ſift them over their corn and graſs; but this muſt not be done in windy weather, becauſe they are ſo very light that they would be eaſily blown away. They ſucceed beſt when laid on juſt before rain or ſnow. *Mills's Huſbandry, vol.* I.

Peat ASHES are likewiſe a very good manure. Mr. Miller is of opinion, that they are greatly bettered by being mixed with lime before they are laid on the land.

Mr. Ellis has rightly obſerved, that there is a conſiderable difference between the aſhes of lean peat, and thoſe produced by the fatter kind. If barley, ſays he, be ſown ſo late as the beginning of May, lean peat aſhes in particular may be applied over it, or harrowed in with the grain; but aſhes burnt from fat black peat, ſuch as is dug at Newbury, are of ſo ſulphureous a nature,

ſure, that farmers are afraid to lay them on their barley; nor do they dreſs their wheat with them till the ſpring is advanced, and then they are ſown over it.

The earth of which this rich manure is made, is taken from a black mooriſh ground, with a narrow wood ſcoop, which brings it out like a long brick. Theſe pieces of ſwampy earth are laid on the ground to dry in the ſummer; after which they ſell for eight ſhillings a waggon load, for fuel. But when they are to be uſed for manure, after being dried, they are burnt in heaps of ten, twenty, or thirty loads, laying on more peat upon the outſides, as the fire increaſes within, to keep it from having too much vent.

The great uſe of theſe aſhes was diſcovered about fifty years ago; but they ſoon fell into diſrepute, owing to the injudicious management of people, who imprudently laid on too great quantities of them at a time, by which means the corn was burnt. Afterwards they found that ſix, or at moſt ten buſhels, were ſufficient to be ſown over an acre of wheat, peaſe, turnips, clover, rape-ſeed, or ſaintfoin, as early as could conveniently be done. But ſtill many are afraid to ſow them over barley, leſt a dry ſeaſon ſhould enſue, and burn it up: for theſe aſhes are thought to contain three times as much ſulphur as there is in coal aſhes. This is reaſonably ſuppoſed from their very ſtrong ſulphureous ſmell; their ſparkling and jumping when ſtirred while burning, and their drying up corn by their too great heat. Theſe peat aſhes, as likewiſe thoſe of wood or coal, will help to keep off the ſlug from peaſe and other grains, by the ſalt and ſulphur contained in them, and conduce very much to their preſervation in cold wet ſeaſons. But no danger of over-heating need be feared from the aſhes of that peat which grows, as turf, over ſandy bottoms, as great quantities do on Leighton heath in Bedfordſhire; for theſe are as much too lean, as the others are too rank. *Ellis's Modern Huſbandman, vol.* II.

We muſt not here omit the account the ingenious Mr. du Hamel has given of a kind of peat aſhes made in France, as the ſame kind of earth with that from whence they are burnt, may be doubtleſs found in many parts of England, if farmers would give themſelves the trouble to ſearch for it.

This peat is a blackiſh earth, reſembling the ſoil of ſome meadows. When burnt it emits a thick, diſagreeable ſulphureous vapour. A certain degree of moiſture helps to make it burn, though even then it waſtes but ſlowly. After it has once taken fire it burns of itſelf, but without producing any flame. It is of ſo cauſtic a nature, that it would ſtrip off the ſkin of the hands and feet of the men who knead it, if they did not take proper precautions againſt that inconvenience. Its aſhes retain this cauſtic quality; for the hands of thoſe peaſants who ſtrew them are often hurt by it, if the air be at all damp. This earth, in its natural poſition, runs in veins of different ſizes; ſometimes ſeven or eight feet thick, and thirty or forty feet long; and ſometimes they extend four or five hundred feet; after which the vein often fails at once, and perhaps is not found again till two or three miles off. Theſe veins generally lie pretty near the ſurface of the earth, ſeldom deeper than twelve or fifteen feet.

This earth is found only in marſhy places, which muſt ſometimes be drained before it can be come at. It ſhews itſelf by a ſlimy ſkin over the adjacent waters.

Three pounds of this earth being diſtilled in a retort, produced fifteen ounces of a bituminous oil, reſembling that extracted from pit-coal; and the reſiduum yielded, when waſhed, about half a pound of vitriol.

The method of preparing this earth, in order to render it fit for fertilizing land, is as follows: water is thrown over it, and two or three men knead it with their feet, till they bring it to the conſiſtence of a paſte, which is then made into cakes ſeven or eight inches in diameter. Theſe cakes are laid by to dry, though not to ſuch a degree but that there ſtill remains a little moiſture in them, that being neceſſary to facilitate their burning.

The cakes thus prepared are piled up in the form of a pyramid, with ſufficient ſpaces between them for the fire to penetrate; and under this pyramid, which is built upon a kind of hearth, a little ſtraw and bruſh-wood is laid to ſet them on fire. Two or three days after their aſhes are ſpread with a rake, that they may cool. Some veins of this earth yield white aſhes, but they are not ſo good as thoſe of a reddiſh hue.

From fifty to ſeventy pounds of theſe aſhes are ſpread upon each acre of land in April or May; and in about a week's time the blades of corn, or graſs, if it be paſture ground, aſſume a new verdure, and appear ſurpriſingly ſtrong, even in the coldeſt ſoils.

Some of theſe bituminous earths are better than others. Care muſt be taken to begin to rake out the aſhes of each pyramid as ſoon as the greater part of it is burnt; for they would loſe a great deal of their virtue, if left on the fire till all that is inflammable be conſumed: nor would the fire go out in leſs than a fortnight or three weeks, if they were not ſcraped away as they are formed.

It would be needleſs to mention, that a greater quantity of the aſhes of an inferior quality muſt be uſed, than thoſe that are ſtronger, and conſequently better; but it may not be amiſs to obſerve, that, in general, wet lands require more than dry ſoils. The effects of this manure will be manifeſt for two or three years. It might be dangerous to renew it every year. *Traité de la Culture de Terres, tom.* V. *pag.* 226.

Pot ASHES are the refuſe or aſhes remaining after the ſalt, called pot aſhes, is extracted from them.

Theſe aſhes are of great ſervice to moſt ſorts of land; but as they have been in a great meaſure deprived of their ſalts, it is neceſſary to lay them on much thicker than other aſhes. A buſhel and a half of theſe may be uſed for a buſhel of freſh aſhes: but they ſhould always be mixed with ſome other light ingredient, which may be uſed in any quantity, if laid on very ſtiff land. If the land be not over ſtiff, they may be laid upon it with leſs mixture. *Bradley's Huſbandry.*

Soap ASHES are a compoſition of wood aſhes and lime, remaining after the ſoap-makers have drawn off their lye.

They are an excellent manure, and were firſt uſed by the Flemings with very great ſucceſs. Two loads of theſe aſhes are ſufficient for an acre of arable land; and by the aſſiſtance of this manure the ground will not only yield a large crop, but may be ſown yearly, without leaving it fallow at any time. They ſhould be laid on the ground in the beginning of winter, that the rain may more eaſily diſſolve and waſh them in. Sir Hugh Platt tells us, that by manuring a piece of barren land at Biſhop's-hall in Middleſex, in the year 1594, he ob-

tained an excellent crop of ſummer barley; that he meaſured the ſtalk and ear of one of theſe plants, and found it to be an ell and three inches in length, from the ground to the ſummit of the ear. We have given a figure of this ear of ſummer barley in its natural ſize, on Plate III. Fig. I. *Platt's Jewel-houſe of Art and Nature.*

A writer in the *Muſeum Ruſticum* declares, that he has for many years paſt received great benefit by uſing ſoap aſhes as a manure, with which he almoſt conſtantly dreſſes his wheat lands; but never uſes it alone, on account of its hot burning quality.

"My method, adds he, is to make a large heap of dung and earth, that is two loads of earth to one of dung, placed in alternate layers to rot. After this has undergone a ſtrong fermentation, I cauſe the whole heap to be turned and well mixed, leaving it ſome time longer to mellow.

"I then procure the ſoap aſhes, and mix them with the compoſt, in the proportion of one load of aſhes to ten of the compoſt, leaving, for ſome time, the whole to mellow together.

"When wheat ſeed-time comes, about the latter end of September, I cauſe about ten cart loads of this rich compoſt to be laid in little heaps on each acre of the land I intend to ſow with wheat: this manure is immediately ſpread, and, ſowing my wheat broad caſt, I plough it in together with the compoſt.

The advantage reſulting from this practice, on ſtiff ſoils, are many; and particularly, if the farmer is the leaſt careful in preparing his tilth, he will have a clean crop, free from ſmut or weeds; a matter of no ſmall conſequence to him.

"I have tried this manure on lighter lands, and find it anſwer extremely well, provided it has lain a conſiderable time in the compoſt heap, to mellow and abate its natural heat; but it agrees beſt by far with clayey ſoils, and in ſuch is well worthy of being recommended as an excellent dreſſing for a wheat crop." *Muſeum Ruſt. vol.* IV. *pag.* 339.

Turf ASHES, the aſhes procured by burning turfs, or the parings of the ſurface of heathy and mooriſh land. *See the article* BURN-BAKING.

Theſe parings, or turfs, are cut in a dry ſeaſon, and ſet up to dry thoroughly, leaning one againſt another; and, when dry, are piled into ſmall heaps or piles, about a quarter or half a load, in each, carried up exactly ſquare to a certain height, and then drawn up gradually in a pyramidical manner, ſo as to throw off any accidental ſhowers. In a very dry ſeaſon even the covering of theſe piles may be carried home, and ſtacked or houſed indiſcriminately with the reſt; but in a wetter ſeaſon it is uſual to ſeparate and dry thoſe topmoſt turfs, if the weather allows, and to ſtack them ſeparately, to be uſed on the tops of fires, when large, as dampers. A ſtout labourer will, in a day, cut two waggon loads of theſe turfs. The women and children can ſet them up to dry, and the women can pile them up.

Theſe aſhes, (in the moors of Yorkſhire, where, as the Rev. Mr. Comber informs us they are greatly uſed, the principal firing being turfs) are carried out daily, or once in two or three days, to the dunghill; and the farmer takes the opportunity of his firſt leiſure towards the end of the year, to carry them out to his meadow land, on which he lays them thicker or thinner, as he has more or leſs land which he apprehends to want them, or more or leſs of them. The firſt rains waſh them in, and the next ſummer never fails to ſhew their good effect.

It will be eaſily imagined, that as theſe aſhes are much finer, or more pulverized than thoſe of coals, ſo they more inſinuate themſelves into the ſoil, but are, in their effects, much leſs laſting. However, as every year brings a conſiderable ſupply, the farmer is leſs concerned that they are not a laſting manure.

In the moors of Yorkſhire, the farmer is ſo ſenſible of the efficacy of theſe aſhes, that it is become a proverb among them, "The better fire, the richer farmer." In conſequence of this principle, the farmer endeavours to procure all the aſhes he can from the cottagers who have no land. And hence a happy connection ariſes; for the poor cottager finding the article of carriage the chief part of the expence of his fuel, is wiſe enough to bargain with the farmer to bring him home ſuch a quantity of his turfs in conſequence of his aſhes.

Some farmers lay theſe aſhes on their ground in the ſpring; and, if ſhowers follow, they will have their effect in the ſummer crop, though not ſo great as if they had been laid on at the end of the year. It muſt however be remarked, that he who lays on his aſhes in the ſpring, lays on what has been very lately made in the winter; and he who lays on at the latter end of the year, lays on what has been evaporating during the whole ſummer; ſo that it is not eaſy to ſay which method is the better. *Muſeum Ruſticum, vol.* V. *pag.* 311.

ASPEN-TREE, a ſpecies of the poplar, and called by botaniſts, *populus foliis ſubrotundis dentato angulatis utrinque glabris.* Poplar-tree with roundiſh leaves, having an angular indenture, and ſmooth on both ſides.

The leaves of this tree ſtand upon long ſlender foot-ſtalks, ſo as to be ſhaken by the leaſt wind, from whence it has been called the trembling poplar, or aſpen-tree.

The method of cultivating this tree is the ſame in every reſpect as that of the abele-tree. *See* ABELE-TREE.

ASS, a creature well known in moſt parts of Europe, and proves very uſeful in many reſpects, if taken proper care of.

The horſe is trained up, great care is taken of him, he is inſtructed and exerciſed; while the poor aſs is left to the brutality of the meaneſt ſervants, and the wantonneſs of children, that ſo far from improving, he muſt be a loſer by his education: and indeed had he not a large fund of good qualities, the manner in which he is treated is ſufficient to exhauſt them. He is the ſport, the but, and the drudge of the vulgar; who, without the leaſt thought or concern, drive him along with a cudgel, beating, overloading, and tiring him. We do not remember, that, if there were no horſes, the aſs would be conſidered, both with regard to himſelf and us, as the moſt uſeful, moſt beautiful, and moſt diſtinguiſhed of animals. Inſtead of being the firſt, he is now the ſecond; and from this accident alone he is held in no eſtimation. It is the compariſon that degrades him: he is conſidered, not in himſelf, but relatively to the horſe. We forget that he is an aſs; that he has all the qualities of his nature, all the gifts annexed to his ſpecies; and think only on the figure and qualities of the horſe which are wanting in him, and which it would be improper for him to have.

By his natural temper he is as humble, as patient, and

and as quiet, as the horſe is proud, fiery, and impetuous; he bears with firmneſs, and perhaps with courage, blows and chaſtiſements. He is ſober, both with regard to the quantity and quality of his food, contenting himſelf with the moſt harſh and diſagreeable herbs, which the horſe and other animals, will not touch. In water he is very nice, drinking only of that which is perfectly clear, and at brooks with which he is acquainted. *Buffon's Hiſtoire Naturelle, tom.* IV.

The aſs, though a contemptible creature, is very ſerviceable to many that are not able to buy or keep horſes; eſpecially where they live near heaths or commons, the barreneſt of which will keep them, being contented with any traſh, dry leaves, ſtalks, thiſtles, briars, chaff, and any ſort of ſtraw is excellent food for them; they require very little looking after, and will ſuſtain labour, hunger, and thirſt, beyond moſt creatures. They are ſeldom or never ſick; and endure longer than any other creature. They may be made uſe of to plough light lands, to carry burdens, to draw in mills, for which they are very excellent, to fetch water, or any other odd things. They are very uſeful for their milk, which is an excellent reſtorative in conſumptions, and other weakneſſes: but they would be of much more advantage were they uſed, as they are in foreign countries, for the breeding of mules. *See the article* MULE.

The ſhe-aſs, if you have any regard to their breed, ſhould be covered between the months of March and June. The beſt age to breed from is from three years old to ten, and you ſhould let the young aſs ſuck two years, and not work them till they are three years old.

Thoſe are reckoned the beſt ſhaped that are well ſquared, have large eyes, wide noſtrils, long necks, broad breaſts, high ſhoulders, a great back, ſhort tail, the hair ſleek and of a blackiſh colour: their ſkins make the moſt durable ſhoes of any ſort of leather. *Mortimer's Huſbandry, vol.* I. *pag.* 222.

ATMOSPHERE, the vaſt body, or collection of air which ſurrounds the earth to a very conſiderable height.

Clouds, which are precipitated in drops of rain for the ſervice of mankind, do not conſiſt wholly of watery particles; for beſides aqueous vapours and what theſe contain, there are raiſed from the ſurface of the earth into the air, ſulphureous and ſaline particles, which are alſo carried up into the clouds, and mixed with the aqueous vapours. Here we have a mixture of all ſuch ſubſtances, as it were, in their extremely ſmall parts, floating in the air together, and the effects of theſe ſulphureous and ſaline particles, thus mingled with aqueous vapours, are ſometimes very ſenſible, eſpecially in thunder and lightning; when the ſulphureous and nitrous particles taking fire, by the motion ariſing from heat, break out with the violence of flaſhes and noiſe, very much reſembling the effects of gunpowder.

Another proof that there are nitrous particles raiſed into the air, we have in the nouriſhment which rain, replete with theſe ingredients, gives to plants, more than any other water; and alſo from the collection of nitre, or ſaltpetre, in heaps of earth, out of which theſe principles derived from rain are known to be extracted, if theſe heaps of earth be expoſed to the air, ſo as to keep the wet weather from ſpoiling the operation. It is alſo a convincing argument, that theſe nutritive ingredients are of conſequence in vegetation, by plants in water refuſing to grow in droughty weather, notwithſtanding they have ſuch plenty of moiſture; from their being abſolutely at a ſtand when rain has been long a ſtranger to the earth, they are plainly ſeen to go forward with the buſineſs of vegetation, like thoſe plants which have been deprived of motion or growth, when the fine ſhowers deſcend, and continue to do ſo for ſome time.

Here then, in both caſes of the plants in a pond, there is water, but there are only in one theſe vegetative principles, which give motion to the plants, and conſequently thoſe ingredients are abſolutely neceſſary to vegetation; and therefore we may conclude, that water, when properly dilated by fermentation at the roots, is only an aſſiſtant to plants, in applying thoſe neceſſary principles, or helping to conduct them through the tubular interſtices of the fibres, or to float the nitrous particles through the whole ſyſtem of the operation in motion, or growth of vegetables, and not the food itſelf, or any ſort of nouriſhment when diveſted of thoſe principles. Whether, therefore, the ſyſtem of exceeding fine fibres, or tubes of a plant at a ſtand in a pond, in a very droughty ſeaſon, admits that water undilated, for want of nutritive, or fermenting principles, into its body, during the great want of rain; or whether it abſolutely refuſes to imbibe, or cannot attract, for want of a finer diviſion of its parts, any of it, as there are in it no nutritive ingredients, does not ſeem to admit of any doubt in favour of the latter queſtion, which, if true in nature, may poſſibly be of ſervice in the growth of ſome ſorts of plants, and perhaps ſave much trouble in attempting to force others forwards with ſome ſort of water.

Since it is plain, that there is a vaſt quantity of nitrous, ſulphureous, and bituminous matter all over the ſurface of the earth, and that plants and animals abound with volatile ſalts, we need not wonder that the heat of the ſun fills the air with ſuch fine particles, and all ſorts of unctuous exhalations, by firſt expanding them, after which they riſe till they meet with air and other mixtures of the ſame ſpecific gravity. What are uſually called *ignes fatui*, ſeem to conſiſt of a more unctuous ſubſtance than other exhalations, for we find their oily particles are eaſily fixed, but not ſo ſoon ſpent as thoſe of ſulphur and nitre. Shooting ſtars are improperly ſo called, becauſe they are nothing more than exhalations kindled in the air; and if a long train of ſubſtances take fire at once, it is commonly termed a *dart*; and if there be many, and they continue in the ſame place, they are then called *beams*.

Thus we plainly ſee how full the atmoſphere is of theſe rich ingredients for the buſineſs of vegetation; and becauſe they are of ſuch vaſt conſequence to the growth of plants, we will enumerate the ſources of them upon the frame of the globe; from whence the ſun and wind borrow them, in order to diſperſe them properly in the air, that they may intimately mix, and deſcend with the rain drops, and ſo be conveyed to the mouths of the fibrous tubes of plants with the greateſt care and ſkill; from theſe ingredients firſt leaving the ſurface of the earth, through the whole proceſs of their various motions, configurations, and combinations, till they are prepared in the moſt exquiſite manner to be received into the bowels of vegetables, which we plainly ſee ſtand in great need of them, as without their friendly aſſiſtance, or ſome compoſitions of dung to reſemble them, they are unable

unable from water and earth alone to get forward to maturity.

Salts are of various kinds, but all have a ſharp pungent taſte, though not all alike; and of theſe ſome are dug out of the earth like ſtone out of a quarry; others are made by art, by letting the ſea-water into ſhallow pits on the ſhore, and continue there till the aqueous particles are exhaled by the ſun and wind, and then the ſalt remains at the bottom. The ſalt is in its nature the ſame in both caſes; for the ſaline particles are not made by art in the combination of ingredients to imitate it; they are only ſeparated from the watry particles wherein they floated. The qualities of this excellent ingredient in vegetation are, that it eaſily diſſolves, and melts readily in the open air, if it be refined from all heterogeneous matter; when the water wherewith it is entangled is any ways drawn off, there remains a groſs ſediment, but the finer parts are carried away with it; this ſediment is the only part the fire cannot melt, but reduces it to a calx.

This facility of the finer parts ſwimming, as they are ſpecifically lighter than water, contributes to the benefit of plants; or rather theſe fine ſaline particles are of the ſame ſpecific gravity with the water; that they may intimately mix with it, and be carried in thoſe vapours through all the neceſſary ſtages, till they return to the earth again. This quality of melting and diſſolving in water and air, ſets the finer parts at liberty, and prepares them to take wing with the common exhalations. And yet the ſediment, or groſſer parts, which are left behind, have their excellent uſes in helping the embrios of plants to ſend out their fibrous tubes, in ſearch after more refined particles, which either adhere to the ſuperficies of the particles of earth, or are contained in their internal pores.

Nitre, of which there are ſeveral ſorts, natural and artificial, the former refining itſelf, and the latter refined by art, it is a kind of ſalt, which eaſily takes fire, but like ſea-ſalt is eaſily reducible to a calx. The vapours, or particles of nitre, when they deſcend for the uſe of plants, are found to contain abundance of ſpirits; for the nitre, as a ſalt, is impregnated with them, which render it volatile, and the fluid extracted from it is very ſharp and corroſive. The calx to which nitre is reducible, as well as the calx of common ſalt, has its excellent uſe in vegetation; and when it is reduced by fire to this ſtate, it then takes the name of fixed ſalt, or rather the aſhes of ſalts: the benefit of this calcination to land is manifeſt from the aſhes of burnt vegetables, and other natural bodies reducible to a calx: for the rich principles, or food, if we may call it ſo, of vegetables, are contained more or leſs in all bodies, whoſe parts can be thus ſeparated, as is evident from the operations in chemiſtry, which reduce bodies to their component parts, by the help of fire.

Sulphur is a liquid claimmy ſubſtance, whoſe parts are ſoon ſeparated, and riſe up into the air with other vapours, and ſoon occaſions violent motions in the atmoſphere, and becomes entombed in the aqueous particles, and is with the rain brought down to the plants. Bitumen is pretty much of the ſame nature with ſulphur, and with it is found in great plenty in moſt bodies, but in the moſt remarkable manner, and in the greateſt quantities, in pit-coal; yet not in equal quantities, as ſome coals burn better than others, and conſequently may contain more or leſs of theſe principles, which are apt to burn. Naptha is a kind of bitumen, and the only difference is, that it takes fire ſooner than bitumen is obſerved to do, and is not ſo eaſily quenched; and this facility of admitting the heating particles, which throw theſe inflammatory bodies into a ſpeedy motion internally, is of great uſe in the different degrees of the plant's growth.

Maltha ſeems to be a ſpecies of naptha; its properties, as they appear to common obſervation, are, that if it touches any thing, it ſticks ſo faſt to it, as not eaſily to be ſeparated; and water thrown on it in moderate quantities, does but the more inflame it, and earth alone is able to quench it. This valuable ingredient, when it deſcends in the drops of rain, adheres very intimately to the internal parts of the ſoil, both in the ſuperficies and the concave parts of the pores; and other deſcents of rain increaſe the motion of the internal parts of the particles of maltha, and thereby promote a fine dilatation in the tubular interſtices of the fibres of plants, and duly contribute to the acceleration of that motion in them, which is neceſſary to the different ſtages of their growth and nouriſhment. Before the fine parts of the maltha are in readineſs, or duly prepared by moiſture, and their well regulated fermentation, and while it is waiting for the deſcent of more rain, it is diveſted of all internal motion, and confined as a priſoner, till the other requiſites to the plant's welfare are properly aſſembled, and ready to perform their offices.

Theſe are the chief materials which give motion to plants, and of which the latter are found to conſiſt, when they are analized, unfolded, or ſeparated into their component parts by chemiſtry. The profeſſors of that art call the volatile ſpirits, ſulphur, and ſaline particles, the active principles; becauſe theſe, when duly prepared, and exactly applied to the mouths of the fibres, become the ſole agents, and by their continual motion, cauſe the whole action of the plant.

The vapours thus raiſed from the ſurface of the earth, become the original matter of all meteors, or heterogeneous ſubſtances, fit for the production of the vegetable world; and conſequently an inſtrument in the wiſe appointment of Divine Providence, for the preſervation of man, and all ſubordinate animals. When theſe heterogeneous vapours are thus lifted up above the earth, one degree of cold condenſes them into larger globules, which then becoming ſpecifically heavier than the atmoſphere, fall in drops of rain, and bring down all thoſe treaſures entombed in them. A greater degree of cold produces a coagulation of the heterogeneous vapours, which ſhoot like ſalts into various forms, united into certain angles, and make the flakes of ſnow, which ſtill contain the nutritive principles.

A third, or ſtill greater degree of cold, combines the vapours into a harder ſubſtance, wherein the valuable ingredients are intombed, and they deſcend in what we call hail; but if the cold condenſes the vapours before they riſe high above the ſurface of the earth, they will be unable to aſcend, but will hover about, and fill the lower part of the atmoſphere with what is uſually called a fog, or miſt; and if the cold be ſtill more intenſe, the miſt is frozen to every twig and blade of graſs in form of a white incruſtation, which is called rime. When the air in the day-time is warm, and the vapours buoyed up in it are too fine to be then viſible, they will be con-

denſed

denſed by the coolneſs of the evening, and deſcend on the vegetables in the form of dew: and if the evening of ſuch a fine day be cold enough to freeze, then inſtead of a dew, the ſurface of the ground will be covered with what is commonly called a white froſt. Theſe are the various ways appointed to bring down again upon the earth the treaſures that were taken from it, in order to be prepared and properly ſpread over the globe, by methods and contrivances equally beautiful and ſurprizing; and all this for the ſupply of needy man, who is, when theſe bleſſings are for a conſiderable time with-held from him, turned to deſtruction.

But amongſt the riches of the atmoſphere for the production of vegetables, we muſt not forget the conſequences which the air itſelf is of to them, as we have already obſerved under the article air. *See* AIR. *Randall's Semi-Virgilian Huſbandry.*

AVENUE, a walk planted on each ſide with trees, leading to an houſe, wood, &c.

The Engliſh elm will do in all grounds, except ſuch as are very wet and ſhallow; and this is preferred to all other trees, becauſe it will bear cutting, heading, or lopping in any manner, better than moſt others. The rough or ſmooth Dutch elm is approved by ſome, becauſe of its quick growth; this is a tree that will bear removing very well; it is alſo green almoſt as ſoon as any plant whatever in ſpring, and continues ſo as long as any, and it makes an incomparable hedge, and is preferable to all other trees for lofty eſpaliers. The lime is valued for its regular growth, and fine ſhade: the horſe cheſnut is proper for all places that are not too much expoſed to rough winds. The common cheſnut will do very well in a good ſoil, and riſes to a conſiderable height, when planted ſomewhat cloſe, though, when it ſtands ſingle, it is rather inclined to ſpread than grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild ſtate, but it is leſs to be choſen for avenues than the before-mentioned, becauſe it does not bear tranſplanting well, but is very ſubject to miſcarry. Laſtly, the abele is fit for any ſoil, and is the quickeſt grower of any foreſt-tree. It ſeldom fails in tranſplanting, and ſucceeds very well in wet ſoils, in which the others are apt to fail. The oak is but little uſed for avenues, becauſe of its ſlow growth.

The old method of planting avenues was with regular rows of trees, and this has been always kept till of late; but we have now a much more magnificent way of planting avenues: this is by ſetting the trees in clumps or platoons, making the opening much wider than before, and placing the clumps of trees about three hundred feet diſtant from one other. In each of theſe clumps there ſhould be planted either ſeven or nine trees; but it is to be obſerved, that this is only to be practiſed where the avenue is to be of ſome conſiderable length, for, in ſhort walks, this will not appear ſo ſightly as ſingle rows of trees. The avenues made by clumps are fitteſt of all for parks. The trees in each clump ſhould be planted thirty feet aſunder, and a trench ſhould be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them. *Miller's Gard. Dict.*

AVER, a general name for a labouring beaſt of any kind.

AVERAGE, a term uſed by the farmers of many parts of England for the breaking up of corn fields, otherwiſe called eddiſh, or roughings.

AVER-CORN, a name formerly given to the corn conveyed to the lord's granaries by his tenants.

AVER-LAND, the land ploughed by the tenants for the uſe of their lord.

AUGUST, the eighth month of the civil year.

This month returns the countryman's expences into his pockets, and encourages him to another year's adventure. If it proves dry, warm, and free from high winds, it ſaves a great deal of the huſbandman's expence.

You may yet twifallow, alſo lay on your compoſt or ſoil, as well on your lands intended either for barley or wheat.

Carry wood, or other fuel home, before winter approaches, and renders the roads deep and heavy.

Provide good ſeed, and well picked, againſt ſeed-time.

Put your ewes and cows you do not like to fatten.

This is generally the principal harveſt-month for all ſorts of grain, therefore make the beſt uſe of good weather while you have it.

About the end of this month you may mow your after-graſs, and alſo clover, ſaintfoin, and other French graſs. Geld lambs, and make the ſecond return of your fat ſheep and cattle. *Mortimer's Huſbandry, vol.* II.

AUGRE, an inſtrument much uſed by carpenters, wheelwrights, &c. for boring large round holes. It conſiſts of a wooden handle and an iron blade, terminated with a ſteel bit.

A common augre may be very uſefully applied to try the nature of the under ſoil, and layers of earth, in order to know what may be expected from them, with regard to the vegetation of plants. In order to this three augres will be neceſſary; the firſt of them about three feet long; the ſecond ſix; and the third ten. Their diameters ſhould be near an inch, and their bits large, and capable of bringing up part of the ſoil they pierce. An iron handle ſhould be fixed croſs-ways to wring it into the earth; from whence the inſtrument muſt be drawn up, as often as it has pierced a new depth of about ſix inches, in order to cleanſe the bit, and examine the ſoil. But the borer, an inſtrument invented by the marquis de Tourbilli, is much better adapted to this operation. *See the article* BORER.

AVIARY, a place ſet apart for the feeding and propagating birds. An aviary ſhould be ſufficiently large as to allow the birds a conſiderable freedom of flight; and turfed, to avoid the appearance of foulneſs on the floor.

AUMBRY, *Ambry*, or *Aumery*, a pantry, or cupboard to ſet victuals in.

AWMS, the beard of wheat or barley. The word is, in ſome parts of England, pronounced *ails*.

AXIS, or *axle-tree*, of a waggon, cart, &c. is the ſtrong piece of wood or iron, which ſupports the carriage, and round the extremities of which the wheels turn. *See the articles* CART *and* WAGGON.

B.

BAC

BACK-SINEW, in a horſe, is that ſtrong ſinew extending along the hinder part of the ſhank from the knee to the heel, into which it is inſerted.

The back ſinew is ſo very ſubject to be hurt or ſtrained, that it is conſidered as one of the moſt common and uſual accidents that happens to a horſe; it generally proceeds from hard riding upon dry grounds, and from other cauſes, where the roads are ſtony and hard, and ſometimes where they are poachy.

It is eaſily perceived by the ſwelling of the ſinew, which ſometimes extends from the knee down to the heel; and when it is ſo, a horſe does not care to ſet his foot even upon the ground; but, for the moſt part, in his ſtanding, ſets it before the other.

The uſual way of curing this malady, is with cold charges, which often ſucceed very well, if frequently renewed; ſome uſe curriers ſhavings bound round the knee with a bandage, and this alſo anſwers very well in ſome caſes; but there is nothing either ſo ready or efficacious as vinegar or verjuice mixed with bole, being often in a day ſoaked well into the ſinew warm; and if any thing of the lameneſs or ſwelling remains after this, and after the heat and inflammation is gone off, a mild bliſter, that has nothing corroſive in it beſides the cauſtic ſalt of the flies, will, generally ſpeaking, effectuate a cure, and bring the ſinew fine.

When hot and relaxing oils mixed together are uſed to the back-ſinew, which many practitioners are fond of, becauſe they ſometimes ſucceed in horſes that have their ſinews ſtrong and rigid, yet they are apt to engender wind-galls of a bad kind, or make the veins on each ſide the ſinew to be full and gorged; and horſes have been known to be lame for two or three years together with theſe varixes in the veins. Bliſtering in this caſe has very little or no effect, firing through the vein till the blood comes being only ſufficient to remove that weakneſs. After the firing, the whole leg from the knee down to the heel, and all the hollow places on both ſides, muſt be charged with a good ſtrengthening plaiſter, which will perfect the cure, eſpecially if the horſe be turned to graſs for a month or five weeks, or, in the winter, if he run a little while in a ſmooth yard, where he has good dry litter. *Gibſon on the Diſeaſes of Horſes.*

BACON, the fleſh of a hog dried in the ſmoke.

A writer in the *Muſeum Ruſticum*, vol. III. pag. 234, has given us the following method of making bacon in Somerſetſhire.

The ſeaſon for killing hogs for bacon is between September and Chriſtmas. When you kill a large hog for bacon, lay the ſides in the ſalting-troughs, and ſprinkle

BAK

them pretty heavily with bay-ſalt: then leave them twenty-four hours to drain away the blood, and ſome of the over abounding juices.

After this take them out, wipe them very dry, and throw away the draining. Then take ſome freſh bay-ſalt, and heating it well in a large iron frying-pan, rub the meat very well with it; repeating this work every day for four days, and turning the ſides every other day.

If the hog be large, keep the ſides in brine (turning them ten times) for three weeks; after which take them out, and let them be thoroughly well dried in the uſual manner: if they are not fully dried, they will neither keep ſo well, nor eat ſo fine.

BADGER, the name of an animal, common in many parts of England; and called by ſeveral names, as a gray, a brock, a boreſon, or a bauſon.

Badgers are almoſt as pernicious a creature to the huſbandman as the fox, though not ſo ſubtile, nor can they ſo eaſily catch their prey; but for what they can catch, as new fallen lambs, young pigs, and poultry, they are as bad. The way to catch them is with a ſpringe, or a ſteel trap, or to dig a pit acroſs their path five feet deep, and about four feet long, making it narrow at the top and bottom, and wide in the middle. This muſt be covered with ſome ſmall ſticks and leaves, ſo as that the badger may fall in when he comes upon it. Some hunt them into their holes in a moon-ſhine night, and then dig them out. *Mortimer's Huſbandry, vol.* I. *pag.* 314.

BAG, a name given by farriers to a medicine for recovering a horſe's appetite when loſt. It is done in this manner: they take an ounce of aſſa fœtida, and an equal quantity of the powder of ſavin; theſe ingredients they put into a bag, which they faſten to the horſe's bits, keeping him bridled for two hours, two or three times a day: as ſoon as the bag is taken off, he will immediately eat. The ſame bag will ſerve a long time.

BAKING *of land.* If ſome ſorts of ſtiff and binding land be ſown dry, and a ſcud of rain falls before the earth has time to ſettle, it is obſerved that the cruſt of ſuch land will bake, ſo that the corn cannot come through, to the great damage of the crop; this evil does not happen if ſuch a ſcud of rain be followed by cool cloudy weather, and not hot ſun-ſhine; for then the earth will not be ſo hollow as to be baked. The beſt way to prevent this is, to roll it immediately after ſowing, which faſtens the earth together, whereby the ſun has not that power of piercing into it, and conſequently not of baking it.

Land of this kind ſhould, therefore, be ſown as often as poſſible with winter corn, ſuch as wheat and vetches; for though, if wet follows the ſowing, the ſun is not

ſtrong

ſtrong enough at that time of the year to ſcorch the ground up, and bind it; and it is obſerved, that this ſort of ground has been always lucky for vetches, probably for the above reaſon. *Liſle's Obſervations in Huſbandry, vol.* I. *pag.* 26.

BALK, a piece of land which has been either caſually overſlipped, or not turned up in ploughing; or carefully left untouched by the plough, for a boundary between lands, or ſome other uſe.

BALK, alſo ſignifies the ſummer-beam, or dorman of a houſe.

BALKS, or *bawks*, implies poles laid over a ſtable, or other building, for a roof.

BALM. *See the article* BAUM.

BANDS, a ſmall parcel of the longeſt wheat taken from the grips, and twiſted together at the ear ends, for binding the wheat into ſheaves.

The bands ſhould be laid in the morning, that they may not crack; for the ſtraw will not twiſt after the ſun is up, but will be brittle, and break off below the ears. The turning of three or four of the ſtubble or bottom ends of the ſtraw to the ears of the band, helps greatly to add to its ſtrength and toughneſs.

The bands for binding up the ſheaves ſhould not be ſpread but in fair weather, becauſe being preſſed down by the grip or two which it is neceſſary to lay upon them to keep them in their places, and prevent their being untwiſted by the ſun, they will grow ſooner than any other part of the corn, if rain ſhould come; for they cannot dry on account of their lying undermoſt. But though the bands muſt always be made while the morning dew is upon them, the ſheaves ought by no means to be bound up wet: if they are, they will certainly grow mouldy.

Farmers do not always attend ſufficienly to the binding up of their ſheaves, but ſuffer the reapers, for diſpatch, to tie the bands juſt underneath their ears, inſtead of binding them at the other end; the conſequence of which is, that they will hardly hold together to be flung into the cart, and will certainly be in great danger of falling to pieces before they are thraſhed.

If a little rain be foreſeen in harveſt time, it is beſt to bind the grips into ſheaves as faſt as they are made; becauſe ſmall ſhowers will wet the ſingle grips ſo much, that they cannot be bound up, and theſe ſhowers may be the fore-runners of greater rains. The ſheaves being bound will ſoon dry after ſuch wet. But if a hard rain is foreſeen, the beſt method is not to bind the wheat into ſheayes, becauſe they will then be wet to the bands, and muſt be opened again. Mr. Liſle tells us, that one of his neighbours to whom this happened, unſheafed ſome of his wheat to dry it, and opened it and turned it ſo often, that the ears broke off, whereby he loſt half his corn; caution therefore ought to be uſed in this caſe, leſt by curing one evil we create a worſe. *Liſle's Obſervations in Huſbandry, vol.* I. *pag.* 333.

BANDS *of a ſaddle* are two peices of iron, flat, and three fingers broad, nailed upon the bows of a ſaddle, one on each ſide, contrived to hold the bows in the ſituation that makes the form of a ſaddle.

BANE, in ſheep, the ſame as rot. *See the article* ROT.

BANGLE-EARS, an imperfection in a horſe, which may be remedied in the following manner: place his ears as you would have them ſtand, aud then with two little boards, or pieces of trenchers, three fingers broad, having two long ſtrings faſtened to them, bind the ears ſo faſt in the places where they ſtand, that they cannot ſtir; then behind the head, and the root of the ears, you will ſee a great deal of empty, wrinkled ſkin, which you muſt pull up with your finger and thumb, and clip away with a pair of ſharp ſciſſars all the empty ſkin cloſe by the head; then with a needle and red ſilk, ſtitch the two outſides of the ſkin together, and heal the wound with a mixture of honey and turpentine: when this is done, take away the ſplints that hold up the ears, and in a little time they will keep the place where you fixed them without alteration.

BANK, a heap of earth piled up to keep out the water of a river, lake, or the ſea.

Sloping banks are the beſt ſecurity againſt the encroachments of the ſea, of rivers, or of lakes; making proper allowance for the weight of water, and violence of the waves. Theſe banks ſhould be raiſed about two feet above the level of the water at the higheſt tides, and their ſtrength ſhould be proportioned to the force of the water intended to be fenced off. When a river is too much confined, it ſwells conſiderably upon a flood, and conſequently requires banks of greater height and ſtrength than would otherwiſe be neceſſary; though it will ſometimes break even theſe, and carry all before it, if a ſufficient ſpace be not allowed for the increaſe of its water: but when ſuch a ſpace is left, the waters ſpread, and ſeldom riſe more than two or three feet above their uſual level. In ſome caſes a breadth of fifteen or eighteen feet on each ſide may do; but in others, fifty, eighty, or an hundred feet, or perhaps ſo many yards, according to the largeneſs of the river, muſt be left open for that purpoſe. It is beſt to err on the ſafe ſide; eſpecially as the ground that is left between the banks and the river will be far from being loſt; for it will afford good grazing in the dry ſeaſons of the year, and may be planted with oſiers, and willows, and other trees of that kind; but theſe ſhould never be planted upon the banks, leſt the winds ſpoil and tear them, by ſhaking the trees, and looſening their roots.

In the iſle of Ely, it is common to ſee great banks diſtant one or two hundred yards on each ſide from the channel of the river; and when they are ſo made, they are always ſafe: but where the diſtance between the banks is narrow, there, and there only, the banks are in danger of being broken down, and the country of being overflowed.

If a conſiderable body of water is to be guarded againſt, dig a trench ten or twelve feet wide, and two or three deep, or more, according to the height of the bank required. Lay all the ſoil that is taken out of this trench, on that ſide of it which lies towards the water, and leave a ſpace of two or three feet between the trench, and the foot of the bank. Let the bank be made with an eaſy ſlope of fifteen or eighteen feet in length towards the water, allowing the ſlope two and a half, or three feet fall to one in height; but the inſide ſlope need not be more than eight or nine feet, which is a foot and a half ſlope to one foot perpendicular. The bank thus raiſed five or ſix feet high, according as the floods require, will be two feet wide at the top, where it ſhould be well flatted, that people may walk upon it. Let it then be covered with gravel dug out of the channel of the water, by which means the river will be

deepened, and the bank rendered ſtronger; and to add to the latter, ſow it very thick with graſs-ſeed. This will be found much better than turfing it with the ſods taken from off the trench, or ſome neighbouring ground; becauſe the ſods are apt to ſhrink, open, and part from one another in dry weather, and are then liable to be waſhed away with the next flood; whereas in this much cheaper way, a cloſe covering of graſs, even long enough to mow, will be formed in a month or two: far fitter than ſods to break the ſurface of the bank; for any tolerable ſoil may be very ſoon brought to have a coat of graſs, by only raking it fine, and ſowing it with graſs-ſeeds. In a week or ten days in the ſpring, or ſummer, the graſs will be up, and grow to ſuch a height in a month or ſix weeks, as to be fit for mowing.

Some have attempted to guard againſt inundations by building walls of ſtone and lime, where the materials are in plenty. The great danger here is their being undermined, and that chiefly by the water's ſtriking with force againſt the bottom, upon meeting with reſiſtance from the wall. But this may be eaſily guarded againſt by laying a row of flat ſtones lower than the bottom of the river; for the water ſtriking againſt theſe ſtones, turns off without any danger to the foundation.

The broad trench within the bank, beſides affording materials for making the bank and ſlopes, is attended with the farther advantage of ſerving for a drain to the inland ground. Theſe trenches ſhould always be carried as far as the banks, particularly when theſe are intended to fence off a riſing tide; and in the loweſt part of the ground a ſluice with a valve, flap-door, or flood-gate ſhould be placed in the bank, where it will both diſcharge the inland water, when the tide is out, and prevent its flowing in. The ſeaſon of the year freeſt from floods ſhould be choſen for making theſe banks, that the bank may have time to ſettle and grow firm before the heavy rains come on. It is alſo adviſable to be as expeditious as poſſible in this work. For if it be begun in a dry ſummer, and finiſhed in a month or two, there will be little danger of being interrupted by extraordinary floods or violent ſtorms, either of which might do more harm in one day, than could be repaired in a fortnight.

The exact dimenſions of the bank, and of the ditch within it, cannot be preciſely aſcertained by any general rule; becauſe both tides and floods riſe to different heights, and have different force, in different places and circumſtances. The ſtrength above-mentioned may be ſufficient for banks in common caſes; but in others, where a great body of water, or a powerful tide is to be oppoſed, they may be, as the memoirs of the Berne Society (*tom.* II. *part* II. *pag.* 262) adviſe, four feet or more wide at the top, with a baſis proportioned to their height, as three and a half are to one; or, if it be deſired to make them ſtill more ſolid, as four to one; ſo that if the bank be four feet and a half high, its baſis in the former caſe will be fourteen feet wide, and in the latter eighteen.

The Dublin ſociety for the advancement of agriculture informs us (Numb. XVII. *for April* 1737) that "Lord Limerick has recovered between four and five hundred acres of very rich ſalt marſh, at Dundalk in Ireland, and effectually ſecured them from the ſea, by ſuch banks as are above deſcribed; and by the ſame method many hundred thouſand acres have been recovered from the ſea in Cambridgeſhire, Lincolnſhire, and other parts of England; not to mention the low lands of Holland; which are indeed ſecured againſt the violence of the ſea by no other means.

"If there be a neceſſity for making banks on a ſtrand where nothing but ſand can be met with, thoſe banks ſhould be large, and the ſlope very broad and extended; and if graſs-ſeed will not grow on them, let ſea-weeds be planted. Theſe with ſticking furze, ſtraw, or loppings of trees, will help to keep the banks together."

But a better method, and more effectual, is given by Dr. Hales in the Philoſophical Tranſactions, from the experience of Dr. Wark, a clergyman in Scotland. The method conſiſts in fixing to the bottom of the channel, a breadth of furze proportioned to the force it is to reſiſt. The ſand or ſlime, as either abounds, will ſoon ſettle among the branches of the furze; and when the firſt bed of the furze is thus interwoven or covered, another bed of furze is to be laid on as before, and ſo on, till the bank is raiſed to a ſufficient hight. Dr. Wark aſſures us, that by this ſimple method a bank was made near Holy-iſland ſo ſtrong, that it became a bar againſt the ſea itſelf.

"It ſometimes happens, that the ſea flows in through a narrow gut or paſſage, by which the inland waters are diſcharged, and then extends itſelf, and covers a great deal of ground. When this happens, if the inland waters cannot be diverted into another courſe, ſince a paſſage muſt be left for their diſcharge; let a ſtrong ſluice be fixed in the loweſt part of the channel, with large piers of ſtone, running out for its ſupport, and a ſtrong foundation of wood or broad ſtones for the water to run over. When this is done, let the banks of ſand, or other ſoil near at hand, be made in the manner already mentioned, on each ſide of the ſluice.

"The reaſon why it is adviſed, in places where a ſluice is to be made, to begin the work by this rather than by the bank, is, that while the tides have liberty to flow in and out at a great breadth, the ſluice may be made in any part of the channel without being much incommoded by the tide; whereas if it be deferred till the banks on each ſide are made, the force of the tide, when confined to a narrow paſſage, will tear up all before it, and render the building of the ſluice impracticable: and upon the ſame account, the banks ſhould be begun at the loweſt part of the channel, and carried on from thence to the upper grounds.

"If, by any accident, the waters ſhould ſwell ſo high as to overflow and tear the banks, farther miſchief may be prevented by fixing with all expedition, a ſail-cloath, or ſheet of linen at the bottom of the bank, where the flood breaks in; for if this be done in time, the water will flow over the cloth, without waſhing away the bank.

"In every improvement, the expence ſhould be particularly conſidered. That of making banks in this method is ſmall. In low grounds the ſoil is ſoft, and dug with eaſe, and all the work may be done with the ſpade and ſhovel, without pick-axes, which muſt be uſed in upland ground; and the materials are on the ſpot. All the charge will be often more than repaid by the firſt years improved crop of graſs, and the ſafety of the meadows. The produce of ſucceeding years will amount much higher, and the huſbandman will be out of all danger for the future of having his lands overflowed and ſpoiled.

ſpoiled. Farmers have frequently ſuſtained more damage from the hay deſtroyed in one ſeaſon by floods, than the whole value of what it would have coſt them to incloſe and bank their meadows, and free them from all hazards."

BANNOCK, an oat-cake kneaded with water only, and baked in the embers.

BANQUET, in that ſmall part of the branch of the bridle that is under the eye, which being rounded like a ſmall rod, gathers and joins the extremities of the bit to the branch, and that in ſuch a manner, that the banquet is not ſeen, but covered by the cap, or that part of the bit which is next the branch.

To BAR *a vein*, implies an operation in farriery performed in the following manner: they open the ſkin above and below the place where the operation is to be performed, and after freeing the vein from the ſurrounding parts, they tie it at thoſe openings with two ligatures; after which they open the vein between the ligatures in order to diſcharge the blood. This operation is performed upon the veins of a horſe's leg, and other parts of his body, in order to ſtop the courſe, and leſſen the quantity of malignant humours that prevail there.

BARB, a general name for horſes imported from Barbary.

The cheſt of the barb is long and ſlender, riſes beautifully from the withers, his mane little, his head well ſhaped, ſmall, and lean; his ſhoulders flat and ſlender; his withers narrow and plump; his back ſtrait and ſhort; his flanks and ſides round, and not bellying out; his haunches firm and well ſhaped; his croop generally ſomewhat long, and his tail placed pretty high; his thigh well ſhaped, and ſeldom flat; his legs handſome, well ſhaped, and without long hair at the paſtern joint; his foot well made, but his paſtern often long.

Barbs are of all colours, but generally brown. They are ſomething negligent in their goings; but, properly encouraged, ſhew an amazing ſwiftneſs and vigour: they are very light and fit for running; and ſeem of all others the fitteſt to breed from. It were, however, to be wiſhed that they were a little taller, the largeſt barely exceeding fourteen hands; and one of fourteen hands and an inch, is very extraordinary. Experience has, however, ſhewn, that in England, France, &c. they get colts larger than themſelves. Among the barbs, thoſe from the kingdom of Morocco are accounted the beſt, except the mountain barbs. Thoſe of the reſt of Mauritania, are inferior to them, as are alſo thoſe of Turkey, Perſia, and Armenia. All horſes from a hot climate have a ſmoother coat than others. *Buffon's Hiſtoire Naturelle, tom.* IV.

BARBELS, or *barbs*, are excreſſences or knots of ſuperfluous fleſh, growing under the tongue, and may be ſeen by drawing it aſide.

They are cured by cutting them cloſe off, and waſhing the wounded part with brandy, or ſalt and water. *Bartlet's Farriery, pag.* 262.

BARBS. *See the article* BARBELS.

BARG, a horſe-way up a ſteep hill.

BARING *of trees. See the article* ABLAQUEATION.

BARK, the exterior part of trees, ſerving them for a ſkin or covering.

Dr. Agricola ſays, that the bark of a tree may be compared to the ſkin of an animal, which is deſigned for the preſervation of the inward parts. It is generally of a ſpongy texture, and communicates with the pith by a multiplicity of ſmall fibres paſſing between the capillary tubes, of which the wood conſiſts; ſo that the roots having imbibed the proper nutriment of the tree, it is carried up by the warmth of the ſun, through the fine arterial veſſels of the tree to the top of it; and being there condenſed by the cold, it returns by its own gravity down by the veſſels which lie between the wood and the inner bark, which perform the office of veins, and as it paſſes by leaves ſuch part of its juices as the texture of the bark will receive, and requires for its ſupport.

Some are of opinion, that the ſoft whitiſh rind, or ſubſtance which lies between the inner bark and the wood, performs the office of veins; and ſome call this a third bark, ſuppoſing it to differ from the other only in having its fibres cloſer; adding that this is the part which contains the liquid ſap, gums, &c. found in plants during the ſpring and ſummer months, and which hardening by degrees, is imperceptibly conveyed into the woody part of the tree, forming every year a new circle of wood between the bark and the trunk. Theſe circles are not equally thick, that circumſtance depending on the fertility of the year.

The bark of trees in general, and eſpecially that of the oak, contains a very rich ſalt, extremely uſeful in vegetation. One load of oak bark laid in a heap and rotted, after the tanners have uſed it for dreſſing their leather, will do more ſervice to ſtiff cold land, and its effects will laſt longer, than two loads of the richeſt dung. Mr. Miller ſays it is much better for cold, ſtrong land, than for light, hot ground, if it be uſed alone, as taken from the tan-yard; becauſe it is of a warm nature, and will looſen and ſeparate the earth ſo effectually, that, by only uſing it two or three times, a ſtrong ſoil, not eaſy to be wrought, will be rendered perfectly light and looſe: but by mixing it with earth of a nature contrary to that which it is intended to correct, and in a proportion ſuited to the nature of the ſoil it is to be laid on, it will prove a fine manure for almoſt any land; its ſalts being ſuch as will always fertilize the ground. Mr. Mortimer aſſerts, that it will alter and change the very nature of the ſoil, and turn it into a very rich black mould. *Mortimer's Huſbandry, vol.* I. *p.* 121.

It neceſſarily abounds in vegetable parts, derived from the tree to which it once belonged; and cannot but be ſtrongly impregnated with animal juices, as it lies a long time in the tan-vats, with the ſkins and hides of animals; circumſtances which muſt render it ſingularly beneficial to all poor lands.

If laid on graſs, it ſhould be ſpread ſoon after Michaelmas, that the winter rains may waſh it into the ground: for if it be laid on in the ſpring, it will be apt to burn the graſs, and, inſtead of improving, will do it a conſiderable injury for that ſeaſon. When uſed for corn land it ſhould be ſpread before the laſt ploughing, that it may be turned down for the fibres of the corn to reach it in the ſpring; for if it lies too near the ſurface it will forward the growth of the corn in winter; and in the ſpring, when the nouriſhment is chiefly wanted to encourage the growth of the plants, it will be ſo nearly conſumed, that the corn will receive very little advantage from it.

Mr. Bradley tells us, that he adviſed a gentleman to whom a conſiderable quantity of bark was left upon the

extirpation of the leaſe of a tan-yard, to lay ſome of it upon a piece of ſtubborn ſour land, which he did with ſuch ſucceſs, that his product was admired by all the gardeners and farmers in the neighbourhood. For ſuch ground, he thinks it ſhould be mixed with a ſandy ſoil; and that one third of bark to two thirds of ſand, will be a very ſufficient proportion for clays; laying on about one hundred and fifty cart loads upon an acre. *Bradley's Husbandry, pag.* 90.

All barks or rinds of trees, though not of ſo high a value as that of the oak, which is the ſort principally uſed by tanners, muſt of neceſſity enrich either corn or paſture ground, if broken into ſmall pieces, and laid upon it. They muſt needs be much richer than the mould or earth, uſually found in the bodies of old, large, hollow, willow-trees, though this is juſtly eſteemed very efficacious. *Worlidge's Husbandry, pag.* 84.

For the manner of making hot-beds with tanner's bark, *ſee the article* TAN.

BARK-BOUND, a diſeaſe common to fruit-trees, and may be cured by making a ſlit through the bark, from the top of the tree to the bottom, in February or March; and if the gaping be pretty conſiderable, fill up the rift with cow-dung. *Mortimer's Husbandry, vol.* II. *pag.* 85.

BARKING *of trees*, the operation of ſtripping off the bark or rind, particularly that of the oak, for the uſe of tanners.

It is neceſſary in our climate to perform this operation in the month of May, becauſe at that ſeaſon only, the brak is, by the great quantity of ſap, ſeparated from the wood. This alſo renders it neceſſary to fell the trees in that month; but by this method the timber is much leſs valuable than it would be if felled after the fall of the leaf.

BARLEY, a ſpecies of grain well known in England, and of which Mr. Miller has enumerated four ſpecies.

1. The ſpring barley, which has a double row of beards or awns ſtanding erect. This is the ſort principally cultivated in England, and of which the farmers make two ſorts, viz. the common, and the rath-ripe barley: but theſe two ſorts are in reality the ſame; for the rath-ripe is only an alteration of the common barley, occaſioned by being long cultivated upon warm gravelly lands. The ſeeds of this, when ſown in cold or ſtrong land, will the firſt year, ripen near a fortnight earlier than the ſeeds taken from ſtrong land, and therefore the farmers in the vales generally purchaſe their ſeed barley from the warm lands; for if ſaved in the vales two or three years, it will become full as late in ripening as the common barley of their own product: on the other hand, the farmers on the warm land are alſo obliged to procure their ſeed barley from the ſtrong land, otherwiſe their grain would degenerate in bulk or fulneſs, which, by this change, is prevented. This ſort of barley is eaſily diſtinguiſhed by the two orders of beards or awms, which ſtand erect; the rind is alſo much thinner, and therefore eſteemed better for making malt.

2. The long-eared barley, which is cultivated in many parts of England, and is an exceeding good ſort; but ſome farmers object to this barley, becauſe they ſay the ears being long and heavy, it is more apt to lodge. This ſort of barley hath its grains regularly ranged in a double row, lying over each other, like the tiles on a houſe, or the ſcales of fiſh. It has no beards or awms; but its rind is very thin, and therefore eſteemed for making malt.

3. The ſprat barley, called alſo Battledore, Fulham, and Patney barley, from the great quantities cultivated in the neighbourhoods of thoſe places, has ſhorter and broader ears than either of the former ſorts; the awms or beards are longer, which tend greatly to preſerve it from the bird, and the grains placed cloſer together. This ſeldom grows ſo tall as the other ſpecies; the ſtraw is alſo coarſer, and therefore not ſo good fodder for cattle.

4. The winter barley, called alſo ſquare-barley, bear-barley, or big, is ſeldom cultivated in the ſouthern parts of England; but in the northern counties, and in Scotland it is the general ſort ſown, as being much hardier than the other ſpecies. There are two ſorts of this barley, the one with four rows of grains, and the other with ſix, the latter of which is commonly diſtinguiſhed by the name of barley-big. The grain is large and plump, but the rind or chaff of it being thicker than that of either of the preceding ſorts, it is leſs eſteemed for making malt, and therefore not cultivated in the ſouthern parts of England, where the ſorts which are ſo much better for that purpoſe thrive ſo well.

Both the four and ſix rowed barley are generally ſown in the autumn, nearly at the ſame time with wheat, not only in temperate climates, but alſo in very cold countries; their hardineſs being ſuch as to bear the winter's froſts, even in the mountainous parts of the northern regions. In hot countries they are ſown in January, February, and March.

All the other ſorts are ſown in the ſpring of the year in a dry time; in ſome very light land barley is ſown early in March, but, in ſtrong clay ſoils, not till April, and ſometimes not till the beginning of May; but when it is ſown ſo late, if the ſeaſon does not prove very favourable, it is very late in autumn before it is fit to mow, unleſs it be the rath-ripe ſort, which is often ripe in nine weeks from the time of ſowing: though Mr. Liſle is of opinion, that this, in particular, ought to be ſown early, for otherwiſe it will grow very thin. He likewiſe thinks, that it ſhould be ſown on better ground than the other barley, becauſe as it ripens in a ſhorter time it may be naturally ſuppoſed to exhauſt the nutritive juices of the earth faſter than other corn. But it is ſaid by others, that theſe nutritive juices in almoſt any tolerable ſoil, will probably hold out long enough to feed a crop of ſo ſhort a ſtanding as this is, though they might not ſuffice for corn which ſhould remain longer upon the ground; and it is added, that about Patney in Wiltſhire, they ſow the pooreſt ſandy ground with rath-ripe barley. *Liſle's Huſbandry, vol.* I. *pag.* 271.

Mr. Liſle adds, that he himſelf in the year 1707, ſowed in Hampſhire, rath-ripe barley in very poor white ground, and ſome of the ſame corn in good ſtrong clay land. No rain fell to bring it up till June; after which there were frequent ſhowers, and plenty of rain till harveſt. His rath-ripe barley in the poor land was miſerably bent, broken in the ſtraw, and harled, or fallen down. In the ſtrong clay land, the ſame corn ſuffered the ſame injuries, though in a leſs degree: but the ſtraw and leaves of the rath-ripe barley in both places blighted, and were full of black ſpecks; their ears were thin, and their colour was loſt; while the plants of late-ripe barley in an adjacent field were free from theſe ſpots, and ſtood upright with

with good ſtrength. From this experiment he infers, that ſince the clay land in the hilly country of Hampſhire, though in good heart, cannot even, in a moiſt year, ſufficiently feed the ſtraw of rath-ripe barley, ſo as to enable it to ſtand upright, but ſuffers it to be languid and withering, this ſort of corn is not proper for ſuch places, and that it is better to ſow late-ripe barley, even though three or four horſes extraordinary be provided againſt ſowing time, in order to get the corn into the ground a week before May begins. *Liſle's Huſbandry, vol.* I. *pag.* 272.

Another important obſervation made on the ſame occaſion, by the ſame judicious farmer, was, that one half of the ſeed which fell deep came up without rain, while the reſt did not ſprout till after the rain came. The half which came up firſt, could not, by reaſon of the weakneſs of the ſtems, wait for the ripening of the latter edge-grown corn, in the ſame field; but its ſtraw bent, broke, and was entangled, and the ears buried themſelves among the broad clover ſown with the barley, ſo that he was forced to cut it; not being able to ſtay a week or ten days longer for the edge-grown corn to ripen: whereas the late-ripe barley ſtood ſo upright in its ſtraw, that the corn which came up firſt would ſtay ten days for the edge-grown corn.

The ſame gentleman had another evident proof, in the year 1706, that the ſtraw of the rath-ripe barley is thinner and weaker than that of the late-ripe. All his rath-ripe barley, of which he ſowed fifty acres in different ſorts of ground, and ſome of it ſide by ſide with late-ripe barley, crumpled down in the ſtraw, while the late-ripe barley of the ſame forwardneſs and growth, ſtood upright.

Upon the whole, Mr. Liſle, after obſerving farther, that, if the ground be good, and the year a feeding one, rath-ripe barley is apt to run rank, and to fall while very green in the ear, which occaſions the grain not to fill; concludes, in regard to this ſort of corn, that it ſhould always be ſown early, that the land ſhould not have a north expoſure, and that the ſoil in which it is planted ſhould be pretty good, either naturally ſuch, or rendered ſo by art; "for we know, ſays he, that the poorer the ground is, the weaker and poorer the ſtraw will be in all ſorts of corn; and if the rath-ripe barley has by nature a weaker and thinner ſtraw than the late-ripe barley, and on that account is apter to crumple, to bend down, and to break in the ſtraw before it is ripe; much more will it be apt to do ſo, when the ſtraw is made much thinner and weaker than naturally it would be, by the poverty of the ground it is ſown in. It is very evident to me, that rath-ripe barley ought not to be ſown on poor ground, and much leſs ſo in caſe it lies declivous from the ſun towards the north." *Liſle's Huſbandry, vol.* I. *p.* 273, 274.

The middle-ripe barley, as Mr. Liſle calls it, meaning the common ſpring barley, bears late ſowing, even upon ground declivous from the ſun, better than the rath-ripe ſort; but not near ſo well as the late-ripe, or common long-eared barley; nor will its ſtalk ſtand ſo long. Mr. Liſle was convinced from experience, that late-ripe barley will endure being ſowed when the ground is wetter than will do for the rath-ripe ſort, and that a bottom ground, or vale pent in between two hills, though ſhaded by one of them from the ſun, will, by means of the warmth and cloſeneſs of the air, often ripen corn as faſt as the ground that lies declivous to the ſun. In a field which he ſowed with the common ſpring barley, the loweſt part of which laid on a flat, ripened regularly, and even ſooner than another part of the ſame field which lay upon the ſide of a hill declivous to the ſun: but on that ſide of the ſame hill which ſloped from the ſun, the corn was more edge-grown, lay backward, and neither looked ſo white, nor was it ſo ripe. *Liſle's Huſbandry, vol.* I. *p.* 275.

The land which lies both very dry and healthy, and in which both mellowneſs and lightneſs are joined to a proper ſtrength of ſoil, is that which produces the beſt body, and thinneſt rinded barley; qualities which always recommend this grain, eſpecially to the maltſters. Such generally is the barley of the growth of the hilly countries. But poverty of ſoil is by no means requiſite in land, in order to its producing a plump and thin rined barley: though it is allowed, that poor land which lies dry and warm, will bear better corn of this kind, than rich land in a cold and wet ſituation: for barley does not ſtand ſo much in need of ſtrength in the land, as of the healthineſs and warmneſs of the ſoil; though both are beſt where they can be had. *Liſle's Huſb. vol.* I. *p.* 281.

With regard to the choice of ſeed-barley, it is neceſſary to obſerve, that the beſt grain for ſowing is that which is not blackiſh at the tail, nor has a deep redneſs, but is of a pale lively yellow colour, intermixed with a bright whitiſh caſt, and if the rind be a little ſhrivelled, it will be ſo much the better; for that ſlight ſhrivelling occaſioned by its having ſweated in the mow, is a ſure indication that its coat is thin. The huſk of thick rind barley being too ſtiff to ſhrink, will lie ſmooth and hollow, even when the inſide flour has ſhrunk from it.

The neceſſity of a change of ſeed from time to time, by ſowing that of the growth of a different ſoil, is no where more evident than in the culture of this grain, which otherwiſe becomes coarſer and coarſer every year. But at all times in this, as well as in all other grain, the utmoſt care ſhould be taken that the ſeed be full bodied.

Mr. Liſle tells us, that in order to be ſatisfied of this, he took out of a heap of barley ſixty grains, of different ſizes, viz. twenty of the biggeſt, twenty of the middle ſize, and twenty of the ſmalleſt corns. Twenty of each ſort of theſe grains he planted in three pots, each filled with the ſame ſort of mould, which was very rich. In eight or nine days time, thirteen of the fulleſt bodied grains were come up, nine of the middle ſized, and only five of the ſmalleſt, and the plants of the plumpeſt corn exceeded thoſe of the others, both in colour and breadth of blade. In three days after, he found nineteen blades of the largeſt ſort come up, ſeventeen of the middle ſize, and thirteen of the ſmalleſt; and in three days more, the blades of the beſt and of the middle ſort were all come up, while only ſeventeen of the worſt had ſprouted, with ſuch manifeſt diſadvantage in colour and ſtrength in theſe laſt, as plainly ſhewed that many of them would not have come up at all in poor ground. *Liſle's Huſband. vol.* I. *p.* 283.

It is natural to ſuppoſe that barley will, like wheat, be benefited by being ſteeped before it be ſown: for as rain cannot be depended upon ſoon after the ſowing of ſpring corn, there is ſurely an equal reaſon for extending the practice of theſe ſorts of grain, as well as to thoſe which are ſown in the autumn. Liming indeed may hurt barley, if hot weather ſhould ſoon follow after the ſowing, but a little ſprinkling of ſoot bids fair for improving it, at leaſt it will prevent the inſects from preying upon the ſeed.

The

The Rev. Mr. Elliot informs us, that a farmer, who was obliged to attend other buſineſs in the courſe of the morning, ſowed oats at break of day, and harrowed them in before ſun-riſing. The conſequence was, that the corn thus early ſown, out-ſtripped the other oats ſown on the ſame day after the ſun was up, had larger ears, and appeared every way better, though the ſpot in which they grew was the worſt part of the field. If the dew, when buried with the corn had this effect, it is reaſonable to ſuppoſe that a much greater would have been produced, had the ſeed been ſown in the evening, left all night to have been ſoftened with the dew, and then harrowed in, in the morning. *Elliot's Eſſay on Field Huſbandry*, *p.* 29.

Mr. Liſle alſo tells us, that a maltſter in Hampſhire having taken lands in the beginning of May, and no barley being to be had, he, by the perſuaſion of his malting-ſervant, made uſe of barley he had wetted, and was juſt well chitted or ſprouted; this corn came up well, and produced as good a crop as any ſown that year. *Liſle's Huſbandry*, *vol.* I. *p.* 284.

Barley is generally ſown either after a fallow, or on an erſh or ſecond crop. If after a fallow, the land muſt be ploughed at leaſt three times; and at the firſt ploughing, it ſhould be laid in ſmall ridges, and in that manner remain during the winter for the froſt to mellow it: but if another ploughing can be given it in January, or in the beginning of February, the ground will be ſtill much better broken and prepared. In March theſe ridges are ſplit, the ground is well harrowed, and laid as ſmooth as can be, and, if poſſible, it is ploughed again the ſame day, in order to ſow. But in ſtrong wet lands, the beſt way is to lay it round, and make deep furrows to receive the water.

Some at the time of twifallowing in June, make the land very fine, and ſow it with turneps, which they feed with ſheep in the winter; and in March they plough it up, and order it as before; but others, who take this method of ſowing turneps, give it only one ploughing in March, juſt before they ſow.

Thoſe who ſow barley upon an erſh, after wheat, plough up the wheat ſtubble in as dry weather as they can, as ſoon as the time of ſowing wheat is over, which is generally about the beginning of October, and lay three ridges into one, if they have dung to ſpread upon it: but if they have not, they plough it in ſmall ridges, as before directed, that it may be the drier, and be the better mellowed by the froſt: they then plough it up again in March, and order it as before. Some farmers injudiciouſly ſow their barley after oats, in which caſe, neither of theſe three ploughings ought by any means to be neglected; and the land will be in much better order if the firſt of them be given in October: or, if the harveſt be early, the weather dry, and the huſbandman can poſſibly find time to do it, he will improve his ground ſtill more, by ploughing it up before he ſows his wheat, juſt as harveſt is in: this will be half as good as a ſummer's fallow. But all years will not admit of this practice. *Mortimer's Huſbandry*, *vol.* I. *p.* 131.

Some ſow their barley on ſmall ridges, and others on broad lands; the latter cannot be laid too round.

Mr. Mortimer relates, that a farmer in Eſſex, who lived near a market-town, from whence he had good quantities of dung, uſed to ſow his land with barley and clover; reaped the corn at harveſt, fed the clover all the winter, and from ſpring till the middle of July, when he fallowed his ground. In the next ſpring he ſowed it again with barley and clover, and repeated every year this method, by which he had large crops. His land was a rich light mould, ſomewhat inclining to a gravelly bottom. *Mortimer's Huſbandry*, *vol.* I. *p.* 132.

A correſpondent of the editors of the *Muſeum Ruſticum*, obſerves, that a few years ago he ſowed twenty-five acres of land, in fine tilth, with broad clover and barley; but the ſpring being backward and cold, and the ſummer wet, the clover got too forward, and overpowered the barley. At harveſt they were both cut together; and the clover being full of juice, occaſioned its being a tedious time before the barley could be houſed. When he got it into the barn, the men complained much of its threſhing ſo badly, that they could not undertake to do it unleſs he would double the price to them: as this could not be afforded, he ordered them to give it only a light beating, leaving the under corn in the ſtraw, together with the clover, for the cattle.

By this means he loſt half his crop by the clover; and what barley could be obtained was lean, and thin-bodied, fetching but a very indifferent price at market.

As this was not the firſt loſs of the ſame kind he had experienced, he was determined, if poſſible, to find out ſome remedy; and accordingly applied to a very intelligent farmer in the neighbourhood, who adviſed him to ſow his clover, for the future, a month after the barley, by which means it would not prove too rank. This advice he accordingly followed, and found it anſwer extremely well; and has therefore, to his great advantage, continued the practice ever ſince. He adds, that there is no danger of the clover failing, though the ſeaſon ſhould prove dry; and that the ſeed is to be ſcattered on the ground without any farther care, there being no occaſion to harrow or roll it; for the ſmall blades of the barley will keep moiſture enough in the land to ſupply the ſmall wants of the clover during its infant growth, and when the barley is off, it will thrive ſurprizingly. *Muſeum Ruſticum*, *vol.* III. *p.* 315.

It has been already obſerved, that the uſual time of ſowing is in March, April, or the beginning of May. It is generally thought moſt adviſeable to ſow light lands the earlieſt, and to embrace the firſt dry ſeaſon that offers for doing it; dry weather being beſt for moſt ſummer corn. Clayey grounds, and lands ſubject to weeds, are thought to produce the beſt crops when ſowed late. Mr. Mortimer ſays, that barley will do well when ſown even about the middle of May, if the ſeed has been properly ſteeped. *Mortimer's Huſb. vol.* I. *p.* 132.

The common method is to ſow the barley ſeed with a broad-caſt at two ſowings; the firſt being harrowed in once, the ſecond is harrowed until the ſeed is buried; the common allowance of ſeed is four buſhels to an acre: but if the farmers could be prevailed upon to alter this practice, they would ſoon find their account in it; for if a third part of that quantity be ſown, there will be a much greater produce, and the corn will be much leſs liable to lodge, as I (ſays Mr. Miller) have many times experienced; for when corn, or any other vegetables ſtand very cloſe, the ſtalks are drawn up weak, and thence incapable of reſiſting the force of the winds, or ſupporting themſelves under heavy rains: but when they are at a proper diſtance, their ſtalks will be more than twice the ſize of the other, and therefore are ſeldom laid. I have frequently obſerved in fields where there has been a foot-path through their middle, that the corn, which has ſtood thin on each ſide of the path, hath ſtood upright, when all the reſt on both ſides has been laid

flat

flat on the ground; and whoever will give himſelf the trouble to examine theſe roots near the path, will find them tiller out (*i. e.* have a greater number of ſtalks) to more than four times the quantity of the other parts of the field. I have ſeen experiments made by ſowing barley in rows acroſs divers parts of the ſame field, and the grains ſown thin in the rows, ſo that the roots were three or four inches aſunder in the rows, and the rows a foot diſtant; the intermediate ſpaces of the ſame field were at the ſame time ſown broad-caſt in the uſual way; the ſucceſs was this: the roots which ſtood thin in the rows tillered out from ten or twelve, to upwards of thirty ſtalks on each root, the ſtalks were ſtronger, the ears longer, and the grains larger than any of thoſe ſown in the common way; and when thoſe parts of the field, where the corn was ſown in the uſual way, has been lodged, theſe parts ſown thin have ſupported their upright poſition againſt wind and rain, though the rows have been made not only lengthways, but acroſs the lands, in ſeveral poſitions; ſo that there could be no alteration in regard to the goodneſs of the land, or the ſituation of the corn: where therefore ſuch experiments have been made, and always attended with equal ſucceſs, there can be no room to doubt which of the two methods is moſt elligible, ſince if the crops were only ſuppoſed to be equal in both, the ſaving two thirds of the corn ſown is a very great advantage, and deſerves a national conſideration, as ſuch a ſaving, in ſcarce times, might be of very great benefit to the public. This ſaving of ſeed-corn muſt be underſtood to regard ſuch as is ſown broad-caſt; for if it be ſown in drills, an eighth part of the ſeed uſually ſown will be ſufficient for an acre of land, and the produce will be greater; for all ſorts of corn are naturally inclined to ſend out ſeveral ſtalks from each root, which they rarely fail to do where the roots are at a proper diſtance, and have room; nor do ſtalks grow in this caſe near ſo tall, but are much ſtronger than when they are near together, when they rarely have more than two or three ſtalks; whereas thoſe roots which have proper room, ſeldom have leſs than ten or twelve. I have had eighty ſtalks upon one root of barley, which were ſtrong, produced long ears, and the grain was better filled than any I ever ſaw grow in the common method of huſbandry, and the land on which this grew was not very rich; but I have frequently obſerved on the ſides of hot-beds in the kitchen gardens, where barley-ſtraw has been uſed for covering the beds, that ſome of the grains left in the ears have dropped out and grown, the roots have produced from thirty to ſixty ſtalks each, and thoſe have been four or five times larger than the ſtalks ever arrive at in the common way; but to this I know it will be objected, that although upon rich ground in a garden, theſe roots of corn may probably have ſo many ſtalks, yet in poor land they will not have ſuch produce; therefore unleſs a greater quantity of ſeeds be ſown, the crop will not be worth ſtanding, which is one of the greateſt fallacies that can be imagined; for to ſuppoſe that poor land can nouriſh more than twice the number of roots in the ſame ſpace as rich land, is ſuch an abſurdity, as one could hardly ſuppoſe any perſon of common underſtanding guilty of; and yet ſo it is: for the general practice is to allow a greater quantity of ſeed to poor land, than for richer ground, not conſidering that where the roots ſtand ſo cloſe, they will deprive each other of their nouriſhment, and conſequently ſtarve themſelves, which is always the caſe when the roots ſtand cloſe, which any perſon may at firſt ſight obſerve in any part of the fields where the corn happens to ſcatter when they are ſowing it; or in places where by harrowing, the ſeed is drawn in heaps, thoſe patches will ſtarve, and never grow to a third part of the ſize as the other parts of the ſame field; and yet, common as this is, it is little noticed by farmers, otherwiſe they ſurely would not continue their old cuſtom of ſowing. I have made many experiments for ſeveral years in the pooreſt land, and have always found that all crops, which were ſown or planted at a greater diſtance than uſual, have ſucceeded beſt upon ſuch land; and I am convinced if farmers could be prevailed upon to quit their prejudices, and make trial of this method of ſowing their corn thin, they would ſoon ſee the advantage of this huſbandry. *Miller's Gard. Dict.*

It is a common practice in ſome parts to ſcatter the dung of pigeons, poultry, &c. over barley and other corn, after the corn is ſown; but if this method be purſued, care ſhould be taken to ſcatter the dung immediately; becauſe then the ſhoot will eaſily make its way through: but when laid on later, it burns up, and eats the blades of the young plants. *Mortimer's Huſbandry, vol.* I. *p.* 133.

It too often happens from unfavourable weather, and an extremely dry ſpring, that it is impoſſible by the common method to break the clods, and prepare the ground ſufficiently for ſowing barley; in which caſe it has been the uſual method to break the clods with a large beetle, called, from its uſe, a clotting-beetle. But this being a very chargeable and tedious method of preparing land, induced the ingenious Mr. Randall of York, to conſtruct an inſtrument, which he calls a ſpiky roller, by the aſſiſtance of which a large quantity of land may, in ſuch a dry ſeaſon, be ſoon reduced to an exceeding fine tilth, with very little trouble. The reader will find a full account of this uſeful inſtrument, the manner of making and uſing it, together with a figure of the roller, under the article SPIKY ROLLER.

After the barley is ſown and harrowed in, the ground ſhould be rolled after the firſt ſhower of rain, to break the clods and lay the earth ſmooth; which will render it better to mow the barley, and alſo cauſe the earth to be cloſer to the roots of the corn, which will be of great ſervice to it in dry weather.

And alſo when the barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will again preſs the earth cloſe to the roots of the corn, and thereby prevent the ſun and air from penetrating the ground, which will be of ſingular ſervice in dry ſeaſons; and this rolling of it before it ſtalks, will cauſe it to tiller out into a greater number of ſtalks, ſo that if the plants ſhould be thin, this will cauſe them to ſpread ſo as to fill the ground, and likewiſe ſtrengthen the ſtalks. *Miller's Gard. Dict.*

If the corn grows too rank, as it is ſometimes thought to do in a wet ſpring, mowing is then much better than feeding it; becauſe the ſcythe takes off only the rank tops, but the ſheep feed upon all indifferenty: nor ſhould they even in any caſe be left upon it too long, becauſe being particularly fond of the ſweet end of the ſtalk next the root, they will bite ſo cloſe as to injure the future growth of the plant.

Barley is ripe when the red roan, as the farmers call it, meaning a reddiſh colour on the ear, is gone off, when the ears droop, and fall, as it were, double againſt the ſtraw, and the ſtalks have loſt their verdure. If it be full of weeds it muſt lie in the ſwarth till they are dry. It is not apt to ſhed; but in wet weather it will be apt to ſprout

ſprout or grow muſty; and therefore every fair day after rain it ſhould be ſhook up and turned; and when it is tolerably dry, let it be made up into cocks; but be ſure never to houſe it till thoroughly dry, leſt it mow-burn, which will make it malt worſe than if it had ſpired in the field. The common produce of barley is two or three quarters upon an acre. *Mortimer's Huſbandry, vol.* I. *p.* 133.

Mr. Liſle ſays, that poor thin barley and oats ſhould be cut a little ſooner than if the ſame plants were ſtrong and vigorous; for that the ſtraw, when the plants are full ripe, will not ſtand againſt the ſcythe. In this caſe the barley, in particular, muſt lie in ſwarth till it is thoroughly dry. Some of his barley, which lay out in ſwarth five or ſix days in very fine weather, though both blighted and edge-grown, grew plump, and acquired very near as good a colour as the beſt. He reckons ſhort ſcythes the beſt for mowing lodged or crumpled corn, becauſe they miſs the feweſt plants; and obſerves that a bow upon the ſcythe, which will carry the ſwarth away before it, is preferable to a cradle, the fingers of which would be pulled to pieces by the intangled corn, in drawing back the ſcythe. *Liſle's Huſbandry, vol.* I. *p.* 335.

Mr. Du Hamel tells us, that a farmer at Acou, obſerving that the chief hopes of more than common ſucceſs by means of the New Huſbandry, were founded on the frequent ſtirring of the ground while the corn was in it, and on allowing each plant ſufficient ſpace to extend its roots, and thereby collect the more nouriſhment, tried an experiment which appeared to him very proper to diſcover whether the effect would anſwer. He carefully cultivated a grain of barley, which grew by chance in his vineyard. This plant, ſaid he, ſtands diſtant from any other: it can extend its roots every way; it is in a rich ſoil, and cannot want for food: by joining frequent culture to theſe advantages, this plant of barley, according to the principles of the New Huſbandry, ought to yield a ſurprizing increaſe. His reaſoning was juſt, and the experiment confirmed it; for this ſingle grain of barley produced two hundred ears, and about thirty ſtalks which had no ears. Some of the ſtalks were four feet high, and moſt of them three. Mr. Du Hamel counted twenty-four grains in a middling ear. Thus one grain, planted in a good ſoil, and well cultivated, produced 4800 grains; and the ſtraw of this ſingle plant of barley made of itſelf a ſheaf. *Tranſlation of Du Hamel's Huſb. p.* 113.

We have already obſerved, under the article SOAP ASHES, that Sir Hugh Platt, by ſpreading that manure over his land, had a ſurprizing crop of barley, the plants of which were of a prodigious ſize. An ear of this barley is delineated in its natural ſize, Plate III. Fig. 1.

BARM, yeaſt, or the thick cruſt that riſes on the ſurface of beer, while it is fermenting.

BARN, a covered place or houſe for laying up any ſort of grain, hay, or ſtraw.

Every farm ſhould be furniſhed with barns proportioned to the quantity of corn it produces, which will be a great advantage to the farmer. The barns ſhould have a dry ſituation, and be properly placed in the farm-yard, but not quite contiguous to the houſe, for fear of fire.

A barn is uſually made of wooden frames covered with planks of oak, or built of brick or ſtone, which ever the country affords in the greater plenty; and in either caſe there ſhould be ſuch vent-holes, or openings, in its ſides or walls, as to afford free admittance to the air, in order to prevent the mouldineſs that would otherwiſe, from the leaſt dampneſs lodging in the corn. The gable ends may be always of brick or ſtone, for the ſake of greater ſolidity, and the whole may be roofed with thatch or tiles, as is moſt convenient. The ſize of the barn ſhould be proportioned to the crop uſually produced by the land to which it belongs. Two large folding doors ſhould face each other, one in each ſide of the building, for the convenience of carrying in or out a waggon-load of corn in ſheaves; and theſe doors ſhould be of the ſame breadth with the threſhing-floor to afford the more light and air; the former for the threſhers, and the latter for winnowing. Over the threſhing-floor, and a little above the reach of the flail, poles are often laid a-croſs from one beam to another, to form a kind of upper-floor, upon which the threſher may throw his ſtraw or haulm, to make an immediate clearing, till he has time to ſtow it more properly elſewhere: and on the outſide, over the great doors, it will be right to form a large penthouſe, made to project ſufficiently to cover a load of corn, in caſe a ſudden ſtorm ſhould come on before it can be houſed; and alſo to ſhelter the poultry in the farm-yard, in great heat, or bad weather.

It is moſt adviſable, and indeed moſt commonly practiſed in countries which abound in corn, to have a ſeparate barn for wheat, another for ſpring-corn, ſuch as barley and oats, and a third for peas, tares, lentils, clover, ſainfoins, &c.

Some art, which muſt be the reſult of practice, is neceſſary in placing and piling up the ſheaves in barns. But it may not be uſeleſs to obſerve, that it is always neceſſary to preſs them as cloſe to the walls of the barn as poſſible, ſo as not to afford the leaſt room for rats, or other vermin to creep in between them: for if they once get admittance they will ſoon penetrate further, lodge themſelves in the mow, and do prodigious damage to the corn. Where this misfortune happens, the only remedy is to take down the mow, kill the vermin, and pile it up a-new.

But the floor, or threſhing place, is the principal part of every barn, and therefore the greateſt care ought to be taken in making it. In order to this, the ſurface of the intended threſhing place is dug away to the depth of about ſix inches, and the earth thus taken out, after being well cleared of ſtones, is mixed with the ſtrongeſt clay that can be procured, and with the dung of cows or oxen. This mixture is then worked together with water, till it is of the conſiſtence of ſtiff mortar, and the compoſt thus made is ſpread as ſmooth as poſſible with a trowel, upon the ſpot from whence the earth was taken. As it cracks in drying, it muſt be beaten down with great force; or rolled with a heavy roller till all the crevices are filled up; and this muſt be continued till it is quite ſolid, hard, and firm.

The beſt barn-floor, both for threſhing and for keeping corn, is that which is drieſt, ſmootheſt, moſt completely ſolid, and conſequently freeſt from cracks and holes, in which inſects and vermin may ſhelter themſelves, and even breed. The ancients were remarkably careful in this reſpect, as we learn from Cato, Varro, and Columella, the laſt of which excellent huſbandman relates particularly the great pains they took, firſt to dig up the ground to ſome depth, in order to moiſten it with freſh lees of oil, but not with any that had ſalt in them; then to mix it thoroughly with chaff, and ram it down as cloſe as poſſible; afterwards as it dried, to ſtop all the cracks and crevices that appeared, to continue beating it down with great force,

to render it quite level; and, laſtly, to ſtrew it again with chaff, which they trod in, and then left it to be completely dried by the ſun. All theſe writers agree, that the lees of oil, thus uſed, prevent the growth of weeds in theſe floors, and contribute to preſerve the corn from being plundered by the mice and ants. Their barns were always ſeated high, and as dry as poſſible.

A floor made in the above manner muſt be greatly preferable to either ſtone, or the earthen floors, too common in many parts of England, and from which ſuch dampneſs has been communicated to the corn, as has rendered wheat, for example, ſixpence a buſhel the worſe, either for keeping or exporting.

Boarded threſhing-floors, made of ſound, thick, well ſeaſoned planks of oak, are exellent for ſervice, will laſt a long time, and may be converted into good floorings for rooms, by planing them down, after they are become too uneven for the purpoſe originally intended.

BARNACLES, horſe-twitchers, or brakes, are a ſort of inſtruments uſed by farriers to put upon horſes noſes, when they will not ſtand quietly, to be ſhod, blooded, or dreſſed.

There are ſeveral ſorts of barnacles, the common ſort are rollers of wood, bound together, with the horſe's noſe between them. Another ſort have handles, and are therefore termed pincers, to diſtinguiſh them from the foregoing. And a third ſort are held together at the top by a ring incloſing buttons, having the top buttons held by an iron pin riveting through them.

BARREN CORN, a name given to a diſtemper in corn, by M. Aimen, who firſt obſerved it. The ears of wheat or rye, the ſpecies moſt ſubject to this diſtemper, which are thus affected, are long, lean and white; in ſome the ſtamina, or ſmall threads in the middle of the flower, are dry, tranſparent, and horned; the female organs are ſmall, whiter, and leſs velvetty, than in healthy ears: in others, the filaments are ſwelled, the apices, or knobs on the tops of the ſtamina, void of duſt, or farina, and the ſtigmata badly unfolded. The ſtigmata of all the bloſſoms of an ear are ſomtimes dried and parched; at other times the apices are ſwelled.

M. Aimens thinks, with Theophraſtus, that theſe accidents happen to ſuch plants as grow with moſt vigour. Then, ſays he, the ſap, which is powerfully conveyed into the leaves and other parts of the plant, prevents the organs of fructification from unfolding themſelves.

He alſo imagines that froſt may cauſe this accident, by particularly affecting the female organs: and he thinks, that a hot gleam of ſun-ſhine coming after a hard ſhower may have the ſame effect. If this be the caſe, the diſtemper in queſtion may be ranked with the parched and ſhrivelled corn, or perhaps with the empty-eared corn. Laſtly, the ſame naturaliſt obſerves, that inſects are ſometimes, though very rarely, the cauſe of this diſtemper.

BARREN EARTH, a name given by ſome to the under ſtratum of earth, or that which lies below the ſtratum frequently turned up, and cultivated for the nouriſhment of plants.

This notion of the under ſtratum of earth being dead or barren, and will deſtroy every vegetable planted in it, ſeems to be founded on a miſtake; for every kind of earth, whether it be upon or under the ſurface, is certainly capable of giving nouriſhment to plants, provided it be for ſome time expoſed to the influence of the air, froſts, &c. in order to enable it to diſpenſe its nutritive qualities. An earth ſeemingly barren dug out of a deep pit, will, if ſpread on the ſurface, and properly ſtirred and expoſed, be ſoon in a condition of bearing plants, and even much more ſo than the earth, which having been long at the ſurface, is almoſt exhauſted, by the number of vegetables it has ſucceſſively nouriſhed. The notion of any earth being barren, merely becauſe it is placed at a diſtance from the ſurface, is by the moſt intelligent naturaliſts exploded: its particles may perhaps want a proper arrangement, but it always poſſeſſes the vegetative quality. This opinion has been confirmed by repeated experiments; and a very remarkable one of this kind is related by a correſpondent of the editors of the *Muſeum Ruſticum*, *vol.* I. *p.* 100, &c. where the writer tells us, that he planted a quantity of potatoes in a piece of what they called dead barren earth, the upper bed having been taken away and ſpread on the adjacent land. Yet in this ſpot of ground dug two ſpits deep by the help of ſpades and mattocks, and the earth broke as fine as poſſible, he had a prodigious crop of remarkably fine potatoes; though the earth had not been expoſed to the influence of the atmoſphere above two months, it being dug in February, and the potatoes planted the latter end of March.

BARREN SPRINGS, a name given by huſbandmen to ſuch ſprings whoſe waters are injurious to land.

Moſt waters that flow from coal mines, or through beds of ſulphureous minerals, have this pernicious quality, deſtroying vegetables, inſtead of nouriſhing them. They have a harſh and brackiſh taſte, are generally of a reddiſh colour, and depoſit a reddiſh ſediment in the channel through which they flow. They are much better when they have run ſome diſtance, than at their firſt breaking out on the ſurface of the earth. *Mortimer's Huſbandry*, *vol.* I. *p.* 20.

BARS, the fleſhy rows that run a-croſs a horſe's mouth, reaching almoſt to the palate. They are very diſtinguiſhable in young horſes.

BARTH, a warm place, or paſture, for calves or lambs.

BARTON, *or* BARKEN, the yard of a houſe.

BASTARD *Alkanet*, called alſo *baſtard gromill*, or *ſalfarn*, a weed common among corn, eſpecially rye. It may be eaſily known by its red roots, which yield a red tincture, and are uſed by the young girls in Sweden to colour their cheeks. From the root uſually riſes a ſingle ſtem about a foot high, rough, and branching out at the top. The flowers are ſmall and white, ſurrounded with five long, narrow, hairy leaves, forming what the botaniſts call the empalement of the flower cup, and ſucceeded by four white rough ſeeds. *See a figure of this plant on* Plate III. Fig. 2

BAVINS, bruſh-faggots, or faggots made with the bruſh-wood at length.

BAUSON, the ſame with badger. *See* BADGER.

BAY, a colour in horſes, ſo called from its reſembling the colour of a dried bay-leaf.

There are various degrees of this colour from the lighteſt bay to the dark, which approaches nearly to the brown, but is always more gay and ſhining. The bright bay is an exceeding beautiful colour, becauſe a bright bay horſe has generally a reddiſh daſh, with a gilded aſpect, his main and tail black, with a black or dark liſt down his back. The middle colours of bay have alſo frequently the black liſt, with back main and tail. And the dark bays have almoſt always their knees and paſterns black; and we meet with ſeveral

ſorts of bays, that have their whole limbs black from their knees and hocks downwards. The bays that have no liſt on their backs, are, for the moſt part, black over their reins, which goes off by an imperceptible gradation from dark to light towards the belly and flanks. Some of theſe incline to a brown, and are more or leſs dappled. The bay is one of the beſt colours, and horſes of all the different kinds of bays are commonly good, unleſs when accidents happen to ſpoil them while they are colts. *Gibſon on Horſes, vol.* I. *pag.* 44.

BAY *of a barn*, that part where the mow is placed. Hence ſuch barns as have the threſhing-floor in the middle, and a ſpace for a mow on each ſide, are called barns of two bays, &c.

BAYARD, a bay horſe.

BAY-SALT, is ſalt made from ſea-water by the heat of the ſun only, without the aſſiſtance of fire. The cryſtals of this ſalt are much larger than thoſe of the common ſalt, occaſioned by the gentle evaporation of the watery particles; whence the cryſtals have a ſufficient time to ſhoot, which they have not in the common method. From this circumſtance bay-ſalt becomes much better for ſalting meat, &c. than the common.

BEANS, a ſort of pulſe well known, and of which there are two ſpecies, diſtinguiſhed by the names of the garden-bean, and the horſe-bean.

Some few trials have been lately made in France to raiſe garden beans in open fields, on the principles of the new huſbandry; and the reſult of theſe experiments ſufficiently indicate that very large crops may be procured by that method, if properly practiſed. M. Du Hamel tells us, that M. Eyma planted, in December 1755, in a field near Bourdeaux, the common ſort of garden beans, in a middling ſoil not dunged, but thoroughly ploughed a foot deep. The rows were two feet aſunder, and the plants a foot diſtant from one another. Theſe beans, which every one thought too thinly ſown, being aſſiſted by frequent hoeings, yielded a greater crop than any in the common way. When they begin to ripen, M. Eyma gave the ſpaces between them a good ploughing, and on the twenty-third of June ſowed in each of them a row of red kidney-beans, which came up very well. In a fortnight after he plucked up the garden beans, and gave the ground on which they ſtood a ſlight hoeing. Theſe kidney-beans proved the fineſt he ever ſaw. He repeated the ſame experiment in 1756, and was rewarded with ſuch ſucceſs as ſurpaſſed his warmeſt expectations. *Traité de la Culture des Terres, tom.* V. *page* 81.

Horſe BEANS, delight in a ſtrong moiſt ſoil, and an open expoſure, for they never thive well on dry warm land, or in ſmall incloſures, where they muſt, and are frequently attacked by the black dolphin fly: theſe inſects are often in ſuch quantities as to cover the ſtems of the beans entirely, eſpecially all the upper part of them; and whenever this happens, the beans ſeldom come to good; but in open fields where the ſoil is ſtrong, and the plants have room, this rarely happens.

Theſe beans are uſually ſown on land which is freſh broken up, becauſe they are of uſe to break and pulveriſe the ground, as alſo to deſtroy weeds; ſo that the land is rendered much better for corn, after a crop of beans, than it would have been before, eſpecially if they are ſown and managed according to the new huſbandry, with a drill plough, and the horſe-hoe uſed to ſtir the ground between the rows of beans, which will prevent the growth of weeds, and pulverize the ground, whereby a much greater crop of beans may, with more certainty, be expected, and the land will be better prepared for whatever crop it is deſigned for after.

The ſeaſon for ſowing beans is from the middle of February to the end of March, according to the nature of the ſoil; the ſtrongeſt wet ſoil ſhould always be laſt ſown. The uſual quantity of beans ſown on an acre of land, is about three buſhels, tho' this is double the quantity that need be ſown, eſpecially according to the new huſbandry; but it will be neceſſary firſt to ſet down the practice according to the old huſbandry, and then give directions for their management according to the new. The method of ſowing is after the plough, in the bottom of the furrows; but then the furrows ſhould not be more than five, or, at moſt, ſix inches deep. If the land be newly broken up, it is uſual to plough it early in the autumn, and let it lie in ridges till after Chriſtmas; then to plough it in ſmall furrows, and lay the ground very ſmooth. Theſe two ploughings will break the ground fine enough for beans, and the third ploughing is to ſow the beans, when the furrows ſhould be made ſhallow, as before mentioned

Moſt people ſet their beans too cloſe; for as ſome lay the beans in the furrows after the plough, and others lay them before the plough, and plough them in; ſo by both methods the beans are as cloſe as the furrows are made, which is much too near; for when they are on ſtrong good land, they are generally drawn up to a very great height, and are not ſo apt to pod as when they have more room, and are of a lower growth. The better way, therefore, is to make the furrows three feet aſunder or more, which will cauſe them to branch out into many ſtalks, and bear in greater plenty than when they are cloſer; by this method leſs than half the quantity of beans will be ſufficient for an acre of land, and the air being admitted between the rows, the beans will ripen much earlier, and more equally than in the common way. *Miller's Gard. Dict.*

It has been already obſerved, that the black dolphin fly often deſtroys a crop of beans, and to prevent which, a correſpondent of the editors of the *Muſeum Ruſticum* propoſes, that when theſe deſtructive inſects are firſt ſeen on the tops of the beans, one or more perſons, provided each with a ſcymeter or hanger, ſhould be ſent in the field, and ſtrike off the heads of the beans. He adds, that by this means a crop has been often ſaved, this fly being ſeldom known to riſe again when it once falls with the bean-top to the ground. *Muſeum Ruſticum, vol.* III. *pag.* 233.

Another correſpondent in the above work ſays, that as ſoon as the beans have got ſix leaves, the ſheep ſhould be turned in to feed among them; for they will eat up all the young weeds, even the melilot, without touching the beans. He adds, that the ſheep may be kept every day among the beans till they are in bloſſom; but they muſt not be ſuffered to lie down. *Muſeum Ruſticum, vol.* III. *pag.* 339.

When beans are intended to be planted according to the new huſbandry, the ground ſhould be four times ploughed before the beans are ſet, which will break the clods, and render it much better for planting. Then uſe a drill plough, to which a hopper is fixed for ſetting the

the beans, the drills ſhould be made at three feet aſunder, and the ſpring of the hopper ſet ſo as to ſcatter the beans at three inches diſtant in the drills. By this method leſs than one buſhel of ſeed will plant an acre of land. When the beans are up, if the ground be ſtirred between the rows with a horſe-plough, it will deſtroy all the young weeds; and when the beans are advanced about three or four inches high, the ground ſhould be again ploughed between the rows, and the earth laid up to the beans; and if a third ploughing, about five or ſix weeks after be given, the ground will be kept clean from weeds, and the beans will ſtalk out, and produce a much greater crop than in the common way. *Miller's Gard. Dict.*

A correſpondent of the editors of the *Muſeum Ruſticum*, has given the following method of cultivating beans in the vale of Ayleſbury.

"Firſt, ſays he, I plough two furrows on each outſide of the land, but ſow no beans in them: I afterwards drill, with an inſtrument hereafter deſcribed, the three next furrows: then I plough two furrows without drilling any beans in them, and ſo on, ſowing three, and leaving two for intervals, till the land is finiſhed.

"When the beans are about two or three inches high, I plough two furrows up each interval, turning the furrows from the beans, ſo as to make a ridge in the middle of each interval. I have a little plough on purpoſe for this uſe, about half the ſize of a common plough, which is drawn by one horſe.

"This work ſhould be done after a rain. This year, 1764, on the fifteenth of May we had rain. I therefore went to plough in the intervals on the eighteenth, and continued at plough till all were finiſhed. On the eighth of June we had rain again. On the ninth of June I went to harrow the intervals with the triangular harrow hereafter deſcribed. About a week after that we had more rain. I then went to harrow again, going up the interval I went down before, and down that which I went up. This is what we call croſs-tining. Thus my land is laid quite ſmooth, kept clear from weeds, and the beans have a fine looſe mould to ſtrike their fibres into; and it is by far the cheapeſt way of weeding beans.

Proportions of the above DRILL (ſee Plate III. Fig. 3.)

"Diameter of the iron wheel twenty inches.

"Length of the box from A to B, twenty inches.

"Breadth of the box from B to C, ten inches.

"Depth of the box from C to D, five inches and a half.

"Diameter of the cylinder of wood upon the iron axis of the wheel, four inches. This cylinder turns out the beans regularly.

"Length of the cylinder two inches and a half. On this cylinder are twenty-one holes, a quarter of an inch deep, and half an inch in diameter.

"E is a tongue, which drops upon the cylinder, and plays up eaſily: the tongue is half an inch thick, and three quarters wide. When a larger bean than ordinary comes, it will throw the tongue up, which naturally recovers its place again; and ſo the work goes on well and even. The tongue is repreſented ſeparately with its notch at E: the notch does not go quite through it; it falls exactly on the holes of the cylinder.

"A lid takes off to put the beans into the box, and buttons down at F."

The triangular HARROW *deſcribed* (ſee Plate III. Fig. 4.)

"From A to B eighteen inches.

"The tines are nine inches a-part.

"The three tines in the croſs-bar are only three inches and a half a-part.

"E, a cock which plays upon a pin, in which are three holes to hang the whipple tree in. If you put it into the upper hole the tines bear very heavy upon the ground: I generally uſe the middle hole." *Muſeum Ruſticum, vol.* III. *pag.* 26.

When the beans are ripe they are reaped with a hook, as is generally practiſed for peaſe; and after having lain a few days on the ground, they are turned, and this muſt be repeated ſeveral times, until they are dry enough to ſtack; but the beſt method is to tie them in ſmall bundles, and ſet them upright; for then they will not be in ſo much danger to ſuffer by wet, as when they lie on the ground; and they will be more handy to carry and ſtack, than if they were looſe.

The common produce is from twenty to twenty-five buſhels on an acre of land. *Miller's Gard. Dict.*

In the ſtiff, ſtrong land, of the vale of Ayleſbury, they annually ſow a great many acres of horſe-beans, all which they uſually mow with a bare ſcythe, in ſwarth, as they call it; that is, they mow beans towards the beans; and each mower has a boy, who follows him with a fork, and lays the beans in wads. Their reaſon for mowing them in ſwarth, is on account of the largeneſs of their crops, and the beans leaning inwards: it is only when they have a thin crop, that they venture to mow them againſt their bending (this they call throating;) for ſhould they do it in common, it would break the hearts of the mowers, being as hard work again as the other.

When they mow in ſwarth, the workmen always keep the points of their ſcythes downwards, or they would ſtrip off great quantities of the beans.

In Hertfordſhire alſo, ſome farmers mow their beans with a ſcythe, and a three ribbed ſtrong cradle: this cuts a great deal in a day, lays the beans in regular rows, and ſaves the expence of a wadder; but in Buckinghamſhire they cannot uſe a cradle, their crops being in general ſo heavy, that the workmen could not carry over the ſwarth. *Muſeum Ruſticum, vol.* I. *pag.* 275.

The beans ſhould lie in the mow to ſweat, before they are threſhed out; for as the haulm is very large, and ſucculent, ſo it is very apt to give and grow moiſt; but there is no danger of the beans receiving damage, if they are ſtacked tolerably dry; becauſe the pods will preſerve the beans from injury; and they will be much eaſier to threſh after they have ſweat in the mow than before; and after they have once ſweated and are dry again, they never after give.

By the new huſbandry the produce has exceeded that of the old by more than ten buſhels an acre; for if the beans cultivated in the common method are obſerved when they are in pod, it will be found that more than half way of their ſtems have no beans on them; for by ſtanding cloſe, they are drawn up very tall, ſo the tops of the ſtalks only produce, and all the lower part is

naked; whereas in the new method, they bear almoſt to the ground; and as the joints of the ſtems are ſhorter, ſo the beans grow cloſer together. *Miller's Gard. Dict.*

Beans are a part of the diet of horſes, but chiefly uſed in mixture with bran or chaff, and by ſome upon the road, with oats; but they are moſtly given to coach-horſes and others that are conſtantly in draught. They afford the ſtrongeſt nouriſhment of all other grain, and will enable horſes to go through a great deal of heavy labour; but in ſome ſeaſons they breed a kind of vermin, which the farmers call a red bug, and is reckoned dangerous, and therefore the beſt way at ſuch times is to have them well dried and ſplit, which may, in ſome meaſure, deſtroy the malignity that is engendered in them. *Gibſon on Horſes, vol.* I. *pag.* 171.

Whoever has frequented the corn markets in London cannot but know that old horſe-beans ſell from ten to fifteen, and even more, per cent. dearer than new corn: becauſe new beans will, by their abundant crudity, give a horſe the gripes, and other diſorders equally fatal. To prevent ſuch conſequences, and at the ſame time ſave the difference between the expence of old and new corn, a correſpondent of the editors of the *Muſeum Ruſticum* tells us that he made the following experiment.

He purchaſed a quantity of new beans, and filled a large tub with them, pumping in as much water as was neceſſary to wet them: after ſoaking about ten hours he drew off the water, and laid the beans in a heap on the floor. In this manner he ſuffered them to continue till they began to heat, when he ſpread them out thinner, moving them often with a malt ſhovel, and letting them lie in beds till the germ ſwelled and became turgid. Then he carried them to a malt-kiln, and dried them gradually; and gave part of them to his horſes, as ſoon as cold.

By this preparation he aſſures us new beans will agree as well with cattle as any old corn that can be procured at the market.

The greateſt nicety in the operation is to prevent the beans from ſprouting, or malting, which would injure them, and not to dry them by too quick a heat. *Muſeum Ruſticum, vol.* I. *pag.* 327.

BEAR, or *bere*, a ſpecies of barley, called alſo winter barley, ſquare barley, and big.

This grain is chiefly cultivated in Scotland, the northern parts of England, and Ireland. It yields a very large return, but is not eſteemed ſo good for malting as the common barley, for which reaſon it is very little cultivated in the ſouthern parts of England. *See* BARLEY.

BEARD, the ſame with awm. *See* AWMS.

BEARD *of a horſe*, a name given to the hairs ſcattered on his under lip to the place where the curb of the bridle reſts.

BEARDED *oat graſs*, the ſame with wild oats. *See the article Wild* OATS.

BEAR's EAR, the Engliſh name for the plant generally called auricula.

BEC, a ſmall brook, a rivulet, a little ſtream of water.

BEDS, a name given by many writers on the new huſbandry to the ſpaces occupied by the rows of corn; to diſtinguiſh them from the intervals, or open ſpaces between theſe beds, which they term alleys. *See* ALLEY.

Yellow ladies BEDSTRAW, *cheeſe-rennet, mother-hair*, or *petty mugwort*, a weed very common in moiſt meadows and paſture grounds. Its ſlender ſtalks riſe to about a foot in height. The leaves come out in whorls, eight or nine together. They are long, narrow, and of a green colour. Two little branches generally come out near the top of the ſtalk, ſupporting a conſiderable number of ſmall yellow flowers, conſiſting of one petal, divided into four parts, and ſucceeded by two large kidney ſhaped ſeeds.

BEE, a ſmall and well known inſect, famous for its induſtry.

This uſeful and laborious inſect is divided by two ligaments into three parts or portions, the head, the breaſt, and the belly. The head is armed with two jaws and a trunk; the former of which play like two jaws opening and ſhutting to the right and left. The trunk is long and taper, and, at the ſame time, extremely pliant and flexible, being deſtined by nature for the inſect to probe to the bottom of the flowers through all the impediments of their chives and foliage; and drain them of their treaſured ſweets: but were this trunk to be always extended, it would prove incommodious, and be liable to be injured by a thouſand accidents, it is therefore of ſuch a ſtructure, that, after the performance of its neceſſary functions, it may be contracted, or rather folded up; and beſides this, it is fortified againſt all injuries by four ſtrong ſcales, two of which cloſely ſheathe it, and the two others, whoſe cavities and dimenſions are larger, encompaſs the whole. From the middle part or breaſt of the bee grow the legs, which are ſix in number: and at the extremity of the paws are two little hooks, diſcernible by the microſcope, which appear like ſickles, with their points oppoſite to each other. The wings are four, two greater and two ſmaller, which not only ſerve to tranſport them through the air, but, by the noiſe they make, to give notice of their departure and arrival, and to animate them mutually to their ſeveral labours. The hairs with which the whole body is covered, are of ſingular uſe in retaining the ſmall duſt that falls from the chives of the flowers, of which the wax is formed, as will be obſerved hereafter. The belly of the bee conſiſts of ſix rings, which ſlide over one another, and may therefore be lengthened or contracted at pleaſure; and the inſide of this part of the body contains the inteſtines, the bag of honey, the bag of poiſon, and the ſting. The office of the inteſtines is the ſame as in other animals. The bag of honey is tranſparent as cryſtal, containing the ſweet juices extracted from flowers, which the bee diſcharges into the cells of the magazine for the ſupport of the community in winter. The bag of poiſon hangs at the root of the ſting, through the cavity of which, as through a pipe, the bee ejects ſome drops of this venomous liquor into the wound, and ſo renders the pain more exceſſive. The mechaniſm of the ſting is admirable, being compoſed of two darts, incloſed within a ſheath that tapers into a fine point, near which is an opening to let out the poiſon. The two darts are ejected through another aperture, which, being armed with ſeveral ſharp beards like thoſe of fiſh-hooks, are not eaſily drawn back again by the bee; and indeed ſhe never diſengages them if the wounded party happens to ſtart and put her into confuſion; but if one can have patience to continue calm and unmoved, ſhe clinches thoſe lateral points round the ſhaft of the dart,

dart, by which means ſhe recovers her weapons, and gives leſs pain to the perſon ſtung. The liquor which at the ſame time ſhe infuſes into the wound, cauſes a fermentation, attended with a ſwelling, which continues ſeveral days; but that may be prevented by immediately pulling out the ſting, and enlarging the puncture, to let the venomous matter have room to eſcape.

Let us now conſider the generation, polity, and labours of theſe inſects, the true knowledge of which is very much owing to the modern invention of glaſs-hives, through which all the ſecrets of the community are laid open to a curious obſerver. Any perſon who carefully examines a hive at different ſeaſons of the year, will diſtinguiſh three ſorts of bees; of which the far greater number are the common working bees, who do all the buſineſs of the hive, and ſeem to be neither male nor female. The working bee is repreſented at C (Plate III. Fig. 5.) The ſecond ſort, called drones, are the males, and ſomewhat larger than the former (as A, Fig. 6.) they have no ſting, nor even ſtir from the hive, but live upon the honey prepared by the others. The third ſort is a much larger and longer bodied bee, of which there are often but one in every ſwarm or colony of young bees, who are from time to time detached from the hive in ſearch of another habitation. This large bee is what the ancients called the king, from the reſpect they always ſaw paid to it by the other bees; but being the female, the moderns more properly give the title of queen, or mother of the ſwarm. *See* Plate III. Fig. 7. B.

When theſe induſtrious inſects begin their works, it is obſerved they divide themſelves into four parties, one of which is deſtined to the fields to provide materials for the ſtructure; the ſecond works upon thoſe materials, and forms them into a rough ſketch of the dimenſions and partitions of the cells; the third examines and adjuſts the angles, removes the ſuperfluous wax, poliſhes the work, and gives it its neceſſary perfection; and the fourth is employed in bringing proviſions to the labourers that build them, becauſe poliſhing is not ſo laborious. They begin their work at the top of the hive, continuing downwards to the bottom, and from one ſide to another; and to make it the more ſolid they uſe a ſort of tempered wax, reſembling glue. The form of the cells of the honey-comb is hexagonal, which figure, beſides what is common with a ſquare and equilateral triangle, has the advantage of including a greater ſpace within the ſame ſurface.

The expedition of the bees in their labour, is almoſt incredible; for notwithſtanding the elegance and juſt proportions of the work, they are ſo indefatigable, that they will, in one day, finiſh a honey-comb a foot long, and ſix inches broad, capable of receiving three thouſand bees.

It is not eaſy to know, particularly, the manner in which they employ themſelves at this work, on account of the number of bees then in motion, by which means the eye can hardly diſtinguiſh any thing but confuſion. We have however been able to obſerve the following particulars: ſome bees, bearing in each of their talons a little piece of wax, are ſeen running to the places where their companions are at work upon the combs; at their arrival they faſten the wax to the work by means of the ſame talons, which they apply ſometimes to the right, and ſometimes to the left. Each bee is employed but a ſhort time on this work, when another takes its place.

While a part of the bees are at work in conſtructing the cells, others are employed in perfecting thoſe that are newly modelled, finiſhing the angles, ſides, and baſes, in ſo exquiſite a manner, and with ſuch remarkable delicacy, that three or four of theſe ſides laid upon one another, are not thicker than a leaf of common paper; and becauſe the entrance of the cell, which is adapted to the ſize of the bee, would on account of this delicacy, be ſubject to break, they ſtrengthen the entrance of each cell with a border of wax.

We have already obſerved, that the bees which build the cells work but a little while at a time; but it is different with regard to thoſe that poliſh them, for they work for a long while, and with great expedition, never intermitting their labour, unleſs it be to carry out of the cell the particles of wax taken off in poliſhing: and, to prevent this wax from being loſt, other bees ſtand ready to receive it from the poliſhers, and carry it to ſome other part, in order to its being employed.

Each comb has two rows of cells oppoſite to each other, which have their common baſes. The thickneſs of each comb is ſomething leſs than an inch; and, conſequently, the depth of each cell about five lines; but at the ſame time the breadth of each is little more than two.

All the combs are conſtructed with cells of this ſize, except a ſmall number of others in ſome particular parts of the hive, which are larger and appropriated to the lodging eggs, that afterwards become drones, or male bees.

There are alſo, in ſome parts of the hive, three or four cells bigger than the others, and conſtructed in a different manner. They are of a ſpheroidical figure, open in the inferior part, and attached to the extremities of the combs.

When the cells are completed, the queen takes poſſeſſion of thoſe ſhe likes beſt to depoſite her eggs in, and the reſt are left to be filled with honey. She lays one egg in each cell, and ſometimes more than an hundred of thoſe eggs in a day; but what is ſtill more remarkable, ſhe lays thoſe eggs which are to produce common bees in cells of the common ſhape and ſize, thoſe that are to become drones or males, in the cells of a larger ſize, and depoſites thoſe which are to become females, like herſelf, in the ſpheroidical cells already deſcribed.

Theſe eggs, after lying ſome time in the cells, are hatched into maggots, and fed with honey ten or twelve days, after which the other bees cloſe up the cells with a thin piece of wax; and under this covering they become gradually transformed into bees, in the manner as ſilk-worms are into butterflies. Having undergone this change, the young bees pierce through their waxen doors, wipe off the humidity from their little wings, take their flight into the fields, rob the flowers of their ſweets, and are perfectly acquainted with every neceſſary circumſtance of their future conduct. As to the males or drones, which are deſtined only to propagate their ſpecies, they live very comfortably for about three months after they are hatched; but when that time is over, and the females are impregnated, the common bees either kill them, or drive them from the hive, as burthenſome to the community, and not a drone is to be found till the next ſeaſon.

The

The method in which the bees collect their wax and honey deſerves to be a little explained. At the bottom of all flowers there are certain glands which contain more or leſs honey, that is, the moſt exalted particles of the ſugary juices of the plant. Theſe juices the bee ſucks up with her proboſcis or trunk above-mentioned, and draws it into her mouth; and when it has thus taken a ſufficient quantity into her ſtomach, returns to the hive, and diſcharges the honey into the common magazine.

When the cells prepared to receive it are full, the bees cloſe up ſome with wax till they have occaſion for the honey; the reſt they leave open, to which all the members of the ſociety reſort, and take their repaſt with a very inſtructive moderation.

It is an excellent obſervation of a modern author, that the hive is a ſchool to which numbers of people ought to be ſent; prudence, induſtry, benevolence, public ſpiritedneſs, œconomy, neatneſs, and temperance, are all viſible among the bees. Theſe little animals are actuated by a ſocial ſpirit, which forms them into a body politic, intimately united, and perfectly happy. They all labour for the general advantage; they are all ſubmiſſive to the laws and regulations of the community: having no particular intereſt, no diſtinction but thoſe which nature or the neceſſities of their young have introduced amongſt them. We never ſee them diſſatisfied with their condition, or inclinable to abandon the hive in diſguſt, or find themſelves ſlaves or neceſſitous: on the contrary, they think themſelves in perfect freedom, and perfect affluence; and ſuch indeed is their real condition. They are free, becauſe they only depend on the laws; they are happy, becauſe the concurrence of their ſeveral labours inevitably produces abundance, which contributes to the riches of each individual. Let us compare human ſocieties with this, and they will appear altogether monſtrous. Neceſſity, reaſon, and philoſophy, have eſtabliſhed them for the commendable purpoſes of mutual aid and benefits: but a ſpirit of ſelfiſhneſs deſtroys all; and one half of mankind, to load themſelves with ſuperfluities, leave the other deſtitute of common neceſſaries.

Wax is compoſed of the farina, or duſt, formed on the apices of flowers. This the bees collect, and with their fore-feet and jaws, roll up into little balls, which they convey, one at a time, to the feet of their middle legs, and from thence to the middle joints of their hind legs, where there is a ſmall cavity like a ſpoon to receive it. Theſe balls are not, however, true wax, but the ſubſtance or baſis of it: to reduce this crude ſubſtance into wax, it muſt firſt be digeſted in the body of the bee.

After the bees have brought home this crude ſubſtance, they eat it by degrees; or, at other times, three or four bees come and eaſe the loaded bee by eating each of them a ſhare, the loaded bee giving them a hint ſo to do. Hunger is not the motive of their thus eating the balls of waxy matter, eſpecially when a ſwarm is firſt hived; but it is their deſire to provide a ſpeedy ſupply of real wax for making their combs. At other times, when there is no immediate want of wax, the bees lay this matter up in repoſitories, to keep it in ſtore.

When this waxy matter is ſwallowed, it is, by the digeſtive powers of the bee, converted into real wax, which the bees again diſgorge as they work it up into combs; for it is only while thus ſoft and pliant from the ſtomach that they can fabricate it properly. That the wax thus employed is taken from their ſtomachs, appears from their making a conſiderable quantity of comb ſoon after they are hived, and even on any tree or ſhrub where they have reſted but a ſhort while before their being hived, though no balls were viſible on their legs, excepting thoſe of a few which may be juſt returned from the field.

Bees collect crude wax alſo for food; for if this was not the caſe, there would be no want of wax after the combs are made: but they are obſerved, even in old hives, to return in great numbers loaded with ſuch matter, which is depoſited in particular cells, and is known by the name of *bee-bread*. We may gueſs that they conſume a great deal of this ſubſtance in food, by the quantity collected, which, by computation, may in ſome hives amount to an hundred weight in a ſeaſon, whilſt the real wax in ſuch an hive does not perhaps exceed two pounds.

But beſides the three ſubſtances, honey, wax, and bee-bread, already mentioned, there is another with which the bees cloſe every crevice in their hives, and which is called propolis. It is a kind of reſin eaſy to be rolled out, much more tenacious than wax, and more eaſily fixed. It does not ſeem to require any preparation, being a real reſin, which they collect from trees, and employ as they find it. It grows very hard in the hive, but may be ſoftened by heat. It is diſſoluble in ſpirit of wine. It commonly diffuſes a very agreeable ſmell when heated. Its outward colour is of a reddiſh brown; its inſide reſembles wax, and is a little yelloviſh. When the bees make uſe of it, it is ſoft and pliable; but it hardens daily, and becomes in time harder than wax. This propolis ſerves alſo for another purpoſe, which is, that when a ſnail, ſlug, or any other creature too large to be carried out by the bees, has been ſlain in the hive, they caſe it over with this ſubſtance, and thereby prevent the bad effects of the putrid ſmell ariſing from dead bodies.

When the hive is become too much crowded, by the addition of the young brood, a part of the bees think of finding themſelves a more commodious habitation, and with that view ſingle out the moſt forward of the young queens. A new ſwarm is therefore conſtantly compoſed of one queen at leaſt, and of ſeveral thouſand working bees, as well as of ſome hundreds of drones. The working bees are ſome old, ſome young.

Scarce has the colony arrived at its new habitation, when the working bees labour with the utmoſt diligence, to procure materials for food and building. Their principal aim is not only to have cells in which they may depoſit their honey; a ſtronger motive ſeems to animate them. They ſeem to know that their queen is in haſte to lay her eggs. Their induſtry is ſuch, that in twenty-four hours they will have made combs twenty inches long, and wide in proportion. They make more wax during their firſt fortnight, if the ſeaſon is favourable, than they do during all the reſt of the year. Other bees are at the ſame time buſy in ſtopping all the holes and crevices they find in their new hive, in order to guard againſt the entrance of inſects which covet their honey, their wax, or themſelves; and alſo to exclude the cold air; for it is indiſpenſibly neceſſary that they be lodged warm.

When

When the bees firſt ſettle in ſwarming, indeed when they at any time reſt themſelves, there is ſomething very particular in their method of taking their repoſe. It is done, by collecting themſelves in a heap, and hanging to each other by their feet. They ſometimes extend theſe heaps to a conſiderable length. It would ſeem probable to us, that the bees from which the others hang, muſt have a conſiderable weight ſuſpended to them. All that can be ſaid is, that the bees muſt find this to be a ſituation agreeable to themſelves. They may perhaps have a method of diſtending themſelves with air, thereby to leſſen their ſpecific gravity; in the ſame manner as fiſhes do, in order to alter their gravity, compared with water.

When a ſwarm divides into two or more bands, which ſettle ſeparately, this diviſion is a ſure ſign that there are two or more queens among them. One of theſe cluſters is generally larger than the other. The bees of the ſmaller cluſter, or cluſters, detach themſelves by little and little, till at laſt the whole, together with the queen, or queens, unite with the larger cluſter. As ſoon as the bees are hived and ſettled, the ſupernumerary queen, or queens, muſt be ſacrificed to the peace and tranquility of the hive. This execution generally raiſes a conſiderable commotion in the hive, and ſeveral other bees, as well as the queen or queens, loſe their lives. Their bodies may be obſerved on the ground, near the hive. The queen that is choſen is of a more reddiſh colour than thoſe which are deſtroyed; ſo that fruitfulneſs ſeems to be a great motive of preference in bees; for the nearer they are to the time of laying their eggs, the bigger, larger, and more ſhining are their bodies.

For three or four nights before a ſwarm ſallies forth, there is in the hive a peculiar humming noiſe, of which authors give very different deſcriptions, probably owing to the ſtrength of imagination in each. Every ſound among bees ariſes from their ſtriking their wings againſt the air: their wings being their ſole organ of ſound, if we may be allowed the expreſſion. By moving their wings more or leſs forcibly and ſwiftly, they beat the air, and form the varied confuſed ſounds which we call humming. The noiſe which foretels their ſwarming is eaſily diſtinguiſhed by thoſe who are accuſtomed to it, and is more eſpecially obſerved before the caſts, or ſecond and following ſwarms. The hive appears ſo full of bees, that part of them hang in cluſters on the outſide; and the drones are perceived flying about in greater numbers than uſual. But the moſt certain ſign, and which indicates this event to be on that day, is, that the bees refrain from flying into the fields, though the ſeaſon ſeems inviting. Juſt before they take their flight, there is an uncommon ſilence in the hive, and this continues for ſome time: but as ſoon as one breaks forth, they all follow, and are inſtantly on the wing. They ſeldom ſwarm before the ſun has warmed the air; that is, not before ten in the morning, and ſeldom later than three in the afternoon; and the time of the year in which they moſt generally ſwarm, is from the middle of May to the end of June: but ſometimes ſooner or later, according as the ſeaſon is more or leſs favourable. The earlieſt ſwarms do not always prove the beſt, eſpecially if they are ſo early as the end of April or beginning of May: for the weather often is afterwards ſo wet and cold, that they are frequently in danger of being deſtroyed, or greatly reduced, by famine. Though ſwarms which iſſue forth ſo late as July are not in danger of a preſent famine; yet, they ſcarcely have time and opportunity to lay in a ſufficient ſtore for the winter. Towards the ſeaſon of ſwarming, the door of the hive ſhould be enlarged, to give the bees the greater freedom to iſſue out; and it ſhould likewiſe remain ſo for young ſwarms, during the firſt fortnight or three weeks, to allow the freer entrance to the bees, at that time extremely buſy in collecting their neceſſary ſtores. The entrance ſhould afterwards be gradually leſſened, to prevent the otherwiſe eaſy acceſs of enemies, of which there is great danger, eſpecially as the autumn advances.

Hives continue ſometimes to ſend forth ſwarms till the old hive becomes too much weakened, and part of it is empty. It is probable, that the prolific young queens prompt the bees to ſwarm thus frequently: for it is certain that if there is not a young mother qualified to bring forth a numerous progeny, though there be ever ſo great a number of bees, they will all remain, and die rather than quit the hive.

Whenever the bees of a ſwarm fly too high, they are made to deſcend lower, and diſpoſed to ſettle, by throwing among them handfuls of ſand or duſt: probably the bees miſtake this for rain. It is uſual at the ſame time to beat on a kettle or frying-pan; perhaps from its being obſerved that the noiſe of thunder prompts ſuch bees as are in the field to return home. Precautions of this kind are the more neceſſary, if, as Dr. Warder, in his 'True Amazons, obſerves, "the bees always provide a place for their habitation before they ſwarm; either in ſome hollow tree, or in the hollow part of ſome old building, or in ſome deſerted hive, which the ſwarm have already prepared, by cleaning out whatever may be offenſive to their cleanly nature." Of this he gives an inſtance; and concludes, that "though they provide themſelves with a houſe before they ſwarm, and take much pains about it; yet if you are early enough in your taking the ſwarm, and they find themſelves at unawares in a convenient houſe, they have no mind generally to leave it: but if they riſe again the ſame or next day, be ſure hive them not in the ſame hive again, for it is plain they have ſome diſlike to it."

As ſoon as the ſwarm is ſettled, the bees which compoſe it ſhould be got into a hive with all convenient ſpeed, to prevent their taking wing again. If they ſettle on a ſmall branch of a tree, eaſy to be come at, it may be cut off, and laid upon a cloth; the hive being ready immediately to put over them. If the branch cannot be conveniently cut, the bees may be ſwept from off it into a hive. Lodge but the queen in the hive, and the reſt will ſoon follow. If the bees muſt be conſiderably diſturbed, in order to get them into a hive, the moſt adviſable way is to let them remain in the place where they have pitched, till the evening, when there is leſs danger of their taking wing. If it be obſerved that they ſtill hover about the place they firſt alighted upon, the branches there may be rubbed with rue, or elder leaves, or any other thing diſtaſteful to them, to prevent their returning to it.

The hive employed on this occaſion ſhould be cleaned with the utmoſt care, and its inſide be rubbed very hard with a coarſe cloth, to get off the looſe ſtraws, or other impurities, which might coſt them a great deal of time

and

and labour to gnaw away. It may then be rubbed with fragrant herbs or flowers, the ſmell of which is agreeable to the bees, or with honey

The hive ſhould not be immediately ſet on the ſtool where it is to remain, but ſhould be kept near the place at which the bees ſettled, till the evening, leſt ſome ſtragglers ſhould be left. It ſhould be ſhaded, either with boughs, or with a cloth, that the too great heat of the ſun may not annoy the bees.

We ſometimes ſee a ſwarm of bees, after having left their hive, and even alighted upon a tree, return to their firſt abode. This never happens but when the young queen did not come forth with them, for want of ſtrength, or perhaps courage to truſt to her wings for the firſt time; or poſſibly from a conſciouſneſs of her not being impregnated.

Bees are not apt to ſting when they ſwarm: therefore it is not neceſſary then to take much extraordinary precaution againſt them. It is however adviſable for thoſe who are not accuſtomed to them, to cover their face and hands.

A ſecond ſwarm ſcarcely is, and much leſs are the ſubſequent ones, worth keeping ſingle; becauſe, being few in number, they cannot allow ſo large a proportion of working bees to go abroad in ſearch of ſtore, as more numerous ſwarms can, after having appointed a proper number for the various works to be done within. For this reaſon it is adviſable to unite two or more of theſe laſt or latter ſwarms into one hive, ſo as to procure a ſufficient number of bees in one hive. Bees ſometimes ſwarm ſo often, that the mother-hive is too much weakened. In this caſe, the ſwarms ſhould be reſtored back; and this ſhould alſo be done when a ſwarm produces a ſwarm the firſt ſummer, as it ſometimes does. The beſt way, indeed, is to prevent ſuch ſwarming, by giving the bees more room: though this, again, will not anſwer where there is a young pregnant queen; ſhe well knowing that her life is the forfeit of her remaining at home.

The uſual method of uniting ſwarms is very eaſy. Spread a cloth at night upon the ground cloſe to the hive in which the two caſts or ſwarms are to be united; lay a ſtick acroſs this cloth; then fetch the hive with the new ſwarm, ſet it over the ſtick, give a ſmart ſtroke on the top of the hive, and all the bees will drop down upon the cloth, in a cluſter. This done, throw aſide the empty hive, take the other from off the ſtool, and ſet this laſt over the bees, who will ſoon aſcend into it, mix with thoſe already there, and become one and the ſame family. Others, inſtead of ſtriking the bees down upon the cloth, place with its bottom upmoſt the hive in which the united ſwarms aae to live, and ſtrike the bees of the other hive down into it. The former of theſe hives is then reſtored to its natural ſituation, and the bees of both hives ſoon unite. If ſome bees ſtill adhere to the other hive, they may be bruſhed off on the cloth, and they will ſoon join their brethren. Or one may take the following method, which gives leſs diſturbance to the bees. Set with its mouth upmoſt the hive into which the young ſwarm has been put, and ſet upon it the other hive. The bees in the lower hive, finding themſelves in an inverted ſituation, will ſoon aſcend into the upper.

Though all writers acknowledge, that one of the queens is conſtantly ſlain on theſe occaſions, and generally a conſiderable number of the working bees; yet none of them, Columella excepted, has propoſed the eaſy remedy of killing the queen of the latter caſt or ſwarm before the union is made; a means by which the lives of the working bees may be preſerved. This may be done, either by intoxicating them, and then picking her out, or by ſearching her out when the bees are beaten down upon the cloth; for this being done in the night, to prevent the battle which might otherwiſe enſue, there will be no great difficulty in finding her.

A large ſwarm may weigh eight pounds, and ſo gradually leſs, to one pound: conſequently a very good one may weigh five or ſix pounds. All ſuch as weigh leſs than four pounds ſhould be ſtrengthened, by uniting to each of them a leſs numerous ſwarm. The ſize of the hive ſhould be proportioned to the number of the bees; and, as a general rule, it ſhould be rather under than over-ſized, becauſe bees require to be kept warmer than a large hive will admit of.

Columella directs, that the apiary, or bee-garden, face the ſouth, in a place neither too hot, nor too much expoſed to the cold; that it be in a valley, in order that the loaded bees may with the greater eaſe deſcend to their homes; that it be near the manſion-houſe, on account of the conveniency of watching them, but ſo ſituated as not to be expoſed to noiſome ſmells, or to the din of men or cattle; that it may be ſurrounded with a wall, which however ſhould not riſe above three feet high; that, if poſſible, a running ſtream be near them, or, if that cannot be, that water be brought near them in troughs, with pebbles or ſmall ſtones in the water, for the bees to reſt on whilſt they drink; or that the water be confined within gently declining banks, in order that the bees may have ſafe acceſs to it; they not being able to produce either combs, honey, or food for their maggots, without water. That the neighbourhood of rivers or baſons of water with high banks be avoided, becauſe winds may whirl the bees into them, and they cannot eaſily get on ſhore from thence to dry themſelves; and that the garden in which the apiary ſtands be well furniſhed with ſuch plants as afford the bees plenty of good paſture. The trees in this garden ſhould be of the dwarf kind, and their heads buſhy, in order that the ſwarms which ſettle on them may be the more eaſily hived.

The proprietor ſhould be particularly attentive that the bees have alſo in their neighbourhood ſuch plants as yield them plenty of food. Columella enumerates many of theſe fitted to a warm climate: among them he mentions thime, the oak, the pine, the ſweet ſmelling cedar, and all fruit trees. Experience has taught us, that furz, broom, muſtard, clover, heath, buck-wheat, &c. are excellent for this purpoſe. Pliny recommends broom, in particular, as a plant exceedingly grateful, and very profitable to bees; and Mr. Bradley ſpeaks highly of the advantages which ariſe from the planting of it for the food of theſe uſeful inſects. *See the article* BROOM.

Plantations of muſtard, of the flowers of which bees are extremely fond, may be kept in bloom for ſeveral weeks running.

Great improvements may alſo certainly be made in the eſſential article of providing plenty of paſture for bees, whenever this ſubject ſhall be more carefully attended to than it, unfortunately, has hitherto been. A rich corn country is well known to be a barren deſart to them during

during the moſt conſiderable part of the year; and therefore the practice of other nations, in ſhifting the places of abode of their bees, well deſerves our imitation.

Columella informs us, that, as few places are ſo happily ſituated as to afford the bees proper paſture both in the beginning of the ſeaſon and alſo in the autumn, it was the advice of Celcus, that after the vernal paſtures are conſumed, the bees ſhould be tranſported to places abounding with autumnal flowers; as was practiſed by conveying the bees from Achaia to Attica, from Eubœa and the Cyclad iſlands to Scyrus, and alſo in Sicily, where they were brought to Hybla from other parts of the iſland. He likewiſe directs, that the hives be carefully examined before they are removed from one place to another, and to take out ſuch combs as appear old, looſe, or have moths in them, reſerving only thoſe that are ſound, in order that the hive may be ſtored with combs collected from the beſt flowers.

M. Maillet, in his curious deſcription of Egypt, relates, that "ſpite of the ignorance and ruſticity which have got poſſeſſion of that country, there yet remain in it ſeveral footſteps of the induſtry and ſkill of the antient Egyptians. One of their moſt admirable contrivances is, their ſending their bees annually into diſtant countries, in order to procure them ſuſtenance there, at a time when they could not find any at home; and their afterwards bringing them back, like ſhepherds who ſhould travel with their flocks, and make them feed as they go. It was obſerved by the antient inhabitants of Lower Egypt, that all plants bloſſomed, and the fruits of the earth ripened, above ſix weeks earlier in Upper Egypt, than with them. They applied this remark to their bees; and the means then made uſe of by them, to enable theſe uſeful induſtrious inſects to reap advantage from the more forward ſtate of nature there, were exactly the ſame as are now practiſed, for the like purpoſe, in that country. About the end of October, all ſuch inhabitants of the Lower Egypt as have hives of bees, embark them on the Nile, and convey them upon that river quite into Upper Egypt; obſerving to time it ſo that they arrive there juſt when the inundation is withdrawn, the lands have been ſown, and the flowers begin to bud. The hives thus ſent are marked and numbered by their reſpective owners, and placed pyramidically in boats prepared for the purpoſe. After they have remained ſome days at their fartheſt ſtation, and are ſuppoſed to have gathered all the wax and honey they could find in the fields within two or three leagues around, their conductors convey them, in the ſame boats, two or three leagues lower down, and there leave the laborious inſects ſo long time as is neceſſary for them to collect all the riches of this ſpot. Thus, the nearer they come to the place of their more permanent abode, they find the productions of the earth, and the plants which afford them food, forward in proportion. In fine, about the beginning of February, after having travelled through the whole length of Egypt, gathering all the rich produce of the delightful banks of the Nile, they arrive at the mouth of that river, towards the ocean; from whence they ſet out, and from whence they are now returned to their ſeveral homes: for care is taken to keep an exact regiſter of every diſtrict from whence the hives were ſent in the beginning of the ſeaſon, of their numbers, of the names of the perſons who ſent them, and likewiſe of the mark or number of the boat in which they were placed."

The author of the Natural Hiſtory of Bees gives the following account of what is practiſed in this way in France; an example well worth our imitation in many parts of this kingdom. "M. Proutaut, ſays he, keeps a great number of hives. His ſituation is one of thoſe in which flowers become rare or ſcarce very ſoon, and where few or none are ſeen after the corn is ripened. He then ſends his bees into Beauce, or the Gatinois, in caſe it has rained in thoſe parts. This is a journey of about twenty miles, which he makes them take. But if he concludes that the bees could not meet, in either of thoſe countries, wherewith to employ themſelves advantageouſly, he then has them carried into Sologne about the beginning of Auguſt: as knowing that they will there meet with a great many fields of buck-wheat in flower, which will continue ſo till about the end of September. His method of tranſporting them is thus. His firſt care is, to examine thoſe hives, ſome of whoſe honey-combs might be broken or ſeparated by the jolting of the vehicle: they are made faſt one to the other, and againſt the ſides of the hive, by means of ſmall ſticks, which may be diſpoſed differently as occaſion will point out. This being done, every hive is ſet upon a packing-cloth, or ſomething like it, the threads of which are very wide: the ſides of this cloth are then turned up, and laid on the outſide of each hive, in which ſtate they are tied together with a piece of ſmall pack-thread wound ſeveral times round the hive. As many hives as a cart built for that purpoſe will hold, are afterwards placed in this vehicle. The hives are ſet two and two, the whole length of the cart. Over theſe are placed others; which make, as it were, a ſecond ſtory or bed of hives. Thoſe which are ſtored with combs ſhould always be turned topſy-turvy. It is for the ſake of their combs, and to fix them the better, that they are diſpoſed in this manner; for ſuch as have but a ſmall quantity of combs in them, are placed in their natural ſituation. Care is taken in this ſtowage, not to let one hive ſtop up another: it being eſſentially neceſſary for the bees to have air; and it is for this reaſon they are wrapped up in a coarſe cloth, the threads of which were wove very wide, in order that the air may have a free paſſage, and leſſen the heat which theſe inſects raiſe in their hives; eſpecially when they move about very tumultuouſly, as often happens in theſe carts. Thoſe uſed for this purpoſe in Yévre, hold from thirty to forty-eight hives. As ſoon as all are thus ſtowed, the caravans ſet out. If the ſeaſon is ſultry, they travel only in the night; but a proper advantage is made of cool days. You will imagine that they do not ride poſt. The horſes muſt not be permitted even to trot; they are led ſlowly, and through the ſmootheſt roads. When there are not combs in the hives ſufficient to ſupport the bees during their journey, the owner takes the earlieſt opportunity of reſting them wherever they can collect wax. The hives are taken out of the cart, then ſet upon the ground, and after removing the cloth from over them, the bees go forth in ſearch of food. The firſt field they come to ſerves them as an inn. In the evening, as ſoon as they are all returned, the hives are ſhut up; and being placed again in the cart, they proceed in their journey. When the caravan is arrived at the journey's end, the hives are diſtributed in the gardens; or in fields adjacent to the houſes of

different peaſants, who, for a very ſmall reward, undertake to look after them. Thus it is that, in ſuch ſpots as do not abound with flowers at all ſeaſons, means are found to ſupply the bees with food during the whole year."

Theſe inſtances of the great advantages which attend ſhifting of bees in ſearch of paſture, afford an excellent leſſon to many places in this kingdom: they direct particularly the inhabitants of the rich vales, where the harveſt for bees ends early, to remove their ſtocks to places which abound in heath, this plant continuing in bloom during a conſiderable part of the autumn, and yielding great plenty of food to bees. Thoſe in the neighbourhood of hills and mountains will ſave the bees a great deal of labour, by taking alſo the advantage of ſhifting their places of abode.

We come now to explain the moſt inhuman method commonly practiſed of taking bees, which conſiſts in wantonly deſtroying the whole ſwarm, in order to enjoy the fruits of their labours.

Were we to kill the hen for her egg, the cow for her milk, or the ſheep for the fleece it bears, every one would inſtantly ſee how much we ſhould act contrary to our own intereſt: and yet this is practiſed every year in regard to bees. Would it not argue more wiſdom in us to be contented with taking away only a portion of their wax and honey, as is the practice of many countries? The common method here is, that when thoſe which are doomed for ſlaughter have been marked out (which is generally done in September) a hole is dug near the hive, and a ſtick, at the end of which is a rag that has been dipped in melted brimſtone, being ſtuck in that hole, the rag is ſet on fire, the hive is immediately ſet over it, and the earth is inſtantly thrown up all around, ſo that none of the ſmoke can eſcape. In a quarter of an hour, all the bees are ſeemingly dead; and they will ſoon after be irrecoverably ſo, by being buried in the earth that is returned back into the hole: I ſay, they will ſoon be abſolutely killed by this laſt means; becauſe it has been found, by experiment, that all the bees which have been affected only by the fume of the brimſtone, recover again, excepting ſuch as have been ſinged or hurt by the flame. Hence it is evident, that the fume of brimſtone might be uſed for intoxicating the bees, with ſome few precautions. The heavieſt and the lighteſt hives are alike treated in this manner; the former, becauſe they yield the moſt profit, with an immediate return; and the latter, becauſe they would not be able to ſurvive the winter. Thoſe hives which weigh from fifteen to twenty pounds, are thought to be the fitteſt for keeping.

The practice of the ancients was, however, very different from this: they were content to ſhare with theſe induſtrious inſects the produce of their labours; and ſome very laudable attempts have been made in our own country, to attain the deſirable end of getting the honey and wax without deſtroying the bees. John Geddy, Eſq; publiſhed in the year 1665, his invention of boxes for preſerving the lives of bees. Theſe were improved by Joſeph Warder, phyſician, at Croydon, who at the ſame time embelliſhed his account of the ſtructure and uſe of theſe boxes, with ſeveral other curious circumſtances concerning bees in his work intitled, The True Amazons, or the Monarchy of Bees. Two very worthy clergymen, the reverend Mr. John Thorley of Oxford, and the reverend Mr. Stephen White, M. A. rector of Holton in Suffolk, have brought the method of preſerving the lives of bees to ſtill greater perfection. We ſhall relate the opinions and practice of each, beginning with Mr. Thorley, who lived many years before Mr. White, and add to their accounts the beſt improvements that have been lately made in foreign countries.

Mr. Thorley, in his Enquiry into the Nature, Order, and Government of Bees, thinks colonies preferable to hives, for the following reaſons. Firſt, the more certain preſervation of very many thouſands of theſe noble and uſeful creatures: Secondly, their greater ſtrength (which conſiſts in numbers) and conſequently their greater ſafety from robbers: Thirdly, their greater wealth, ariſing from the united labours of the greater number. He tells us, that he has in ſome ſummers taken two boxes filled with honey from one colony: and yet ſufficient ſtore has been left for their maintenance during the winter, each box weighing forty pounds. Add to theſe advantages, the pleaſure of viewing them with the greateſt ſafety, at all ſeaſons, even in their buſieſt time of gathering, and their requiring a much leſs attendance in ſwarming time. The bees thus managed are alſo more effectually ſecured from wet and cold, from mice and other vermin.

His boxes are made of deal, which, being ſpungy, ſucks up the breath of the bees ſooner than a more ſolid wood would do. Yellow dram-deal, thoroughly ſeaſoned, is the beſt.

An octagon, being nearer to a ſphere, is better than a ſquare form: for as the bees, in winter, lie in a round body near the center of the hive, a due heat is then conveyed to all the out-parts, and the honey is kept from candying.

The dimenſions which Mr. Thorley, after many years experience, recommends for the boxes, are ten inches deep, and twelve or fourteen inches broad, in the inſide. He has tried boxes containing a buſhel or more, but found them not to anſwer the deſign like thoſe of a leſſer ſize.

The top of the box ſhould be made of an entire board, a full inch thick after it has been planed, and it ſhould project on all ſides at leaſt an inch beyond the dimenſions of the box. In the middle of this top there muſt be a hole five inches ſquare, for a communication between the boxes; and this hole ſhould be covered with a ſliding ſhutter, of deal or elm, running eaſily in a groove over the back window. The eight pannels, nine inches deep, and three quarters of an inch thick when planed, are to be let into the top ſo far as to keep them in their proper places; to be ſecured at the corners with plates of braſs, and to be cramped with wires at the bottom, to keep them firm: for the heat in ſummer will try their ſtrength. There ſhould be a glaſs window behind, fixed in a frame, with a thin deal cover, two ſmall braſs hinges, and a button to faſten it. This window will be ſufficient for inſpecting the progreſs of the bees. Two braſs handles, one on each ſide, are neceſſary, to lift up the box: theſe ſhould be fixed in with two thin plates of iron, near three inches long, ſo as to turn up and down, and put three inches below the top-board, which is nailed cloſe down with ſprings to the other parts of the box.

Thoſe who chuſe a frame within, to which the bees may faſten their combs, need only uſe a couple of deal

ſticks

ſticks of an inch ſquare, placed acroſs the box, and ſupported by two pins of braſs; one an inch and a half below the top, and the other two inches below it; by which means the combs will quickly find a reſt. One thing more, which perfects the work, is a paſſage four or five inches long, and leſs than half an inch deep, for the bees to go in and out at the bottom of the box.

Mr. Thorley, ſon to the above-mentioned clergyman has improved his father's method of managing bees; and having been convinced from near ſixty years experience, that his bee-hives would be productive of much greater profit to the owners of bees, and alſo render that cruel and ungenerous practice of deſtroying theſe animals not only unneceſſary, but pernicious, preſented a bee-hive of this conſtruction to the Society of Arts, &c, in the Strand, who readily purchaſed another of his hives filled with honey, &c. that they might be inſpected by the curious, and brought into univerſal uſe; and from this bee-hive the view on Plate III. Fig. 8, was drawn. The Society, perſuaded that the invention would prove of the greateſt advantage to this country, publiſhed a premium of two hundred pounds, in order to introduce Mr. Thorley's, or ſome other method of a ſimilar kind, whereby much larger quantities of honey and wax might be procured, and, at the ſame time, the lives of theſe laborious and uſeful inſects preſerved.

The bottom part, marked *a*, is an octangular bee-box, made of deal boards, about an inch in thickneſs, the cover of which is about 17 inches in diameter, but the internal part only 15½ and its height 10 inches. In the middle of the cover of this octangular box is a hole, which may be opened or ſhut at pleaſure, by means of a ſlider *d*. In one of the pannels is a pane of glaſs, covered with a wooden door, *e*. The entrance, *f*, at the bottom of the box is about three inches and a half broad, and half an inch high. Two ſlips of deal, about half an inch ſquare, croſs each other in the center of the box, and are faſtened to the pannels by means of ſmall ſcrews. To theſe ſlips the bees faſten their combs.

In this octangular box the bees are hived, after ſwarming in the uſual manner, and there ſuffered to continue till they have built their combs, and filled them with honey, which may be known from opening the door, and viewing their works through the glaſs pane, or by the weight of the hive. When the bee-maſter finds his laborious inſects have filled their habitation, he is to place a common bee-hive of ſtraw, repreſented at *b*, made either flat at the top, or in the common form, on the octangular box, and draw out the ſlider, by which a communication will be opened between the box and the ſtraw hive; the conſequence of which will be, that thoſe laborious inſects will fill this hive alſo with the product of their labours. When the bee-maſter finds the ſtraw hive is well filled, he may puſh in the ſlider, and take it away, placing another immediately in its room, and then drawing out the ſlider. Theſe indefatigable creatures will then fill the new hive in the ſame manner. By proceeding in this method, Mr. Thorley aſſured the Society that he had taken three ſucceſſive hives, filled with honey and wax, from one ſingle hive, during the ſame ſummer; and that after he had laid his inſects under ſo large a contribution, the food ſtill remaining in the octangular box was abundantly ſufficient for their ſupport during the winter. He added, that if this method was purſued in every part of the kingdom, inſtead of that cruel method of putting the creatures to death, he was perſuaded, from long experience, that wax would be collected in ſuch plenty that candles might be made with it, and ſold as cheap as thoſe of tallow are at preſent.

Mr. Thorley has alſo added another part to his bee-hive, which cannot fail of affording the higheſt entertainment to a curious and inquiſitive mind. It conſiſts of a glaſs receiver, repreſented at D, eighteen inches in height, eight inches in diameter at the bottom, and in the greateſt part thirteen. This receiver has a hole at the top, about an inch in diameter, through which a ſquare piece of deal E is extended nearly to the bottom of the veſſel, having two croſs bars to which the bees faſten their combs. When the bees have filled their ſtraw hive, (which muſt have a hole in the center, covered with a piece of tin) Mr. Thorley places the glaſs *c* upon the top of the ſtraw hive, and draws out the piece of tin: the bees, now finding their habitation enlarged, purſue their labours with ſuch alacrity, that they fill this glaſs hive likewiſe with their ſtores. And as this receptacle is wholly tranſparent, the curious obſerver may entertain himſelf with viewing the whole progreſs of their works. One of the hives, now depoſited at the Society's rooms in the Strand, is filled with the produce of the labours of thoſe inſects; and the glaſs-hive is ſuppoſed to contain about thirty-eight pounds of honey.

It will, however, be neceſſary to cover the glaſs with an empty hive of ſtraw, or at leaſt with a cloth, which may be eaſily removed when you inſpect your bees, leſt too much light prevent your inſects from working.

When the glaſs is completely filled, ſlide a tin-plate between it and the hive or box, ſo as to cover the paſſage, and in half an hour the glaſs may be taken off with ſafety. What few bees remain in it, will readily go to their companions. He then very obligingly offers his ſervice and farther information to any gentleman or lady whoſe curioſity may incline them to inſpect his apiary. He has added a glaſs window to his ſtraw-hives, in order to ſee what progreſs the bees make; which is of ſome importance, eſpecially if one hive is to be taken away whilſt the ſeaſon ſtill continues favourable for their collecting of honey: for when the combs are filled with honey, the cells are ſealed up, and the bees forſake them, and reſide moſtly in the hive in which their works are chiefly carried on. Obſerving alſo, that the bees were apt to extend their combs through the paſſage of communication into the upper hive, whether glaſs or other, which rendered it neceſſary to divide the combs when the upper hive was taken away, he now puts in that paſſage a wire ſcreen, or netting, the meſhes of which are large enough for a loaded bee to go eaſily thro' them, this prevents the joining of the combs from one box to the other, and conſequently obviates the neceſſity of cutting them, and of ſpilling ſome honey, which, running down amongſt a croud of bees, uſed before to incommode them much; it being difficult for them to clear their wings of it.

The reverend Mr. Stephen White, rector of Holton in Suffolk, informs us, that his fondneſs for theſe little animals ſoon put him upon endeavouring, if poſſible, to

ſave them from *fire* and *brimſtone*; that he thought he had reaſon to be content to ſhare their labours for the preſent, and great reaſon to rejoice if he could at any time preſerve their lives, to work for him another year; and that the main drift of his obſervations and experiments has therefore been, to diſcover an eaſy and cheap method, ſuited to the abilities of the common people, of taking away ſo much honey as can be ſpared, without deſtroying or ſtarving the bees; and by the ſame means to encourage ſeaſonable ſwarms.

In his directions how to make the bee-boxes of his inventing, he tells us, ſpeaking of the manner of conſtructing a ſingle one, that it may be made of deal or any other well ſeaſoned boards which are not apt to warp or ſplit. The boards ſhould be near an inch thick: the figure of the box ſquare, and its heighth and breadth nine inches and five eighths, every way meaſuring within. With theſe dimenſions it will contain near a peck and an half. The front part muſt have a door cut in the middle of the bottom edge, three inches wide, and near half an inch in height, which will give free liberty to the bees to paſs through, yet not be large enough for their enemy the mouſe to enter. In the back part you muſt cut a hole with a rabbit in it, in which you are to fix a pane of the cleareſt and beſt crown-glaſs, about five inches in length, and three in breadth, and faſten it with putty: let the top of the glaſs be placed as high as the roof within-ſide, that you may ſee the upper part of the combs, where the bees with their riches are moſtly placed. You will, by this means, be better able to judge of their ſtate and ſtrength, than if your glaſs was fixed in the middle. The glaſs muſt be covered with a thin piece of board, by way of ſhutter, which may be made to hang by a ſtring, or turn upon a nail, or ſlide ſideways between two mouldings. Such as are deſirous of ſeeing more of the bees works, may make the glaſs as large as the box will admit, without weakening it too much: or they may add a pane of glaſs on the top, which muſt likewiſe be covered with a ſhutter, faſtened down with pegs to prevent accidents.

The ſide of the box which is to be joined to another box of the ſame form and dimenſions, as it will not be expoſed to the external air, may be made of a piece of ſlit deal not half an inch thick. This he calls the ſide of communication, becauſe it is not to be wholly incloſed: a ſpace is to be left at the bottom the whole breadth of the box, and a little more than an inch in height, and a hole or paſſage is to be made at top, three inches long, and more than half an inch wide. Through theſe the bees are to have a communication from one box to the other. The lower communication being on the floor, our labourers, with their burthens, may readily and eaſily aſcend into either of the boxes. The upper communication is only intended as a paſſage between the boxes, reſembling the little holes, or narrow paſſes, which may be obſerved in the combs formed by our ſagacious architects, to ſave time and ſhorten the way when they have occaſion to paſs from one comb to another; juſt as, in populous cities, there are narrow lanes and alleys, paſſing tranſverſly from one large ſtreet to another.

In the next place you are to provide a looſe board, half an inch thick, and large enough to cover the ſide where you have made the communication. You are likewiſe to have in readineſs ſeveral little iron ſtaples, an inch and half long, with the two points or ends bended down more than half an inch. The uſe of theſe will be ſeen preſently.

You have now only to fix two ſticks croſſing the box from ſide to ſide, and croſſing each other, to be a ſtay to the combs; one about three inches from the bottom, the other the ſame diſtance from the top; and when you have painted the whole, to make it more durable, your box is finiſhed.

The judicious bee-maſter will here obſerve, that the form of the box now deſcribed is as plain as is poſſible for it to be. It is little more than five ſquare pieces of board nailed together; ſo that a poor cottager, who has but ingenuity enough to ſaw a board into the given dimenſions, and to drive a nail, may make his own boxes well enough, without the help or expence of a carpenter.

No directions are neceſſary for making the other box, which muſt be of the ſame form and dimenſions. The two boxes differ from each other only in this, that the ſide of communication of the one muſt be on your right-hand; of the other on the left. Plate III. Fig. 9. repreſents two of theſe boxes, with their openings of communication, ready to join to each other.

Mr. White's manner of hiving a ſwarm into one or both of theſe boxes, is thus.

You are to take the looſe board, and faſten it to one of the boxes, ſo as to ſtop the communications. This may be done by three of the ſtaples before mentioned; one on the top of the box near the front, the two others on the back, near the top and near the bottom. Let one end of the ſtaple be thruſt into a gimblet-hole made in the box, ſo that the other end may go as tight as can be over the looſe board, to keep it from ſlipping when it is handled. The next morning, after the bees have been hived in this box, the other box ſhould be added, and the looſe board ſhould be taken away. This will prevent a great deal of labour to the bees, and ſome to the proprietor.

Be careful to faſten the ſhutter ſo cloſe to the glaſs, that no light may enter through it; for the bees ſeem to look upon ſuch light, as a hole or breach in their houſe, and on that account may not ſo well like their new habitation. But the principal thing to be obſerved at this time, is to cover the box, as ſoon as the bees are hived, with a linnen cloth thrown looſely over it, or with green boughs, to protect it from the piercing heat of the ſun. Boxes will admit the heat much ſooner than ſtraw hives; and if the bees find their houſe too hot for them, they will be wiſe enough to leave it. If the ſwarm be larger than uſual, inſtead of faſtening the looſe board to one box, you may join two boxes together with three ſtaples, leaving the communication open from one to the other, and then hive your bees into both. In all other reſpects, they are to be hived in boxes after the ſame manner as in common hives; which being well known, it were needleſs here to give particular directions concerning it.

The door of the ſecond box ſhould be carefully ſtopped up, and be kept conſtantly cloſed, in order that the bees may not have any entrance but through the firſt box.

When the boxes are ſet in the places where they are to remain, they muſt be ſcreened from the ſummer's ſun, becauſe the wood will otherwiſe be heated to a greater degree than either the bees or their works can bear; and they ſhould likewiſe be ſcreened from the winter's ſun, becauſe the warmth of this will draw the bees from that lethargic

ſtate which is natural to them, as well as to many other inſects, in the winter ſeaſon. For this purpoſe, and alſo to ſhelter the boxes from rain, our ingenious clergyman has contrived the following frame.

Plate III. Fig. 10. repreſents the front of a frame for twelve colonies. *a*, *a*, are two cells of oak, lying flat on the ground, more than four feet long. In theſe cells you are to fix four oaken poſts, about the thickneſs of ſuch as are uſed for drying linen.

The two poſts *b*, *b*, in the front, are about ſix feet two inches above the cells: the other two ſtanding backward, five feet eight inches.

You are next to nail ſome boards of ſlit deal horizontally from one of the fore-poſts to the other, to ſcreen the bees from the ſun. Let theſe boards be ſeven feet ſeven inches in length, and nailed to the inſide of the poſts, and be well ſeaſoned, that they may not ſhrink or gape in the joints.

c, *c*, are two ſplines of deal, to keep the boards even, and ſtrengthen them.

Plate III. Fig. 11. repreſents the back of the frame. *d*, *d*, *d*, *d*, are four ſtrong boards of the ſame length with the frame, on which you are to place the boxes. Let the upper ſide of them be very ſmooth and even, that the boxes may ſtand true upon them: or it may be ſtill more adviſable, to place under every pair of boxes a ſmooth thin board, as long as the boxes, and about a quarter of an inch wider. The bees will ſoon faſten the boxes to this board, in ſuch manner, that you may move or weigh the boxes and board together, without breaking the wax or reſin, which for many reaſons ought to be avoided. Theſe floors muſt be ſupported by pieces of wood, or bearers *e*, *e*, &c. which are nailed from poſt to poſt at each end. They are likewiſe to be well nailed to the frame, to keep them from ſinking with the weight of the boxes.

f repreſents the roof, which projects backward about ſeven or eight inches beyond the boxes, to ſhelter them from rain.

You have now only to cut niches or holes in the frame, over againſt each mouth or entrance into the boxes, at *h*, *h*, *h*, in Fig. 10. Let theſe niches be near four inches long; and under each you muſt nail a ſmall piece of wood for the bees to alight upon.

The morning or evening ſun will ſhine upon one or both ends of the frame, let its aſpect be what it will: but you may prevent its over-heating the boxes, by a looſe board ſet up between the poſts, and kept in by two or three pegs.

The ſame gentleman, with great humanity, obſerves, that no true lover of bees ever lighted the fatal match without concern; and that it is evidently more to our advantage, to ſpare the lives of our bees, and be content with part of their ſtores, than to kill and take poſſeſſion of the whole.

About the latter end of Auguſt, ſays he, by a little inſpection through your glaſſes, you may eaſily diſcover which of your colonies you may lay under contribution. Such as have filled a box and a half with their works, will pretty readily yield you the half box. But you are not to depend upon the quantity of combs, without examining how they are ſtored with honey. The bees ſhould, according to him, have eight or nine pounds left them, by way of wages for their ſummer's work.

The moſt proper time for this buſineſs is the middle of the day: and as you ſtand behind the frame, you will need no armour, except a pair of gloves. The operation itſelf is very ſimple, and eaſily performed, thus: open the mouth of the box you intend to take; then with a thin knife, cut through the reſin with which the bees have joined the boxes to each other, till you find that you have ſeparated them; and after this thruſt a ſheet of tin gently in between the boxes. The communication being thereby ſtopped, the bees in the fulleſt box, where it moſt likely the queen is, will be a little diſturbed at the operation; but thoſe in the other box, where we ſuppoſe the queen is not, will run to and fro in the utmoſt hurry and confuſion, and ſend forth a mournful cry, eaſily diſtinguiſhed from their other notes. They will iſſue out at the newly opened door; not in a body, as when they ſwarm, nor with ſuch calm and chearful activity as when they go forth to their labours; but by one or two at a time, with a wild flutter, and viſible rage and diſorder. This, however, is ſoon over; for as ſoon as they get abroad, and ſpy their fellows, they fly to them inſtantly, and join them at the mouth of the other box. By this means, in an hour or two, for they go out ſlowly, you will have a box of pure honey, without a living bee in it to moleſt you; and likewiſe without dead bees, which, when you harm them, are often mixed with your honey, and both waſte and damage it.

The indefatigable Mr. Wildman has obliged the world with the following method of taking the wax and honey, without deſtroying the bees:

Remove, ſays he, the hive from which you would take the wax and honey into a room, into which admit but little light, that it may at firſt appear to the bees as if it were late in the evening. Gently invert the hive, placing it between the frames of a chair, or other ſteady ſupport, and cover it with an empty hive, keeping the ſide next the window of the empty hive raiſed a little to give the bees ſufficient light to get into it. While you hold the empty hive ſteadily ſupported on the edge of the full hive, between your ſide and your left arm, keep ſtriking with your other hand all round the full hive from top to bottom, in the manner of beating a drum, ſo that the bees may be frightened by the continual noiſe from all quarters; and they will in conſequence mount out of the full hive into the empty one. Repeat the ſtrokes rather quick than ſtrong round the hive, till all the bees are got out of it, which will generally be in about five minutes. It is to be obſerved, that the fuller the hive is of bees, the ſooner they will have left it. As ſoon as a number of them have got into the empty hive, it ſhould be raiſed a little from the full one, that the bees may not continue to run from the one to the other. And as ſoon as all the bees are out of the full hive, the other, in which the bees are, muſt be placed on the ſtand from which the former hive was taken, in order to receive the abſent bees as they return from the fields.

If this be done early in the ſeaſon, the operator ſhould examine the royal cells; for if any of them contain young bees, they muſt, as well as all the combs that have young bees in them, be ſaved in the hive. Take out the other combs with a long broad and pliable knife; cutting them from the ſides and crown as clean as poſſible, to ſave the future labours of the bees, who muſt lick up the honey

ſpilt,

ſpilt, and remove every grain of wax: the ſides of the hive ſhould then be ſcraped with a table ſpoon, to clear away what was leſt by the knife.

Having thus finiſhed taking the wax and honey, let a table covered with clean cloth be placed near the ſtand, and giving the hive in which the bees are a ſudden ſhake, ſtriking it at the ſame time pretty forcibly, the bees will be ſhaken on the cloth. Put their own hive over them immediately, raiſed a little on one ſide, that the bees may the more eaſily enter, and where all are entered, place it on the ſtand as before. If the hive in which the bees are, be turned uppermoſt, and their own hive placed over it, the bees will immediately aſcend into it, eſpecially if the lower ſides be ſtruck to alarm them: for the effects of fear impreſſed on the bees, by the continual noiſe, renders them for a conſiderable time ſo mild and tractable, that they will bear any handling, which does not hurt them, without any ſhew of reſentment.

Madame Vicat, a very ingenious lady in Swiſſerland, publiſhed in the Memoirs of the Berne Society for the year 1764, very judicious obſervations on bees and hives, particularly thoſe which are added one to another in the manner above deſcribed. Her remarks will deſerve our attention; and therefore we ſhall give here her own account of them.

On the ninth of June 1761, this lady bought an hive of bees, in a ſtraw hive. The combs were emptied of their honey, and thereby rendered the more liable to be attacked by the moth. She placed it in a little garden in the heart of the city of Lauſanne. She ſoon diſcovered there were moths in it, and that the bees had lice on them; which determined her to place a glaſs hive over the ſtraw one, and to ſhut up the opening into the lower hive. She frequently looked into the glaſs hive, to ſee what paſſed in it. The bees never ſtopped in it, and it ſerved only as a thoroughfare to the ſtraw hive. The bees, though very laborious and numerous, could not defend themſelves againſt the moths, which multiplied daily: on the eighteenth of July her bees were reduced to little more than three hundred. Finding their number decreaſe every day, ſhe ſuſpected that ſome accident had happened to the queen, which upon examination ſhe found to be true; as ſhe alſo did, that theſe moths may ſoon deſtroy the moſt numerous hive. They had mouldered away the wax, and had united the three middle combs, by their galleries, to ſuch a degree, that they appeared but as one maſs. Upon turning up the hive, to ſee what condition it was in, ſhe found the ſides covered with white and hard cocoons, which would ſoon produce moths. They were in ſuch quantity as to fill the crown of her hat.

It appears to her that the moths are moſt ready to attack hives which have ſwarmed oftener than once; becauſe in them the combs, in which the young bees were reared, being empty, ſerve for both ſhelter and food to their maggots, which feed only on wax. For the ſame reaſon, late ſwarms, and hives in which there is not much honey, are equally expoſed to theſe inſects. Such hives ſhould therefore be cleaned at leaſt once a week. If moths are found on the ſtool of the hive, it ſhould be cleaned every morning. In order to do this the more eaſily, without diſturbing the bees, or running the hazard of being ſtung by them, ſhe cauſed a large ſquare hole to be made in the ſtools on which her bees ſtand, with a ſlider underneath, fitted to it. By this means ſhe preſerved another hive, which ſhe had placed in the ſame garden on the ſame day, June nine, 1761: and though it was a ſwarm put into a new ſtraw hive, ſhe obſerved moths in it by the end of July. She calls this hive Numb. 1.

When ſhe ſecured this hive for the winter, ſhe put it into a dry room; but the air there being too mild, the bees conſumed almoſt their whole ſtore. She drew the ſlider often; for the diſaſter which happened to her other hive rendered her now more attentive, and ſhe generally found a quantity of moths on it. The combs became mouldy, which ſhe endeavoured to wipe off with ſoft brown paper, and rubbed it off the ſides of the hive with a napkin. So many bees died during the winter, that the hive became very weak in compariſon to what it was in the autumn. About the middle of March, ſhe placed it in a little garden ſurrounded with houſes.

She placed near the former a ſwarm of June 1761, which had been kept in a hive of Mr. Paltau's conſtruction, and had ſtood the preceding ſummer in the country, and the winter in a green-houſe in town, where the air was conſtantly kept temperate. Few of theſe bees died. She calls this hive Numb. 2.

That ſhe might judge of the ſtrength of theſe hives, ſhe counted the bees which entered into each of them in a quarter of an hour, taking the ſame hour of a fine day. She repeated this during ſeveral weeks, and found that about ſix hundred and ſixty entered in Numb. 2, and two hundred, or ſometimes two hundred and twenty, in the ſame time, into Numb. 1.

In May, the numbers of bees were ſo much increaſed, that it was no longer poſſible to count them. Numb. 1. was now as well ſtocked with bees as Numb. 2. She had been particularly careful of the former, and had fed them with honey in rainy weather. She had cleaned the ſlider every morning, and often found on it even four moths at a time. She thinks that the bees can eaſily pull them out of their holes before their galleries have been ſtrengthened with croſs threads, and cemented with the crumbs of wax, or their excrements. The bees do not always carry them out of the hive, but ſometimes leave them on the ſtool, where the little maggots ſoon weave a caſe to conceal themſelves in; as ſhe has known them do in a few hours. She found the greateſt number of them at about four or five o'clock in the morning.

She reſolved to place over Numb. 1. a glaſs hive, to give the bees an opportunity of working in it. With this view, ſhe cut ſome rounds of the top of the ſtraw hive, ſo as to make an opening of four inches, upon which ſhe put a piece of board with a correſponding opening of four inches; and on the twenty-fifth of March 1762, a glaſs hive was placed over it. She ſhut up the mouth of the ſtraw hive, in order to oblige the bees to enter by an opening under the glaſs hive, which ſhe covered, leſt the cold might incommode or even kill her bees, which were few in number. Though they increaſed ſo much by May as to be equal with Numb. 2. yet the bees never ſtopped in the glaſs hive. She judged from this, that they would rather deſcend, if ſhe gave them a convenient habitation below. She therefore placed under the ſtraw hive a box, which had an opening in it of eight inches, for the bees to paſs through. They ſoon

extended

extended their works downward, ſo that in a fortnight they almoſt filled the box with combs. On the eighth of July ſhe took away the glaſs hive; and though it had hitherto ſerved them only as a paſſage, they were much diſconcerted when it was removed: for after ſhe had filled up the opening in the top of the ſtraw hive with flax and rue, the loaded bees continued for ſeveral days to fly round it, though the rue was diſagreeable to them, before they would enter by the opening in the box, which was the only one they now had.

It is very remarkable, that the bees made no combs in the glaſs hive, though they were ſo fond of entering by it; and yet they deſcended into the box as ſoon as it was placed under them. We might have imagined it to be eaſieſt for them to enter below, at the bottom of the box; but inſtead of ſo doing, they entered by the glaſs hive, paſſed through the ſtraw hive full of combs, and carried their load down into the box. This gave her the firſt hint, that it was moſt adviſable to put the additional hive into which we would have the bees to work, under the full one, and ſhe has ſince found it ſucceed accordingly.

On the twentieth of July, ſhe found that the bees of Numb. 1. had caſt out ſo great a quantity of their young brood, that ſhe gathered ſome handfuls of it about the hive. The bees continuing to do the ſame next day, ſhe determined to take away the ſtraw hive the day after. For this purpoſe, ſhe choſe eight o'clock in the morning, which ſhe had obſerved to be the time when the greateſt number of bees were gone into the fields. She began by looſening the ſtraw hive from the board on which it reſted, and to which the bees had faſtened it with propolis. She then took the wadding out of the hole in the top of the ſtraw hive; near to which ſome linen rags were kept ſmoaking, and this ſmoke was blown into the hive by a pair of bellows. As ſoon as ſhe judged that moſt of the bees had been forced down into the box, ſhe cauſed a ſtrong iron wire to be drawn through between the hive and the board it reſted on, thereby to cut tranſverſely all the combs which were extended from the hive into the box through the hole of communication. The hive was then taken up with all the combs but one, which ſeparated from the middle of the hive. She carried this comb, with two fingers of each hand, to a table at ſome diſtance; on which the hive had been placed bottom up. The comb which ſhe carried was almoſt covered with bees; and as it fell from the middle of the hive, where the queen generally reſides, ſhe ſearched for her, and found her on the firſt round of the hive, ſcarce able to crawl, being daubed with honey which had flowed from the combs cut through. She waſhed her in a glaſs of water; but finding that this did not entirely carry off the honey which ſtill adhered to her wings, ſhe waſhed her a ſecond time, and put her among ſeveral bees which had alſo been waſhed, but had recovered ſtrength enough to aſſiſt their queen. They immediately ſet themſelves to dry and aſſiſt her. She kept her thus for half an hour, in the preſence of ſeveral curious perſons, who had often ſought in vain for her. As ſoon as ſhe thought her able to make uſe of her legs and wings, ſhe carried her to the ſtool on which the box remained, now to become the only habitation of the bees. Here ſhe was again bruſhed and licked during an hour, by bees which were in great numbers on the forepart of the box, and at laſt ſhe entered.

A farmer with whom this lady kept ſome bees in the country had an old ſtraw hive, which he intended to deſtroy in order to come at their honey and wax. She propoſed to him to follow the ſame ſteps as ſhe had taken with her's, which he agreed to, knowing that he could not loſe any thing by it. Having been taught by experience, ſhe adviſed him to put a box under the hive, rather than a hive over it. As ſhe had obſerved that her own bees had ſo obſtinately adhered to their former paſſage, ſhe adviſed him to place the box at a ſmall diſtance from the place where the hive had ſtood, that the whole might be the newer to them. They ſet to work heartily on the third of July; and by the ſixteenth of Auguſt they had lain in ſo much proviſion, that ſhe determined to take off the hive in the ſame manner as ſhe had done her own. The honey did not run ſo much, becauſe the weather was not ſo hot.

Whatever pains are taken to drive the bees out of the hive by means of ſmoke, many ſtill remain in it. In order to preſerve theſe bees, ſhe found that the beſt way was to ſweep them with the wing of a fowl into a tub of water, as faſt as the combs were taken out. This practice was attended with ſeveral advantages. It prevented the people being ſtung, it cleared the bees of any honey that might have dropped on them, and it made many of their lice fall off them.

In order to take them out of the water, ſhe cauſed a thin linen cloth to be ſpread over the mouth of an empty tub, in ſuch manner that it hung every where over the brim, and was held by one perſon, whilſt another poured the water, in which the bees were, gradually through it. The bees remained on the cloth. It is eſſential that the quantity of water be large in proportion to the number of bees, and that they be quite ſenſeleſs before they are taken out. If the firſt water taſtes of honey, they ſhould be bathed in a ſecond quantity. M. de Reaumur loſt many bees by not attending to this precaution. When the bees have been ſufficiently bathed, madam Vicat ſpreads them on whited-brown paper, which, with the warm air, ſoon dries them.

It was ſome time before this lady could find the queen of the farmer's hive. The country people who ſaw the operation, were ſtruck with great compaſſion on ſeeing ſo many bees laid out, as it were, upon the table; for they thought them quite dead, and could not believe her when ſhe aſſured them that they would all return to life. By the time ſhe had found the queen, many of the bees had ſo far recovered, as to take care of her. Madam Vicat obſerved on her crocelet a louſe, which ſhe ſtruck off with a pin. She ſaw a ſecond on the hind part of her head; but it ſtuck ſo faſt that ſhe could not remove it; nor was ſhe much ſolicitous about it, becauſe the queen ſeemed to be in good plight. All the bees were placed on the ſtool before the box; and ſhe was informed next day, that they had all ſoon returned to their companions. Having obſerved in the combs ſome cells which had young in them, ſhe put an additional height under the box, in which ſhe placed the combs with the young in them: and remarking on the twentieth of Auguſt, that there were ſeveral moths under the laſt addition, in which the combs with young were placed, ſhe judged it not to be right to preſerve ſuch combs for the future. Experience has ſince confirmed her in this opinion.

It is generally alledged, that the moths get ſo much the upper hand in the hives by the fourth year, that it is neceſſary to deſtroy the bees on the third year, in order

der to get the then remaining honey and wax; for that all would otherwiſe fall a prey to the moths. Madam Vicat has now ſhewn, that hives may be preſerved from moths without condemning to the fire thoſe precious labourers, the bees; a practice as barbarous as it is ſenſeleſs; a practice which was ſtrictly forbidden by a Grand Duke of Tuſcany, under the penalty of ſevere puniſhment, as we are informed by M. de Réaumur. If care is not taken, even three years will be too long a time to allow; for the moths will frequently deſtroy a hive the very firſt year.

The lice which ſtick to bees are not generally thought to be prejudicial to them; and this may be true when there are but few of thoſe vermin; but when every bee in a hive has two, or perhaps three lice upon it, as is often the caſe, we may believe that the bees are greatly incommoded by them: indeed we may be aſſured of it, by their uſing every means in their power, though ineffectual, to get rid of them. M. de Réaumur declares, that he cannot think well of a hive in which the greateſt number of bees have lice on them.

Madam Vicat had a hive near a chair in her garden, in which ſhe uſed to ſit at work for hours. She one day ſaw many bees endeavouring to rid themſelves of theſe troubleſome enemies, and endeavoured, but to little purpoſe, to aſſiſt them, by killing the lice with her ſciſſars. Recollecting that tobacco is a poiſon to many inſects, ſhe immediately ſtrewed a litte Morocco tobacco over ſome bees which had lice on them. The lice fell off inſtantly, as dead. In order to be aſſured that tobacco did not hurt the bees, ſhe confined ſome which were louſy, under a glaſs placed on paper ſtrewed with tobacco. After the bees had paſſed ſeveral times over the tobacco, the lice fell off them dead. She left the bees in the glaſs three hours, and at the end of that time they appeared vigorous and well.

Mr. Thorley tells us, that the beſt time to plant colonies of bees, is either in ſpring with new ſtocks full of bees, or in ſummer with ſwarms. If ſwarms are uſed, procure, if poſſible, two of the ſame day; hive them either in two boxes, or in a hive and a box; at night place them in the bee-houſe, one over the other, and, with a knife and a little lime and hair, ſtop cloſe the mouth of the hive, or upper-box, ſo that not a bee may be able to go in or out, but at the front door. This done, you will, in a week or ten days, with pleaſure ſee the combs appear in the boxes; but if it be an hive, nothing can be ſeen till the bees have wrought down into the box. Never plant a colony with a ſingle ſwarm, as Mr. Thorley ſays he has ſometimes done, but with little ſucceſs.

When the ſecond box, or the box under the hive, appears full of bees and combs, it is time to raiſe your colony. This ſhould be done in the duſk of the evening, and in the following manner.

Place your empty box, with the ſliding ſhutter drawn back, behind the houſe, near the colony that is to be raiſed, and at nearly the height of the floor; then lifting up the colony with what expedition you can, let the empty box be put in the place where it is to ſtand, and the colony upon it, and ſhut up the mouth of the then upper box, with lime and hair as before directed.

When, by the help of the windows in the back of the boxes, you find the middle box full of combs, and a quantity of honey ſealed up in it, the loweſt box half full of combs, and few bees in the uppermoſt box, proceed thus.

About five o'clock in the afternoon, drive cloſe, with a mallet, the ſliding ſhutter under the hive or box that is to be taken from the colony. If the combs are new, the ſhutter may be forced home without a mallet; but be ſure it be cloſe, that no bees may aſcend into the hive or box to be removed. After this, ſhut cloſe the doors of your houſe, and leave the bees thus cut off from the reſt of their companions for the ſpace of half an hour or more. In this time, having loſt their queen, they will fill themſelves with honey, and be impatient to be ſet at liberty.

If, in this interval, you examine the box or boxes beneath, and obſerve all to be quiet in them, you may be confident that the queen is there, and in ſafety. Hereupon raiſe the back part of the hive or box ſo far, by a piece of wood ſlipped under it, as to give the priſoners room to come out, and they will return to their fellows: then lifting the box from off the colony, and turning it bottom upmoſt, cover it with a cloth all night; and the next morning, when this cloth is removed, the bees that may have remained in it will return to the colony. Thus you have a hive or box of honey, and all your bees ſafe.

Mr. Thorley adds, that the method he has purſued with great ſucceſs for many years, and which he recommends to the public, as the moſt effectual for preſerving bees in common hives, is incorporation, or uniting two ſtocks into one, by the help of a peculiar fume or opiate, which will put them intirely in your power for a time, to divide and diſpoſe of at pleaſure. But as that dominion over them will be of ſhort duration, you muſt be expeditious in this buſineſs.

The queen is immediately to be ſearched for, and killed. Hives which have ſwarmed twice, and are conſequently reduced in their numbers, are the fitteſt to be joined together, as this will greatly ſtrengthen and improve them. If a hive which you would take is both rich in honey, and full of bees, it is but dividing the bees into two parts, and putting them into two boxes, inſtead of one. Examine whether the ſtock to which you intend to join the bees of another, have honey enough in it to maintain the bees of both: it ſhould weigh full twenty pounds.

The narcotic, or ſtupefying fume, is made with the *fungus maximus* or *pulverulentus*, the large muſhroom, commonly known by the name bunt, puckfiſt, or frog-cheeſe. It is as big as a man's head, or bigger: when ripe, it is of a brown colour, turns to powder, and is exceeding light. Put one of theſe pucks into a large paper, preſs it therein to two-thirds, or near half the bulk of its former ſize, and tie it up very cloſe; then put it into an oven ſome time after the houſhold bread has been drawn, and let it remain there all night: when it is dry enough to hold fire, it is fit for uſe. The manner of uſing it is thus:

Cut off a piece of the puck, as large as a hen's egg, and fix it in the end of a ſmall ſtick ſlit for that purpoſe, and ſharpened at the other end, which place ſo that the puck may hang near the middle of an empty hive. This hive muſt be ſet with the mouth upward, in a pail or bucket, which ſhall hold it ſteady, near the ſtock you intend to take. This being done, ſet fire to the puck, and immediately place the ſtock of bees over it, tying a cloth round the hives, that no ſmoke may come forth. In a

minute's

minute's time, or little more, you will hear the bees fall like drops of hail into the empty hive. You may then beat the top of the full hive gently with your hand, to get as many of them as you can: after this, looſing the cloth, liſt the hive off to a table, knock it ſeveral times againſt the table, ſeveral more bees will tumble out, and perhaps the queen among them. She often is one of the laſt that falls. If ſhe is not there, ſearch for her among the main body in the empty hive, ſpreading them for this purpoſe on a table.

You muſt proceed in the ſame manner with the other hive, with the bees of which theſe are to be united. One of the queens being ſecured, you muſt put the bees of both hives together, mingle them thoroughly, and drop them among the combs of the hive which they are intended to inhabit. When they are all in, cover it with a packing or coarſe cloth, which will admit air, and let them remain ſhut up all that night, and the next day. You will ſoon be ſenſible that they are awaked from this ſleep.

The ſecond night after their union, in the duſk of the evening, gently remove the cloth from off the mouth of the hive, (take care of yourſelf) and the bees will immediately ſally forth with a great noiſe; but being too late, they will ſoon return; then inſerting two pieces of tobacco-pipes to let in air, keep them confined for three or four days, after which the door may be left open.

Providence has ordained that inſects which feed on leaves, flowers, and green ſucculent plants, are in an inſenſible or torpid ſtate from the time that the winter's cold has deprived them of the means of ſubſiſtence. Thus the bees, during winter, are in ſo lethargic a ſtate, that little food ſupports them: but as the weather is very changeable, and every warm or ſunny day revives them, and prompts them to return to exerciſe, food becomes neceſſary on theſe ocaſions. Mr. White very judiciouſly obſerves, that a greater degree of cold than is commonly imagined to be proper for bees, is favourable to them in winter. If a ſharp froſt, ſays that experienced gentleman, continues for two or three months, without intermiſſion, you may obſerve, through your glaſs, that the bees are all this time cloſely linked together in cluſters between the combs. If they are not altogether without motion, yet it is certain they ſtir not from their places, while the cold continues, and therefore eat not at all.

A colony of bees therefore placed on the north-ſide of a building will waſte much leſs of their proviſions, than others which ſtand in the ſun; for coming ſeldom forth, they eat little; and yet in the ſpring are as forward to work and ſwarm, as thoſe which had twice as much honey in the preceding autumn. The owner ſhould however examine their ſtate in the winter, and if he finds that inſtead of being cluſtered between the combs, they fall down in numbers on the ſtool or bottom of the hive, the hive ſhould be immediately carried to a warmer place, where they ſoon recover.

Moſt writers on bees have obſerved, that theſe inſects are ſubject to a kind of purging in the ſpring, which is often fatal to the whole hive. Madam Vicat aſcribes this diſtemper to the honey being candied in the hive by the cold. But Columella deſcribes it as an annual diſtemper which ſeizes them in the ſpring, when the ſpurge bloſſoms, and the elm diſcloſes its ſeeds; for that the bees, being allured by the firſt flowers, feed ſo greedily upon them, that they ſurfeit themſelves therewith, and die of a looſeneſs, if they are not ſpeedily relieved. He relates Hyginus's adviſing, in this caſe, to cover the bees with aſhes of the fig-tree; and affirms, that, being enlivened by the warmth of theſe aſhes, the bees will revive in two hours, and go into a hive brought to them. Columella adviſes giving them roſemary and honey diluted with water. Ariſtomachus ſeems to have preſcribed the moſt effectual cure, namely, to take away all the vitiated combs, that is, all the combs in which there are open cells appearing to contain candied honey.

The authors of the *Maiſon Ruſtique*, impute this purging to the bees feeding on pure honey, which does not form a food ſufficiently ſubſtantial for them, unleſs they have bee-bread to eat at the ſame time; and adviſe giving them a honey-comb taken from another hive, the cells of which are filled with crude wax or bee-bread.

The common practice is to feed them in the autumn, giving them as much honey as will bring the whole weight of the hive to near twenty pounds. To this end, the honey is diluted with water, and then put into an empty comb, ſplit reeds, or, as Columella directs, upon clean wool, which the bees will ſuck perfectly dry.

The following directions given for this purpoſe in the *Maiſon Ruſtique*, ſeem to be very judicious. Repleniſh the weak hives in September, with ſuch a portion of combs full of honey, taken from other hives, as ſhall be judged to be a ſufficient ſupply for them. In order to do this, turn up the weak hive, after taking the precaution of defending yourſelf with the ſmoke of rags, cut out the empty combs, and put the full ones in their place, where ſecure them with pieces of wood run acroſs, in ſuch manner that they may not fall down when the hive is returned to its place. The bees will ſoon fix them more effectually. If this method be thought too troubleſome, ſet under the hive a plate of liquid honey, unmixed with water, with ſtraws laid acroſs it, and over theſe a paper pierced full of holes, through which the bees will ſuck the honey, without daubing themſelves. This ſhould be done in cloudy or rainy weather, when the bees ſtir leaſt abroad; and the hive ſhould be covered, to protect the bees from robbers, who might be allured to it by the ſmell of honey.

Another circumſtance which may render it very neceſſary to feed the bees, is, when ſeveral days of bad weather enſue immediately after they have ſwarmed; for then, being deſtitute of every ſupply beyond what they carried with them, they may be in great danger of being ſtarved. In this caſe honey ſhould be given them in proportion to the duration of the bad weather.

But it is not enough to know how to manage bees in all ſeaſons; it will be alſo requiſite to know how to defend them from their enemies; among which hornets and waſps, and eſpecially the ſpecies of waſps which are ſcarcely larger than bees, are very formidable; for they ſeize a bee loaded with honey. If this robbery is committed near the mouth of the hive, they carry off the bee to a place of greater ſafety. Their neſts ſhould therefore be carefully deſtroyed, by pouring plenty of boiling water into them; for this is by much the ſafeſt method.

The field-mouſe is an enemy to be carefully guarded againſt as ſoon as the cold begins to approach: for if it enters at that ſeaſon, it makes dreadful havock. At firſt

it deſtroys the loweſt parts of the combs; but as the weather grows colder, and the bees more torpid, it aſcends up the hive, and ſeizes on the richeſt treaſure: nor does the evil end here: for other bees, ſmelling the honey ſpilt by the mouſe, fall upon the hive, and rob it of what remained; or as ſoon as the warm weather returns, and the bees ſtir about, they are ſometimes ſo diſguſted at the havock made by the mouſe, that they deſert the hive. The only way to guard againſt this, is to prevent its entering into a hive. Whilſt the bees continue in their vigorous ſtate, it dares not attack them: therefore, as ſoon as the cold approaches, the entrance to the hives ſhould be leſſened.

Bees may themſelves be rekoned enemies to bees: for they ſometimes wage cruel wars againſt each other. Their fighting and plundering one another ought chiefly to be imputed, as Mr. Thorley obſerves, either to their perfect abhorrence of ſloth and idleneſs, or to their inſatiable thirſt for honey: for when, in ſpring or autumn, the weather is fair, but no honey can be collected from plants, and is to be found only in the hives of other bees, they will venture their lives to get it there.

Dr. Warder aſſigns another cauſe of their fighting, which is, the neceſſity that the bees are reduced to when their own hive has been plundered, at a ſeaſon when it is too late for them to repair the loſs by any induſtry in the fields.

Sometimes one of the queens is killed in battle. In this caſe, the bees of both hives unite as ſoon as her death is generally known among them. All then become one people: the vanquiſhed go off with the robbers, richly laden with their own ſpoils, and return every day, with their new aſſociates, to pillage their own habitation. This cauſes a throng unuſual for the ſeaſon, at the door of the hive they are plundering; and if the owner lifts it up at night, when all are gone home, he will find it empty of inhabitants; though there perhaps will remain in it ſome honey, which he takes as his property.

When two ſwarms take flight at the ſame time, they ſometimes quarrel, and great numbers are deſtroyed on both ſides, till one of the queens is ſlain. This ends the conteſt, and the bees of both ſides unite under the ſurviving ſovereign.

Robbers make their attacks chiefly in the latter end of July, and the month of Auguſt. They appear to act with caution at firſt, and to procure themſelves an entrance by ſtealth; not pitching boldly like the native bees, and then entering at once in at the door. If they are encouraged by ſucceſs, they return in greater parties, ſometimes all the bees of a hive, and endeavour to force that entrance which they ſought before with ſo much caution. They come in ſuch numbers, as frequently to make thoſe who are not acquainted with theſe ſcenes, miſtake them for new ſwarms: but the number of dead bees ſtrewed on the ground, ſoon convince them of this error. Columella adviſes to kill the queen, if poſſible; but the moſt effectual way to prevent the loſs of bees, as well as of honey, occaſioned by theſe robberies, is, early in the autumn, to leſſen the entrance into the hive, as before directed, ſo as to leave room for only two or three bees to paſs a-breaſt.

In the third claſs of enemies to bees is a ſmall caterpillar, termed the wax-worm, or wax-moth, becauſe of the havock it makes on wax. It is tender in its frame, unarmed and defenceleſs; and yet can ſubſiſt itſelf in the midſt, and at the coſt, of the moſt numerous hive. A few of theſe little caterpillars will deſtroy and break to pieces the combs of a hive, build up new edifices for lodging themſelves in it, and finally force the bees to quit the place.

This inſect is of the ſpecies of the falſe-moth, and is extremely nimble. It is enough for it to get into a hive unawares. It runs ſo very ſwiftly, that it paſſes unperceived, and ſlides into ſome narrow place between the combs, perhaps inacceſſible to bees, there to lay its eggs in ſecurity. This done, it makes its eſcape as well as it can. From each of theſe eggs proceeds a caterpillar, which eſcapes certain death merely by its extreme ſmallneſs, and the quickneſs with which it ſpins and enwraps itſelf in a covering ſufficient to ſecure it from all harm. This covering or tube, is glued to the wax which the caterpillar feeds on, and this inſect lengthens the tube as it eats the wax, till at laſt it ſhuts itſelf up, in order to be transformed into a chryſalis. Several caterpillars, and conſequently ſeveral moths, muſt proceed from the eggs which the males and females engender. Probably the bees deſtroy great numbers of the moths: however, if a ſingle female has an opportunity to lay her eggs, ſhe is ſo exceedingly prolific, that this ſecond brood may quite overſpread the hive. If one of the impregnated females eſcapes out of the hive by means of her great nimbleneſs, ſhe ſeeks out another hive, in which ſhe ſpreads the ſame ſource of miſchief.

The only method of deſtroying theſe pernicious inſects is to take away the infected hive; and after clearing it from the moths, reſtore it to the proper owners, who will now work with greater diligence and reſolution.

The next particular neceſſary to be known, is how to ſeparate the honey from the wax. In order to this, the combs ſhould be laid in a place perfectly ſecure from the acceſs of bees; for otherwiſe the bees would not only carry off much honey, but alſo be extremely troubleſome, by ſtinging the people at work. It is proper to burn cow-dung, or rotten hay, at the doors and windows of this place; becauſe the ſmell of the ſmoke ariſing from thence is ſo diſagreeable to the bees, that it will drive them away. If any bees remain in the comb, they ſhould be bruſhed off with the wing of a fowl into a tub of water, and being afterwards dried in another place, they will fly back to their hive. If the combs are taken out of the hive before the end of autumn, there are generally young bees in them. The parts of the combs in which theſe are ſhould be laid aſide, for they would give a bad taſte to the honey. The bee-bread muſt alſo be ſeparated, and both ſhould be melted with the wax.

Before the combs are laid to drain out their honey, they ſhould be carefully cleaned of every ſort of filth, or inſects. The cruſt with which the bees cover the honey in them ſhould then be pared off with a ſharp, thin, broad knife, and the combs themſelves ſhould be divided through the middle, in ſuch manner as to render the cells open at both ends, that the honey may flow the more freely out of them. The combs ſhould be laid in this ſtate on ſieves, or ſome other contrivance which will afford the honey a free paſſage. It will run quite clear; and the honey thus obtained ſhould be kept by itſelf, as being the pureſt and beſt.

The

The combs, which are but partly filled, and alſo thoſe that were full and have done running, are broken by hand, and the honey in them is ſqueezed out. Some put the broken combs into a ſtrong bag, and then uſe a preſs to ſqueeze the honey out of them; and even warm the broken combs with the help of fire: but neither of theſe laſt conſider that, in both theſe ways, much of the wax paſſes through the bag with the honey, and that the wax being of greater value than the honey, the owner ſuſtains a loſs in that reſpect, beſides that his honey becomes the leſs valuable, in proportion to its being leſs pure. It is true, that great part of the wax thus mixed with the honey ſoon riſes to the ſurface, and may be taken off, eſpecially after the honey is grown hard.

The makers of mead need not be extremely ſollicitous about ſeparating the honey ſo very perfectly from the wax, becauſe, by waſhing the wax in cold water, the honey will diſſolve in the water, and the wax being ſtrained from it by running the water through a coarſe cloth, neither bad taſte nor impurity will be communicated by it to the water, which may afterwards be uſed for making mead. The wax that has been ſkimmed off the honey ſeparated by preſſure, ſhould be waſhed in the ſame manner; becauſe, by this means, no part of the wax will be loſt.

The goodneſs and flavour of honey depend on the fragrance of the plants from which the bees collect it: and hence it is that the honey of different places is held in different degrees of eſtimation. That which is made early in the year is alſo preferred to what is collected in the latter end of the ſeaſon.

In order to obtain the wax in a pure ſtate, what remains of the combs after ſeparating the honey, together with the combs which contain bee-bread and young bees or maggots, is put into a copper with a ſufficient quantity of clean water, which is made to boil over a ſlow fire, and ſtirred frequently with a ſtick. When the wax is melted, it is run through bags, which are put into a preſs, to ſeparate the wax perfectly. The wax runs from the preſs into a veſſel placed underneath, with ſome water in it, to prevent the wax from ſticking to it. What remains after the preſſure may be again boiled in water, in order to obtain more wax from it: and this ſhould be repeated by ſlow boilings, rather than by boiling it ſtrongly at once.

When all the wax is thus ſeparated from the dregs, it is again melted in water, over a very gentle fire, and ſkimmed clean whilſt any ſcum ariſes. It is then poured into veſſels ſuited to give it the deſired form, after previouſly putting into them a little water, to keep the wax from ſticking to them. Theſe veſſels are then carried into a place where the wax may cool gradually. It is found that, the larger the cakes of wax are, the better the wax keeps, and the higher price it brings; alſo, that the more gentle it has been boiled, the better it likewiſe is: for too haſty boiling renders it hard, and this increaſes the difficulty of bleaching it. Whatever filth ſticks to the bottom of the cake is ſcraped off with a knife.

We ſhall conclude this article with a few directions for purchaſing bees; which ſhould always be done in the ſpring, as the dangers of the winter are then over. The ſummer is an improper time for buying them, becauſe the heat of the weather then ſoftens the wax, and thereby renders the combs liable to break, if they are not very well ſecured. The honey too, being then thinner than at other times, is more apt to run out of the cells, which is attended with a double diſadvantage, namely, the loſs of the honey, and the daubing of the bees, whereby many of them may be deſtroyed. A firſt and ſtrong ſwarm, may indeed be carried away in the night after it has been hived.

The hive ſhould be full of combs, and well ſtored with bees. The purchaſer ſhould examine the wax, in order to know the age of the hive. The combs of a year old are white; thoſe of two years are dark coloured, or yellow; and where the combs are black, the hive ſhould be rejected; becauſe old hives are moſt apt to be infected with the moth, and moſt liable to other accidents. For this reaſon, the ſtate of the combs ſhould be examined as high up as poſſible; becauſe the lower parts of the combs may have been cut off, and renewed in the preceding ſummer. It ſometimes, though rarely, happens, that two queens continue to govern ſeparately in the ſame hive; and in this caſe a large comb forms the barrier. Such hives ſhould be rejected, becauſe there is not in them that harmony which is neceſſary for the ſucceſs of the bees.

In order to judge of the ſtate of the hive, it may be raiſed a little in the evening, ſo as to admit a more than uſual degree of cold; for this will drive the bees to the top of the hive, and ſo benumb them, that the next morning there will be no danger of their ſtinging. If any ſuch danger does appear, a pot of lighted charcoal, with ſome linen rags upon it, may be got ready, and held under the hive whilſt it is pulled back in order to be examined.

We may alſo judge of the thriving ſtate of the hive by the following appearances. Bees which are in good condition will get into the fields early in the morning, return loaded, enter boldly, and not come out of the hive in bad weather; for when they do, this indicates that they are in great want of proviſions. They are alert on the leaſt diſturbance; they preſerve their hive free from all filth, or dead nymphs or bees; they are ready to aſſiſt the bees which return loaded from the fields, and to defend the hive againſt every enemy that dares to approach: they make a continual humming noiſe, which increaſes on the leaſt touch. Indeed, by the loudneſs of the humming, we may judge of the ſtrength and progreſs of the hive, and therefore this ſhould be frequently noticed, to enable us to form the better judgment of the preſent ſtate the bees are in. *Columella, lib.* IX. *Maiſon Ruſtique, tom.* I. *Memoires, &c. de la Societé de Berne: Anné* 1764. *Réaumur's Memoires pour ſervir à l'Hiſtoire Naturelle des Inſectes, tom.* V. *Thorley's Enquiry into the Nature, &c. of Bees. Warder's Monarchy of Boes. White's collateral Bee-Boxes. Mill's Eſſay on the Management of Bees.*

BEECH, the name of a well known tree, and of which ſome planters ſuppoſe there are two diſtinct ſpecies: calling the one the mountain or wild beech, and the other the common beech. They alſo ſay, that the wood of the former is whiter than that of the latter; but Mr. Miller aſſures us that there is only one ſpecies of this tree, and that the difference in the colour of the wood ariſes from the difference in the ſoils.

This tree is propagated by ſowing the maſt, which may be done at any time from October to February, only obſerving to ſecure the ſeeds from vermin when early ſown; and, if this be carefully done, the ſooner they

are ſown after they are fully ripe, the better: a ſmall ſpot of ground will be ſufficient for raiſing a great number of theſe trees from ſeed; for if the plants are come up very thick, the ſtrongeſt of them ſhould be drawn out the autumn following, that thoſe left may have room to grow; ſo that a ſeed-bed, carefully managed, will afford a three year's draught of young plants, which ſhould be planted in a nurſery, and, if deſigned for timber trees, at three feet diſtant row from row, and eighteen inches aſunder in the rows.

But if they are deſigned for hedges, to which the tree is very well adapted, the diſtance need not be ſo great; two feet row from row, and one foot in the rows, will be ſufficient. In this nurſery they may remain two or three years, obſerving to dig up the ground between the roots, at leaſt once a year, that their tender roots may the better extend themſelves every way: but be careful not to cut or bruiſe their roots, which is injurious to all young trees; nor ſhould you ever dig the ground in ſummer, when the earth is hot and dry; for by letting in the rays of the ſun to the roots, the young trees are often deſtroyed.

This tree will grow to a conſiderable ſtature, though the ſoil be ſtoney and barren, as alſo upon the declivities of hills and chalky mountains, where they will reſiſt the wind better than moſt other trees; but then the nurſeries for the young trees ought to be made upon the ſame ſoil; for if they are raiſed on good ground, and in a warm expoſure, and afterwards tranſplanted into a bleak, barren ſituation, they ſeldom thrive. The nurſery ſhould therefore be made upon the ſame ſoil, where the plantation is intended, and the plants drawn annually to extend the plantation.

The tree is very proper to form large hedges to ſurround plantations, or wilderneſs quarters; and may be kept in a regular figure, if ſheared twice a year; eſpecially if they ſhoot ſtrong; in which caſe if they are neglected but a ſeaſon or two, it will be very difficult to reduce them again.

The ſhade of this tree is very injurious to moſt ſorts of plants which grow near it, but is generally believed to be very ſalubrious to human bodies.

It delights in a chalky or ſtony ground, where it generally grows very faſt; the bark of the trees in ſuch land is clear and ſmooth, and although the timber is not ſo valuable as that of many other trees, yet as it will thrive on ſuch ſoils, and in ſuch ſituations where few better trees will grow, the planting of them ſhould be encouraged, eſpecially as the trees afford an agreeable ſhade, and the leaves make a fine appearance in ſummer, and continue green as long in autumn as any of the deciduous trees; therefore in parks, and other plantations for pleaſure, this tree deſerves to be cultivated among thoſe of the firſt claſs, eſpecially where the ſoil is adapted to it. *Miller's Gard. Dict.*

The timber is of great uſe to turners for making trenchers, diſhes, trays, &c. and alſo to carpenters for making ſtools, bedſteads, &c. Shipwrights likewiſe often uſe it for the keels of ſhips; and it is eſteemed the beſt wood for firing. The thin lamina, or ſcale of the wood, commonly called paſte-board, is uſed in making band-boxes, hat-caſes, &c.

Beech wood is well known to be ſubject to worms, which ſoon deſtroy it. This worm is ſuppoſed to feed upon the ſap remaining in the wood after it is cut into ſcantlings, and worked up for uſe. If therefore the ſap can, by any means, be extracted, the wood will be much leſs ſubject to decay. Upon this principle, a correſpondent of the authors of the *Muſeum Ruſticum* greatly improved the wood, by laying it a reaſonable time in a pond, and afterwards drying it in the ſhade; by which means the timber when applied to uſe, was at leaſt as good, and as durable as elm. He adds, that by boiling the wood intended for ſmaller works, ſuch as bowls, trenchers, chairs, &c. two or three hours in a copper filled with water, all the ſap will be extracted, the wood will work pleaſanter, be more beautiful when finiſhed, and laſt, without compariſon, longer. *Muſeum Ruſticum, vol.* II. *pag.* 135

BEECH *maſt*, the ſeed of the beech-tree.

This maſt is very good for feeding ſwine; ſo that in ſome counties of England, where there are large woods of beech-trees, the hogs are fed for months together on the maſt only. They thrive prodigiouſly on this food only, ſo that many porkers are killed in a year fatted with beech-maſt, without the aſſiſtance of any other food. It is, however, the better way to take them up, and give them either pollard, barley-meal, or peaſe, for a month or five weeks, when they will be fit for the tub.

But beech-maſt, like acorns, are apt to give the hogs a diſtemper called the garget; which may be effectually prevented, if a few peaſe or beans moiſtened with water, and ſprinkled over with antimony finely powdered, be given them every other day for a fortnight or three weeks. *Muſeum Ruſticum, vol.* I. *pag.* 474.

BEES-NEST, or *birds-neſt*, the ſame with wild carrot. *See the article Wild* CARROT.

BEER, a common and well known liquor, made of malt and hops, and uſed in various parts of Europe, particularly in thoſe where the vine will not flouriſh, and where cyder is ſcarce. *See the article* BREWING.

The grounds, or ſettlings of beer, &c. form a very rich manure.

BEESTINGS, the firſt milk taken from a cow after calving.

If this milk be not taken away clean from the cow upon her firſt calving, it will often make the cow's milk to dry away. Nor ſhould the beeſtings be given to the calf, as it is very apt to ſurfeit. *Liſle's Huſbandry, vol.* II. *pag.* 143.

BEETLE, a wooden inſtrument in the form of a mallet, but much larger, uſed in driving piles, wedges, hedge-ſtakes, &c.

BEETLE, is alſo the name of a flying inſect, of which there are a great variety of ſpecies; but they have all of them caſes over their wings to defend them from hard bodies, which they often meet with when they dig holes in the ground, or gnaw rotten wood with their teeth, to make themſelves houſes or neſts. When they fly they fill the air with a humming noiſe, and, perhaps, greater than that of any other inſect. There are different ſorts of beetles, ſome being large with horns, and others ſmall, and without horns.

BEEVES, a general name for oxen, or black cattle in general.

BEHEN, a ſpecies of chickweed, frequently called ſpattling-poppy. *See* CHICKWEED.

BENT-*graſs*, a ſpecies of graſs common in paſture grounds; there are ſeveral ſorts of this graſs, particularly

larly that called fine bent, for the gathering the ſeeds of which the Society offered a premium. We have given a figure of one of the ſpecies of bent-graſs, on Plate III. Fig. 11.

BERE, or *bear*, a ſpecies of barley. *See the article* BARLEY.

BERNE-MACHINE, the name of an engine for rooting up trees, invented by Peter Sommer, a native of Berne in Switzerland.

A model of this machine was ſent by the Berne Society to the Society for the Encouragement of Arts in London, and from this model the drawing on Plate IV. Fig. 1. was made. The engine conſiſts of three principal parts, the beam, the ram, and the lever. The beam ABC, of which only one ſide is ſeen in the figure, is compoſed of two ſtout planks of oak of three inches thick at leaſt, and ſeparated by two tranſverſe pieces of the ſame wood at A and C, about three inches thick. Theſe planks are bored through with correſponding holes, as repreſented in the figure, to receive iron pins, upon which the lever acts between the two ſides of the beam, and which are ſhifted higher and higher, as the tree is raiſed, or rather puſhed out of its place. The ſides are well ſecured at top and bottom, by ſtrong iron hoops.

The iron pins on which the lever reſts, ſhould be an inch and a quarter, and the holes through which they paſs, an inch and a half in diameter. The poſition of theſe holes is ſufficiently indicated by the figure.

The foot of the beam, when the machine is in action, is ſecured by ſtakes repreſented at G, driven into the earth.

The ram D, which is made of oak, elm, or ſome other ſtrong wood, is capped with three ſtrong iron ſpikes, repreſented at *f*, which takes faſt hold of the tree. This ram is ſix or eight inches ſquare, and a ſlit is cut lengthwiſe through the middle of it, from its lower end at K, to the firſt ferule *a*, in order to allow room for the chain *g h*, to play round the pulley K, which ſhould be four inches thick, and nine inches in diameter. This ram is raiſed by means of the chain *g h*, which ſhould be about ten feet long, with links four inches and three quarters in length, and an inch thick. One end of this chain is faſtened to the top of the beam at C, while the other, after paſſing through the lower part of the ram, and over the pulley K, terminates in a ring or link repreſented Fig. 3. the two ears *m*, *n*, of which ſerve to keep it in a true poſition between the two planks of the beam. In this ring the hook P is inſerted.

The hook is repreſented in profile, Fig. 2. where F is the part that takes hold of the ring. But it muſt be obſerved, that the parts of this machine, repreſented in Fig. 2, 3. are drawn on a ſcale twice as large as the whole engine, Fig. 1.

The hook F, Fig. 2. ſhould be made of very tough iron, as well as the handle D, and the arch E *c*. This handle ſhould be two inches thick at *z*, where it joins to the hook, and the thickneſs gradually leſſen by degrees up to the arch, which need not be more than half an inch thick.

On each ſide of the pin *z*, is a ſemi-circular notch, *x*, *y*, which reſts alternately on the pins, when the machine is worked. The hole D, and the arch *E c*, ſerve to fix a long lever of wood E F, Fig. 2. by means of two iron pins; and by this contrivance the lever is either raiſed or depreſſed at pleaſure, in order to render the working of the machine eaſy in whatever part of the beam the lever may be placed: for without this contrivance the extremity of the lever E F, would, when the handle *d* F was near the top of the beam C, be much higher than men ſtanding upon the ground could reach. It muſt, however, be remembered that the lever is often ſhortened by this contrivance, and conſequently its power leſſened.

The machine is worked in the following method: it is placed againſt a tree, in the manner repreſented in the figure, ſo that the iron ſpikes at *f* may have hold of the tree, and the end of the beam A be ſupported by ſtakes repreſented at G. The iron handle, Fig. 2. is placed in the opening between the two planks of the beam, and the wooden lever fixed to it by means of the iron pins already mentioned. The hook F takes hold of the chain, and one of the iron pins is thruſt into the outer row of holes, by which means the outer notch *x* will reſt on the pin, which will be now the center of motion; and the end of the lever E, Fig. 1. being preſſed downwards, the other notch *y*, Fig. 2. will be raiſed, and at the ſame time the chain, and conſequently the ram. The other iron pin is now to be thruſt into the hole in the inner row, next above that which was before the center of motion, and the end of the lever E, Fig. 1. elevated, or puſhed upwards, the latter pin on which the notch *y* reſts, now becoming the center of motion. By this alternate motion of the lever, and ſhifting the pins, the chain is drawn upwards over the pulley K, and conſequently the whole force of the engine exerted againſt the tree. There is a ſmall wheel at L, in order to leſſen the friction of that part of the machine.

From this account the reader will very eaſily perceive that the machine is nothing more than a ſingle pulley, compounded with a lever of the firſt and ſecond order; and therefore its power may be eaſily computed from the nature of the pulley and lever.

It muſt, however, be remembered, that as the puſh of the engine is given in an oblique direction, it will exert a greater or leſſer force againſt the horizontal roots of the tree in proportion to the angle formed by the machine with the plane of the horizon; and that the angle of 45° is the maximum, or that when the machine will exert its greateſt force againſt the horizontal roots of the tree.

M. N. E. Tſcharner, ſecretary to the Berne Society, obſerves, in a letter ſent to the Society for the Encouragement of Arts, &c. in London, and dated Berne, Jan. 10th 1763, that by repeated experiments with this machine, he has found that the chain *g h*, is ſo far from giving an additional power, that it hinders the play and effect of the engine by its friction; and that when the ram preſſes ſtrongly againſt the beams, the chain is ſqueezed between the beams ſo as to render the upper holes uſeleſs, and prevents the machine from being worked out to its full length; in conſequence of which it is obliged to be removed from its firſt place, and fixed again anew; which neceſſarily occaſions a loſs of time. He alſo found that the ram was too ſhort. He has therefore taken away the chain, and lengthened the ram four feet.

The inconvenience of the chain was immediately ſeen by the Society for the Encouragement of Arts, and therefore the machine at large made by their directions,

was

was conſtructed without it. The ram moved between the two cheeks of the beam, and was puſhed up by the alternate motion of the lever. And that the force of the machine might not be leſſened by the removal of the chain, the lever was made of twice the length of that in the Berne model.

It will be very readily granted, that an engine conſtructed in this manner will be very uſeful in ſaving the labour of men; though very inadequate to the taſk intended, that of throwing down trees. For it ſufficiently appeared from experiments made by the committee of mechanics, that trees above ſixteen inches diameter, eſpecially of oaks or elms, cannot be thrown down with this engine, without the aſſiſtance of cutting their roots.

BEVERAGE, drink, liquor to be drank.

BIENNIAL *plants*, ſuch as continue two years.

BIG, the ſame with bear, or ſquare barley. *See the article* BARLEY.

BIGGE, a pap, or teat.

BILL, an edged tool uſed by huſbandmen in cutting buſhes, &c. It is a kind of hatchet with a hooked point, and a handle either ſhorter or longer, according to the various uſes for which it is intended.

BIN, or BINN, a place where corn, &c. is depoſited.

BIND-WEED, called by ſome *with-wind*, a troubleſome weed, of which there are two ſpecies, the ſmaller and the greater.

The firſt, or ſmaller bind-weed, commonly called gravel bind-weed, is very common upon dry banks, and in gravelly ground in moſt parts of England, and is generally a ſign of gravel lying near the ſurface. Its roots penetrate very deep into the ground, whence it is in ſome countries called devil's guts. It is a very troubleſome weed both in gardens and fields.

The ſecond or greater bind-weed, is alſo a troubleſome weed; but in an open clear ſpot of ground, where the plants are conſtantly hoed down for three or four months, they may be effectually deſtroyed; for when the ſtalks are broken or cut, a milky juice flows out, by which the roots are ſoon exhauſted, and decay; but as every part of the root will grow, this circumſtance renders it a troubleſome weed to deſtroy, where its roots are intermixed with thoſe of other plants. *Miller's Gard. Dict.*

Mr. Liſle, after obſerving that he believes bind-weed propagates itſelf in paſture grounds chiefly by its ſeeds, and by its roots in arable land, becauſe it ſeems to flower too late in corn to ſeed before the corn is cut, thinks the reaſon why it is moſt apt to multiply in clayey ſoils, is becauſe ſuch ground being, in the common practice, ploughed only in winter months, after wheat, for other crops as barley, peaſe, or oats, and not till about September for winter vetches; this tillage cannot deſtroy the roots or ſeeds of weeds like the ſummer fallows for wheat; but, on the contrary, promotes their increaſe, particularly from the off-ſets, or joints of the roots. "I have known, ſays he, in this caſe, clay land folded for barley, and particularly that part of it which, waiting for the folds going over it laſt, was lateſt fallowed, bring up ſuch an increaſe of with-wind, that, though the ſpring and ſummer had been very dry, every ſtem of barley had a with-wind round it. As the fold brought up a crop of this corn, it brought up with each plant its enemy, which would eat it out, pull it down before it could ripen, and thereby prevent the filling of the grain. The crop is alſo greatly hazarded here, after it is cut, from the danger it muſt run by laying in ſwarth, till this weed is withered before it can be carted. Again, near the end of the firſt ſummer, after the firſt year of a crop of hop-clover, which I fed, that is about the beginning of Auguſt, I fallowed the ground for wheat, then dunged the fallows, and ſowed the wheat before Michaelmas. I had a very good crop of wheat; but a with-wind came up to every plant; ſo that had it been a wet and cold ſummer, inſtead of a hot and dry one, as it chanced to be, my corn would have been pulled down and lodged while green in the ear, and in the milk, and could not then have filled in body and flour, but muſt have been of the nature of blighted corn. The increaſe of the with-wind here was, without doubt, occaſioned by laying down this ground only to one ſummer feed after the hop-clover was ſown, when it had borne three or four crops of ſummer corn after its wheat crop; for by the winter ploughing, as I intimated before, the off-ſets of the roots of weeds, and their ſeeds, were propagated. I could not conveniently deſtroy theſe roots or ſeeds by giving the ground a ſeaſonable ſummer fallow in the beginning of June; becauſe I ſhould then have loſt the fruits of my hop-clover crop, by ploughing it in at the beginning of the firſt ſummer: though this would have contributed much to the killing of the with-wind: whereas, by delaying the fallowing three months longer, viz. to the beginning of Auguſt, when the ſun had loſt its ſtrength to burn up the roots and malt the ſeeds, and it was too late for the ground to lie long to a fallow, the dung laid on the fallows, gave new life to the roots and ſeeds. *Liſle's Huſbandry, vol.* II. *pag.* 303.

BIRCH, the name of a tree ſo well known as to need no deſcription. This tree is not much eſteemed for its wood, but however it may be cultivated to advantage upon barren land, where better trees will not thrive; for there is no ground ſo bad, but this tree will thrive in it; for it will grow in moiſt ſpringy land, or in dry gravel or ſand, where there is little ſurface: ſo that upon ground which produced nothing but moſs, theſe trees have ſucceeded ſo well, as to be fit to cut in ten years after planting, when they have been ſold for near ten pounds per acre ſtanding, and the after-produce have been conſiderably increaſed. And as many of the woods near London, which were chiefly ſtocked with theſe trees, have been of late years grubbed up, ſo the value of theſe plantations have advanced in proportion. Therefore thoſe perſons who are poſſeſſed of ſuch poor land, cannot employ it better, than by planting it with theſe trees, eſpecially as the expence of doing it is not great.

The beſt method to cultivate this tree, is to furniſh yourſelf with young plants from the woods, where they naturally grow, and are generally found there in great plenty; but in places where there are no young plants to be procured near, they may be raiſed from ſeeds, which ſhould be carefully gathered in the autumn, as ſoon as the ſcales under which they are lodged begin to open, otherwiſe they will ſoon fall out and be loſt: the ſeeds are ſmall, ſo ſhould not be buried deep in the ground. The autumn is the beſt ſeaſon to ſow them; and in a ſhady ſituation, the plants will thrive better than

than when they are expoſed to the full ſun; for in all places where there are any large trees, their ſeeds fall, and the plants come up well without care; ſo that if the young plants are not deſtroyed by cattle, there is generally plenty of them, in all the woods where there are any of theſe trees. Theſe wild plants ſhould be carefully taken up, not to injure the roots. The ground where they are to be planted, will require no preparation; all that is neceſſary to be done, is to looſen the ground with a ſpade or mattock, in the places where the plants are to ſtand, making holes to receive their roots, covering them again when the plants are placed, cloſing the earth hard to their roots. If the plants are young, and have not much top, they will require no pruning; but where they have buſhy heads, they ſhould be ſhortened, to prevent their being ſhaken and diſplaced by the wind. When the plants have taken root, they will require no other care, but to cut down the great weeds which would over-hang the plants, being careful not to cut or injure the young trees. This need not to be repeated oftener than twice in a ſummer the two firſt years, after which time the plants will be ſtrong enough to keep down the weeds, or at leaſt be out of danger from them.

Theſe may be planted any time from the middle of October, till the middle of March, when the ground is not frozen; but in dry land the autumn is the beſt ſeaſon, and the ſpring for moiſt. The diſtance which they ſhould be planted, is four feet ſquare, that they may ſoon cover the ground, and by ſtanding cloſe they will draw each other up; for in ſituations where they are much expoſed, if they are not pretty cloſe, they will not thrive ſo well.

If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterwards they may be cut every ſeventh or eighth year, if they are deſigned for the broom-makers only; but where they are intended for hoops, they ſhould not be cut oftener than every twelfth year.

The broom-makers are conſtant cuſtomers for birch, in all places within twenty miles of London, or where it is near water-carriage: in other parts the hoop-benders are the purchaſers; but the larger trees are often bought by the turners, and the wood is uſed for making ox-yokes, and other inſtruments of huſbandry.

In ſome of the northern parts of Europe, the wood of this tree is greatly uſed for making of carriages and wheels, being hard and of long duration. In France it is generally uſed for making wooden ſhoes. It likewiſe makes very good fuel.

In ſome places theſe trees are tapped in the ſpring, and the ſap drawn out to make birch wine, which has been recommended for the ſtone and gravel, as is alſo the ſap unfermented. The bark of the birch-tree is almoſt incorruptible. In Sweden the houſes are covered with it, where it laſts many years. It frequently happens, that the wood is entirely rotten, and the bark perfectly ſound and good. *Miller's Gard. Dict.*

The beſt method of obtaining the ſap of the birch-tree for making wine, &c. is to bore a hole ſlanting upwards with a middle-ſized augre to a moderate depth in the tree, and to faſten a bottle to the orifice, by which means a large quantity of the ſap may be ſpeedily procured. Or many gallons in a day may be gathered from the boughs of the trees by cutting them off, leaving their ends fit to go into the mouths of bottles, and ſo by hanging many bottles on ſeveral boughs, the liquor will diſtil into them very plentifully.

The ſeaſon for this work is from the end of February to the end of March, whilſt the ſap riſes, and before the leaves ſhoot out from the tree; for when the ſap is forward, and the leaves begin to appear, the juice, by a long digeſtion in the branch, grows thick and coloured, which before was thin and limpid. Nor will the ſap diſtil either in the night, or in cold weather while the north and eaſt winds blow; but very well and freely, when the ſouth-weſt winds blow, or the ſun ſhines warm.

The liquor is beſt that proceeds from the branches, having been a longer time in the tree, and thereby better digeſted, and acquiring more of its flavour than if it had been extracted from the trunk. *Mortimer's Huſbandry, vol.* II. *pag.* 406.

In order to have enough of this liquor to ſet about making wine with it, many trees ſhould be tapped at the ſame time, ſo that a ſufficient quantity of ſap may be obtained in a few days; for it will not keep long, without a tendency to putrefaction. To prevent this, ſome authors adviſe ſetting that which is firſt drawn in bottles, or other proper veſſels, in the ſun, till the reſt be ready, and to put into it a hard toaſt of rye-bread cut thin, to make it ferment. But as it is neceſſary to mix with this juice either ſugar or raiſins, in order to give it a body, to enable it to undergo a regular fermentation, which alone can render it fit for keeping, and for want of which it is that this wine is ſo apt to burſt the bottles into which it is put, that firſt fermentation will certainly be found hurtful. When therefore the huſbandman has not a ſufficient number of trees to obtain ſap enough for his purpoſe in two or three days, the moſt adviſable way will be to put the ſap into very ſweet veſſels, and place them in a cool cellar; for it will keep there perfectly ſound, for a much longer time, eſpecially if it be covered with oil, or bunged up cloſe.

The proportion of ſugar may be varied according to the taſte and intention of the brewer: but, in general, a pound of ſugar is thought to be the proper allowance for a gallon of this liquor. The ſap and ſugar muſt be thoroughly united by a heat juſt ſufficient to make them boil; but the long boiling, which is generally adviſed, can anſwer no good purpoſe: on the contrary, it will render the liquor leſs diſpoſed to ferment kindly, and likewiſe deprive it of a conſiderable part of the peculiar fragrance and flavour of the tree from whence it was taken. It ſhould therefore be carefully remembered, that the ſole purpoſe of boiling this liquor is, to make a thorough diſſolution of the ſugar in it. Some people ſubſtitute honey inſtead of ſugar; in this caſe a quart of honey is eſteemed equal to a pound of ſugar. With regard to various ſpices ordered by different writers, they muſt be left to the taſte and option of the maker.

It is generally found neceſſary in order to ferment this liquor, to put into it a little yeaſt, a bit of dough, or a thin toaſt of leavened bread; after which it is treated in all reſpects like other vinous liquors. See the articles FERMENTATION, and WINE.

It is ſaid, that in the North, where large birch and plane trees are frequent, their ſap is obtained in ſuch plenty as to be uſed for brewing, inſtead of water, and that it makes equally ſtrong beer with much leſs malt. Dr. Tong, in the Philoſophical Tranſactions, N° 46. ſays, that one buſhel of malt brewed with this liquor will make as good ale,

ale, as four buſhels with common water. He thinks the ſap of the ſycamore the beſt for brewing; becauſe it is very ſweet, and, at the ſame time, very wholſome.

BIRD-GRASS, *or* FOWL-MEADOW-GRASS, a very excellent graſs imported from Virginia, by the late Peter Wych, Eſq; and has been cultivated with ſucceſs by Mr. Roque. The Rev. Dr. Elliot of New-England, in his Eſſays on Field-Huſbandry, tells us, that it acquired this odd name from its being brought into a piece of poor meadow at Dedham, by ducks and other wild water-fowl. We have given a figure of this valuable graſs on Plate IV. Fig. 4.

As Mr. Roque is the only perſon that has ſucceſsfully cultivated this ſpecies of graſs, we ſhall give our readers his own account of it, which he ſent in a letter to the Society for the Encouragement of Arts, &c.

"In the month of March, 1764, I received from the late Peter Wych, Eſq; the chairman of the committee of agriculture in the Society for the Encouragement of Arts, &c. an ounce and a half of the ſeed of a ſpecies of graſs called bird-graſs. He obtained it from Virginia, where it grows, though it is not a native graſs. The intention of putting it into my hands was, in order that I ſhould cultivate it, and be thence able to form a judgment whether it might have any peculiar properties not found in our graſſes, that would render it an advantageous article of culture here. He had, himſelf, conceived a very high opinion of it, by the information he had gained concerning it, from the country whence it came; and intended, as ſoon as he ſhould have due proof from experiment, of what he hoped, to bring it before the Society for the Encouragement of Arts, &c. who had, with public-ſpirited zeal, entered very minutely into the conſideration of the means of improving paſtures. Being very ſolicitous to acquit myſelf of the truſt, I carefully preſerved this little treaſure till the month of April, which I thought might be a fit time to ſow it. Not being acquainted with the particular nature of this graſs, I prepared the ground for it, in the ſame manner I ſhould have done for a flower-bed: raking it with a wooden rake. I did this as I was willing by every means to ſecure its coming up: but ſuch care would not have appeared in the leaſt neceſſary, had I known its great hardineſs, and force of vegetating power, as I have done ſince.

"At the time I expected the bird-graſs to riſe from my ſeed, I found the weeds and common graſs coming up very thick: ſo that I could not diſtinguiſh the deſired kind from theſe intruders; particularly the poa-graſs. Being a ſtranger, as I before ſaid, to the appearance of the bird-graſs, I thought it the beſt way to weed out the other graſs and herbs which I knew, and to let what I could not diſtinguiſh to be ſo, remain in the ground: and my eagerneſs was ſo great to perceive whether the bird-graſs was come up, that I went almoſt every hour to look after it. I diſcovered it at laſt, in about a month from the time of its being ſown, by its having a deeper green hue than is commonly ſeen in our graſſes: and I tranſplanted it as ſoon as I imagined it would bear moving, into ſome of the ſame kind of ground, as that on which it had been raiſed: having firſt turned it up and cleared it from weeds. The ſize of this piece of ground was about twenty rods: part of it a little gravelly, and the other part of it moory land. I ſoon perceived the bird-graſs grew better on the gravelly than on the moory part of the ground. That on the gravelly being of a better colour and ſweeter than that on the moory; which was pale and yellow. And with reſpect to the moory ground itſelf, one part was moiſter than the other, and the bird-graſs grew better on the drier ſide than on the wet. The graſs, however, looked well all the ſummer, and in the month of September following, I began to gather the ſeed, and proceeded in it till October. The quantity of the ſeed was above twelve pounds.

"The firſt year the graſs did not grow to above two feet and an half high: but the ſecond it roſe to be four feet high. On the 14th of June of that year, being 1765, I meaſured out ten rods of this graſs, and cut it. Three days after I weighed the product of this ten rod, herb and ſeed together; and they amounted to twelve hundred pounds. The tenth of Auguſt following, the ſame graſs was again grown to the height of two feet eight inches, and was a ſecond time fit to cut for hay: but I did not cut it; becauſe I wanted a ſecond crop of ſeed: which I obtained in the beginning of October; and it proved a much greater crop than the former. About this time a good deal of rain fell, which occaſioned me no ſmall ſhare of trouble in drying the graſs, and turning the little cocks. I then firſt remarked that ſhoots were made from almoſt every joint, in conſequence of the moiſture; but from ſome more than others: and of theſe many were of a finger's length. Had I not ſuffered this graſs to ſtand, that I might have the ſeed, I am ſatisfied I could have mowed it thrice in the year; but wanting to collect as great a quantity as I could of the ſeed, I have not yet actually tried that experiment. I am very confident, however, that this kind of graſs may be brought to afford eight tons of hay per acre in the year: and any perſon who may entertain doubts of the reaſonableneſs of this ſuppoſition, may have them cleared up by ocular proof, if they will take the trouble to call on me; as great numbers of gentlemen have already done, to their entire ſatisfaction in this point. The latter end of May, and the beginning of June, will be a proper time for ſuch inſpection; as this graſs, being a forward kind, will be fit to cut at that ſeaſon.

"This graſs has a peculiar quality, different from what is found in any other kind I ever knew before; which is, that it hath very ſhort joints, and that every joint ſends out ſhoots, which ſtrike root whenever they touch the ground. On taking a full-grown plant of the graſs out of the ground, it will be found, moreover, capable of being divided into twenty ſmaller roots or off-ſets, proper to be again planted: and theſe off-ſets, though taken thus from the root, even in the beginning of July, will bear ſeed the ſame year. If, likewiſe, when this graſs is ready to be mowed, there ſhould happen to be much rain, no damage will enſue on waiting a month for fair weather. Becauſe, as this graſs is conſtantly ſending out ſhoots at every joint, it always keeps freſh; and does not wither, nor rot at the bottom, as other graſſes do: but, on the contrary, it continues green, even till the ſeed is ripe: which is certainly a very ſingular property, and of great conſequence.

"The goodneſs of this kind of graſs may alſo be very obviouſly inferred from the following particular. When I had ſowed it, which was in the month of April, 1764, I had, as I have above declared, only one ounce and a half of ſeed: but betwixt that time and the preſent, I have found ſuch a ſurprizing increaſe, that I have collected from the ſucceſſive crops of this ounce and a half, as much ſeed as has ſown two hundred and fifty acres of land; and

have

have beſides, as much by me at preſent, as will ſow one hundred acres more.

" I ſhall not dwell any longer on the commendation of this graſs, than only to ſay, that it has every quality requiſite to make good hay. That it is eaſily propagated, and from a very ſmall portion of ſeed. That it is not ſubject to rot, or fail in patches, as moſt other kinds of graſs do. That it is a beautiful green at all times, and conſequently affords a moſt pleaſing verdure, when ſown in ſight of any houſe, or made part of any proſpect. And, laſtly, that the produce of hay from it is extremely great, being much more than any other kind of true graſs will yield. Of the truth of all this many perſons can witneſs, who have, on ſeeing the real trials reſpecting it, given the greateſt encomiums on it: I ſhall therefore proceed now to offer ſome directions for its culture.

" The ground on which the ſeed of this kind of graſs is intended to be ſown, is to be prepared in the manner that is proper for lucern: that is, it ſhould be well ploughed and harrowed; and cleared, as much as poſſible, from all weeds, in the ſame way as is done for barley. When the ground is well mellowed and ſweetened, the ſeed may be ſown: the quantity of which may be about one pound and a half per acre; and the time of doing it, from March to April.

" Before the bird-graſs ſeed be ſown, it will be proper to ſow as much barley or oats, as will afford half a crop: and ſuch barley or oats being harrowed in, the pound and half of bird-graſs ſeed ſhould be ſown over it: after which, in general caſes, the ground is only to be rolled the firſt opportunity when it is dry. But if the ſoil be ſandy or dry, it may be proper to give it a very light harrowing.

" This kind of graſs cannot be well ſown without ſome corn. Becauſe it is of ſo fine and delicate a nature, at its firſt coming up, that the weeds would overpower and choak it at that time: or a great expence would be neceſſary for clearing them away by hand. But when this graſs is ſo mature, as to be in the ſtate of a paſture, or fit to cut, it grows ſo cloſe and thick, that if a handful of money was thrown up over it, none would, when fallen, I am certain, reach the ground.

" As to the nature of the ſoil proper for the culture of bird-graſs, almoſt every kind will do very well for it; except, as has been obſerved before, ſuch as is too wet or moory; and this is one of the good properties of this graſs, becauſe few kinds flouriſh much on dry gravelly ground.

" This is a juſt account of the obſervations and experiments I have hitherto made on this valuable graſs; and they ſeem ſufficient to juſtify me, in endeavouring to render it known to the public, as an object worthy their attention."

BIRD'S-NEST, the name of a weed, otherwiſe called wild carrot. *See Wild* CARROT.

BISHOP, a little ſpotted beetle, commonly called the lady-cow, or lady-bird.

BISHOPING, a cant term made uſe of by horſe-jockies, implying the unfair practices they make uſe of to conceal the age of an old horſe, or the ill properties of a bad one.

BIT, *or* BITT, the iron part of a bridle, put into a horſe's mouth.

BLACK, a colour in horſes, eſteemed very beautiful, eſpecially when they are of a jet ſhining black, and well marked, without having too much white: for as a great deal of white, eſpecially when it ſpreads round their eyes, and a great way up their legs, adds nothing to their beauty, ſo neither does it add any thing to their goodneſs. The Engliſh black horſes have more white about them than the black horſes of any other country. The Spaniſh, Arabian, Dutch, and Daniſh horſes, ſeldom have much; though a ſtar or blaze, and ſometimes a white muzzle, and one or more of the feet tipped with white, always looks beautiful and lively, and is ſo far from being a diminution of the goodneſs of a horſe, that moſt think it an addition, from an opinion that horſes without marks are generally ſtubborn and ill-conditioned. Some black horſes have brown muzzles, are browniſh on their flanks, and between their hips. Theſe are often called black browns, as they are not a perfect black, but approach near to the colour of a tawny black hound; ſome are of a lighter colour about their muzzles, and are called mealy-mouthed horſes; and of theſe ſort are the pigeon-eyed horſes, which have a white circle round their eye-lids, and their fundaments often white. Thoſe that partake moſt of the brown, are generally the ſtrongeſt in conſtitution. *Gibſon on Horſes, vol.* 1. *pag.* 46.

BLACK-GRASS, a ſpecies of graſs in America, of which the following account is given by the late Dr. Elliot of New-England.

" We have, ſays that worthy writer, in a letter to Mr. Mills, an excellent ſort of graſs in our ſalt-marſhes. It thrives beſt, and grows largeſt, in thoſe meadows which border on tide-rivers, and have the greateſt mixture of freſh-water. Where the water is very ſalt it is not apt to fix and ſpread; but will remain ſhort and poor. It is very tender, and cuts as eaſily as garden cives, grows thicker and taller than the common ſalt-marſh graſs, and affords from two to three tons of hay to the acre: but it is a ſlow grower, after it has been cut. Its ſeeds are ſmall, like thoſe of tobacco. The colour of this graſs is a very deep green, which renders it ſo conſpicuouſly different from every other kind, that it is univerſally known by the name of black graſs.

" This ſpecies introduced itſelf long ſince the ſettlement of New England. Our firſt planters knew nothing of it; nor has it yet travelled very far ſouth-weſt. Its firſt appearance in this colony was on a marſh at Saybrook, to which an old boat was brought down Connecticut river, by a great flood, and there caſt up. This inclined me to think, that it was originally an inland graſs, which happened to ſuit with ſuch ſalt marſhes as are well ſupplied with freſh water; and what confirms me in this opinion is, that a perſon in the town of Killingworth, where I reſide, having cleared a ſwamp far diſtant from ſalt water, and afterwards ſent into this freſh meadow, cattle, which had been foddered with hay of the black graſs, had there in a ſhort time (undoubtedly by means of its ſeeds carried thither in the dung of theſe cattle) a fine growth of this very graſs, which has ſince not only eſtabliſhed itſelf, ſpread, extended, and, like a conqueror, beaten out the natural graſs; but looks as flouriſhing in that freſh meadow, as any growing on a ſalt-marſh.

" I have a large tract of peat meadow, in which no graſs ſeeds will grow. I deſign to try the ſeeds of this black graſs in that dead freſh meadow, ſince the other ſorts which I have tried do not ſucceed. What encourages me to do this, is my having introduced it into a once uſeleſs, worthleſs moraſs, worſe indeed than nothing, though of conſiderable extent, for I was obliged

to be at the expence of fencing it, for the ſake of other land. It was quite over-run with reeds, buſhes, and brakes.

" Between this land of mine and a creek of ſalt water, intervened three meadow lots belonging to other perſons. I obtained leave of the owners to cut a ditch ſix feet wide through their ground, and carried this ditch to the upper end of my land, where ſeveral croſs ditches were then dug, to invite in, and retain the ſalt water. The gaping mouths of theſe numerous ditches ſoon occaſioned a ſtrong indraught of ſalt water, and, in time, converted the main ditch into a proper tide creek. The ſalt water thus introduced has done wonders. It has not only killed the trees, buſhes, brakes, and levelled great inequalities, but has alſo introduced the black graſs, and thereby rendered an acre of that land, which was not worth any thing before, now worth thirty-five pounds of our currency.

" The ſalt water in its paſſage through my neighbours grounds has alſo done them great ſervice, by introducing this black graſs; and all this with ſmall expence." *Mills's Huſbandry, vol.* III. *p.* 416.

To this account of the black graſs given by doctor Elliot, we ſhall add the following, tranſmitted in a letter from that gentleman's ſon-in-law, the reverend doctor Gale.

" Its (the black graſs) early ſpring and growth, its lively green, its great produce, the preference given to it by cattle, when diſtributed promiſcuouſly with ſalt graſs for their food; its rendering the turf of mirey, looſe, dirty meadows, firm and ſolid, and its extraordinary quality when improved for paſture in the ſpring and ſummer, raiſed its reputation, and endeavours were uſed to propagate it: but it proved very ſullen and uncertain in its growth; growing only where it liſted, from the ſeed promiſcuouſly ſhed, and wafted about by the tide which overflowed the meadows.

" It is obſerved to grow and flouriſh well near the banks of rivers, which admit the ſalt water, and even in flat or low meadows, which are in ſome meaſure overflowed every tide by the ſalt water: but theſe low meadows muſt alſo be of that kind only, where there is a courſe of freſh water when the tide is out: ſo that a mixture of both freſh and ſalt water ſeems to be neceſſary for its prolific vegetation.

" It grows largeſt and beſt in reedy and ruſhy coves, or arms of the ſalt meadows, which are a little higher than the general level of the ſalt marſh, which are not commonly overflowed by the flux and reflux of the tides, which lie at ſome diſtance from ſalt creeks or courſes of ſalt water, and which are watered by freſh ſprings riſing from the banks, or adjoining uplands.

" I have ſeen ſeveral ſuch meadows which flouriſh remarkably with this ſort of graſs, though but lately brought under culture: I am credibly informed, that eight acres of ſuch a cove produced this year thirty-two tons of black graſs in an adjoining townſhip.

" The black graſs is not near ſo much impregnated with ſalt as the common graſs is, when both of them grow together; and the dew which adheres to the black graſs is freſh, when that on ſalt graſs is highly impregnated with ſalt.

" It thrives beſt on a clay or ſtrong loam. The natural turf ſhould be broken, and the ſeed, after being mixed with freſh cow dung, ſhould be ſpread, and faſtened in by treading, that it may not be carried off by the water: or it may be propagated by tranſplanting the turf taken from a black graſs meadow, by which means it will be made to ſpread a pace.

" It will alſo grow where ſalt water never reaches. I have ſeen it growing on moiſt upland, and the turf has been ſo firm, that it was hard work for ſix oxen to plough through it.

We ſhall only add, that the above gentleman has juſt ſent the Society for the Encouragement of Arts, &c. a conſiderable quantity of the ſeed of this black graſs; and that they have diſtributed it to a number of gentlemen, in order to their ſowing it on proper ſoils; ſo that there is great reaſon to hope that this valuable graſs will ſoon be as well known in England, as it is now in America.

BLACK-LAND, a name given to a particular ſort of clayey ſoil, which is rather a grey than a true black. But however pale it may be when dry, it always blackens by means of rain; and when ploughed up at thoſe ſeaſons, it ſticks to the plough ſhare; and the more it is wrought, the muddier and duſkier coloured it appears.

Theſe ſorts of lands when ſomewhat fat, yet porous, light, and ſufficiently tenacious, are good both for corn and graſs; but as they are moſtly in bottoms, ſo the wetneſs of them often ſpoil them for corn; but where they are dry, they are extraordinary fruitful, eſpecially for barley; they will bear alſo good wheat upon an erch crop: but if they are ſo very rich, that you fear lodging of the corn, you may, if a deep mould, plant them with liquorice, or ſow them with hemp, woad, cole, rape ſeed, madder, or ſome other rich commodity, that beſt agrees with ſuch land; and afterwards with corn, when ſome of the fertility is abated. The natural produce of theſe lands is commonly thiſtles, docks, and all ſorts of rank weeds and graſs. It will bear excellent clover. The beſt manure is chalk, lime, dung, &c. *Mortimer's Huſbandry, vol.* I. *pag.* 75.

BLACK-LEGS, a name given in Leiceſterſhire to a diſeaſe frequent among the calves and ſheep. In Staffordſhire they call it the wood-evil.

It is a white jelly, and ſometimes a bloody jelly, ſettling in their legs, from whence it has its name of blacklegs, and often in the neck between the ſkin and fleſh, which will make them carry their necks awry. If it falls on the joints they overcome it; but if on their bowels they die, nor is there any cure. *Liſle's Huſbandry, vol.* II. *pag.* 134.

BLACK OATS, a ſpecies of oats greatly cultivated in the northern parts of England, being eſteemed a very hearty food for horſes. *See the article* OATS.

BLACK THORN, a ſpecies of buſhes well known, and much uſed in making fences, &c.

It is not reckoned quite ſo good for fences as the white thorn, becauſe it is apt to run more into the ground, and is not ſo certain of growing; but then the buſhes are much the beſt, and moſt laſting of any for dead hedges, or to mend gaps: nor are cattle ſo apt to crop them as the other. They will grow on the ſame ſort of ſoil with the white thorn; but the richer the mould is, the more they will proſper. *Mortimer's Huſbandry, vol.* I. *pag.* 5.

BLADE, the ſpire of graſs, or green ſhoots of corn.

BLADE, alſo ſignifies the ſharp or ſtriking part of a weapon or inſtrument.

BLAIN, a diſeaſe to which cattle are ſubject in the ſpring of the year. Some think it is occaſioned by a little red worm which the cattle lick up. It often occaſions a bladder as large as a hen's egg under the tongue, and when this happens, the beaſt may be cured by breaking the bladder, and rubbing it with ſalt.

Others impute the diſeaſe to a ſudden riſing of the blood, and may be known by the beaſt's eyes running with water; and as the diſtemper advances, its eyes will ſwell, and, if bled under the rump, the blood will feel hot. In this caſe the following drench is recommended. Take a pennyworth of Engliſh liquorice, and an equal quantity of Engliſh anniſeeds, turmeric, long pepper, horſe-ſpice or diapente, all ground fine, and juſt boiled up in a quart of ſtrong beer; but if the heat of the blood indicates that the diſtemper proceeds from a hot cauſe, the horſe-ſpice ſhould be omitted. It is added, that if the bladder cannot be found under the tongue, the bum-gut ſhould be raked, where it will be found in the back. If a knife be run through the ear of a beaſt near the root, it will, according to the report of experienced graziers, prove a certain cure in this diſtemper, provided it be done before the beaſt falls. *Liſle's Huſbandry, vol.* II. *pag.* 127.

BLAST, the ſame with blight. *See* BLIGHT.

BLAZE, a white mark in a horſe's face.

BLEA, that part of a tree which lies immediately under the bark, or between that and the hard wood, and is the firſt progreſs of the alteration of the bark into wood, by the natural growth, and ſtrengthening of the fibres.

While the blea remains any thing ſoft, and retains ſomewhat of the nature of bark, it may maintain a feeble vegetation; but when it is grown abſolutely hard and woody, it can no longer contribute to carry on that operation.

BLEEDING, an operation frequently neceſſary among all kinds of cattle, particularly horſes; and conſiſts in opening a vein by means of an inſtrument called a fleam.

Thoſe horſes that ſtand much in the ſtable, and are full fed, require bleeding more than thoſe that are in conſtant exerciſe; but eſpecially when their eyes look heavy and dull, red and inflamed; or when they look yellow or inflamed in their lips, and inſides of their mouths; when they ſeem hotter than uſual, and mangle their hay. Theſe are all indications that require bleeding, and likewiſe to lower their diet till they have more exerciſe.

Young horſes ſhould be bled when they are ſhedding their teeth, which is a relief to them, and removes thoſe feveriſh heats, to which they are ſubject at that time.

The ſpring is always a proper ſeaſon for bleeding, becauſe their blood is then more luxuriant than at other times; and in ſummer it is often neceſſary to prevent fevers, always chooſing the cool of the morning, and keeping them cool the remaining part of the day.

Some bleed their horſes three or four times a year, or even oftener, by way of prevention. Theſe take a very ſmall quantity at a time, not exceeding a pint, or a pint and a half, only to give a kind of briſker motion to the blood, and by that means to preſerve or render it more thin and fluid, and to prevent its ſtagnating in the ſmaller veſſels, which indeed is the firſt beginning of almoſt all diſeaſes; but how far this ſucceeds, can only be known to thoſe who have practiſed it a ſufficient time. There is, however, this inconvenience from frequent bleeding, that it grows into a habit, which, in ſome caſes, cannot be eaſily broken off without hazard; and ſome horſes have been known to become weak from frequent bleeding, while others have had their necks ſo full of ſcars, that they are apt to inflame and feſter every time they are bled, which is always troubleſome, and often ends with the loſs of the vein. And therefore to prevent ſuch accidents, thoſe who bleed horſes ſhould not confine their operation to one place of the vein, as they generally do, but uſe themſelves to open it higher or lower as they ſee occaſion; and if they meet with any difficulty in bleeding in the neck veins, the plate veins, or any other large veins, that can be made to run a full ſtream, will equally anſwer the ſame end.

But the caſes that require bleeding moſt, are colds, fevers of almoſt all kinds, falls and bruiſes, which are ſometimes dangerous to horſes, becauſe of their great weight. Hurts and wounds of the eyes, ſtrains in hard riding, or drawing, and all other accidents where a ſtagnation of the blood may be ſuddenly expected, or where the ſmall veſſels may be broke, and the blood extravaſated. Thoſe horſes that refuſe their food after riding, or any ſort of work, require to be bled more frequently than others, to prevent fevers, and inward inflammations of the lungs, the liver, or any of the principal viſcera. Nor is it leſs neceſſary to bleed horſes at graſs, when the purgation is over, and they begin to gather fleſh, or at any other time, when they look heavy about their eyes, for that is a proper indication for bleeding; and ſome rank paſtures require more bleeding than others.

There are alſo other indications that require bleeding by way of prevention, viz. when any epidemic diſtemper prevails among the horſes; at ſuch times the ſound ones may be bled, to keep them, if poſſible, from being infected; and if the contagion continues, it may not be amiſs to repeat the bleeding once in two or three months, or oftener; but in ſmall quantities, for the loſs of too much blood may be hurtful in ſome times of contagion. It is likewiſe neceſſary to keep ſound horſes from the unſound, or to remove them into places where the infection has never ſpread itſelf. *Gibſon on the Diſeaſes of Horſes, vol.* I. *pag.* 218.

BLEYME, an inflammation in an horſe's foot, occaſioned by blood putrified in the inner part of the coffin towards the heel, between the ſole and the coffin-bone.

There are three ſorts of bleymes; the firſt, bred in ſpoiled, wrinkled feet with narrow heels, are uſually ſeated in the inward or weakeſt quarter; the ſecond, beſides the uſual ſymptoms of the firſt, infects the griſtle, and muſt be extirpated, as in the cure of a quitter-bone. *See* QUITTER-BONE. The third is occaſioned by ſmall ſtones, or gravel, between the ſhoe and the ſole. For the cure they pare the foot, let out the matter, if any, and dreſs the ſore like the prick of a nail.

BLIGHT, a general name for various diſtempers incident to corn and fruit trees.

M. du Hamel treats that part of this ſubject which relates to corn in a very maſterly and inſtructive manner; dividing what we generally call blights into the following ſpecies, viz. empty ears, parched and ſhrivelled corn, glazed corn, abortive or rickety corn, barren corn, and fallen or lodged corn. The reader will find each under its proper articles, as EMPTY EARS, &c.

BLIND, deprived of the ſenſe of ſight.

Moon BLIND, or *lunatic*, a diſeaſe to which horſes are ſubject, the ſymptoms of which are no other than the fore-runners of cataracts, and generally end in blindneſs.

Signior Ruini, ſays that experienced writer Mr. Gibſon, and moſt other foreign writers, both French and Italian, in treating the diſeaſes of horſes, have all of them reckoned the moon-blind ſymptoms as a peculiar diſeaſe of the eyes, without having any relation to a cataract, which they have conſidered a-part, as another diſeaſe of the eyes, which ſhews they built more on books than experience. But from many years obſervation, I do not remember I have ever ſeen a cataract bred in the eyes of any other horſes than thoſe which were called lunatic, or moon-blind. The Arabians were the firſt that aſcribed ſo much to the moon in the diſeaſes of the human body: and after the decay of learning all over Europe, their ſuperſtitious notions were ſo firmly riveted, and ſo univerſally prevailed, that they could not be eaſily exploded, even by the ableſt phyſicians, till the modern diſcoveries in natural knowledge made way for more ſolid improvements in the medical art; and therefore it is no wonder, that the firſt writers on the ſubject of farriery, notwithſtanding ſome of them were men of learning, ſhould fall in with all the common ſuperſtitions that had ſo long prevailed, and had ſo great an influence on the practice of phyſic.

Theſe writers have deſcribed this diſtemper as appearing at certain times of the moon, coming ſometimes at the new-moon; ſometimes at the full; and ſometimes in the wane of the moon; that it ſometimes returns once in three months; ſometimes once in two months, and in ſome not above once in ſix months: that the eyes look ſo clear when the diſtemper abates, that it is impoſſible to ſee any imperfection in them. But theſe obſervations are very liable to exception; for any one who has the leaſt knowledge of the eyes, muſt needs ſee, that when the diſtemper is the moſt abated, and the eye the moſt clear, it ſtill ſhews a remarkable weakneſs, and upon full trial, the ſight will be found defective. Neither could I perceive that the eyes were affected by any of the moon's periods, ſo as not to vary, unleſs by mere accident. And therefore theſe obſervations are neither of any great uſe to the knowledge of the diſtemper, nor to lead us into a right method of curing it when it happens.

I have already taken notice, that the ſymptoms which appear in the moon-blind horſes, are, for the moſt part, no other than the prognoſtics of breeding cataracts. Theſe ſymptoms generally make their firſt appearance, when a horſe is turned five, coming ſix, at which time one eye becomes clouded, the eye-lids ſwoln, and very often ſhut up; and, for the moſt part, a thin viſcid water runs, from the diſeaſed eye, down the cheek, which is generally more or leſs in proportion, as the eye and eye-lids happen to be more or leſs ſwelled and inflamed; and in ſome conſtitutions, the inflammation is ſo great, and the humour ſo ſharp and corroſive, that it ſcalds and fetches off the hair wherever it comes. The veins of the temples and under the eye, along the ſide of the noſe, are alſo turgid and full: others run but little; nor is the humour very ſharp.

This diſorder is apt to come and go, till the cataracts are perfect and ripe, and then all pain and anguiſh, and the ſoreneſs and running of the eyes, go off with blindneſs, when the horſe is between ſeven and eight years old, this being about the time when moſt horſes are ſpread and come to their full growth; ſo that from its firſt appearance to its completion, is generally about two years, or two years and a half, during which time, ſome horſes have the returns of the diſorder, not only more frequently than others, but the ſymptoms alſo are more ſtrong and violent. In ſome the eye is not much diſturbed above a week, when it clears up again, and returns to its former ſtate. In ſome horſes the eye continues bad a fortnight or three weeks. In others a month or longer, before the diſorder goes off; and the time of the return, ſo far as I could obſerve in many horſes, was always uncertain, and could not be fixed to any period of the moon, as many have imagined, being ſometimes ſooner, ſometimes later, according to its predominancy, or according to the treatment a horſe meets with from his farrier and keeper. Some have their returns once within the ſpace of two or three months; ſome within the ſpace of four; and, with the greateſt care and pains, the diſorder ſeldom keeps off above five months, without a relapſe.

This is uſually the caſe of thoſe moon-blind horſes, which have their eyes ſtrongly infected with a hot ſharp humour, that ſhuts them up with ſwelling and inflammation. But there is another kind of moon-blindneſs, which is alſo the fore-runners of cataracts, where no humour or weeping attends the eye. It is never ſhut up or cloſed, as in the caſe above deſcribed, but will now and then look thick and troubled, at which time the horſe ſees little, and, perhaps nothing diſtinctly. Here the eyes always appear ſunk and periſhing, though the cataracts do not become ſo ſoon complete, as in thoſe that are full, and where a humour is predominant; nor is it unuſual in this caſe for one eye to eſcape, whereby a horſe will retain ſight to guide him, ſo as to render him fit for common drudgery.

The cauſes of this diſtemper are various, and when it proceeds from a natural defect in the eyes, it may no doubt be hereditary; but in a horſe that has naturally good eyes, and yet turns moon-blind, it is uſually owing to ſickneſs, or ſome other malady that has terminated in the eyes; though we ſeldom ſee horſes turn moon-blind and breed cataracts, but where the eyes are naturally in fault. Theſe eyes are, for the moſt part, faulty, that are very large and prominent, or very flat, ſmall, and ſunk; both which defects in the eyes of horſes are liable to blindneſs, though they differ in their manner; and therefore colts, that have large eyes, that run abroad, always feed with their heads downwards, and are continually expoſed to the ſun in hot weather, may eaſily contract an habitual weakneſs in their eyes, eſpecially as the blood and juices of all young animals are naturally of a viſcid and balſamic texture, and thence may be the more eaſily retarded in the veſſels of the eye, which are exquiſitely fine. Theſe cauſes produce weakneſs and relaxation in the eyes, and this ſtill increaſes till the blood is in that ſtate, which we may reaſonably ſuppoſe to continue till a horſe is done ſpreading, and turned ſeven, for then the cataracts generally grow complete. On the other hand, when the eyes are flat, and lie deep within their orbits, the ſurface of the eye being alſo flattiſh, the rays of light falling directly upon the pupil, and theſe not being ſufficiently refracted, as they are in thoſe eyes that are more convex, or of a rounder make, muſt needs weaken the eye, affect the optic-nerve, and conſequently weaken the tone of the muſcles. And, perhaps, this may be the reaſon why the eyes periſh and decay, while the cataracts are growing.

The ſigns of this diſtemper may, in ſome meaſure, be deduced from what has been already obſerved; viz. ſwelling and inflammation of the eyes alternately, ſometimes one

one eye, and ſometimes the other, with a running of a thin watery ſerum, which is often ſo hot and ſcalding, as to fret off the hair. In others the eyes run but little, and ſome not at all; but look deadiſh, ſunk, and periſhing. In all moon-blind horſes, the eyes are ſometimes tolerably clear, at other times thick and muddy, of a wheyiſh colour, or a duſky yellow; and when this happens, a moon-blind horſe ſees but little, and when he is brought out into the light, he takes little notice of any perſon or object that is near him, but always looks upwards, with his head raiſed, lifts his feet high, and ſets them down with fear. Though in this diſtemper the humour ſhifts from one eye to the other by turns, and at ſome intervals ſeems to go off, yet when the eyes of ſuch horſes are at their beſt, they look weak, and with a deadneſs, and when any ſuch horſe has his head held up, the weakneſs of the muſcles, and of the whole eye, is eaſily perceived.

When this diſtemper happens to horſes that have large full eyes, reſembling thoſe of a calf, and when the humour continues by long periods, and the returns are frequent, there is great danger of blindneſs. If the eyes be of a moderate ſize, well formed, and the periods or returns of the diſtemper ſhort; if the horſe ſees perfectly when the humour goes off, and the eyes in thoſe intervals look clear, the horſe may recover. When the humour attacks one eye without changing to the other, there is alſo hopes of a cure, at leaſt, of ſaving one eye. But when the eyes look flat and depreſſed, and decay gradually, it is generally the fore-runner of blindneſs; for in this caſe the nerves and muſcles of the eyes are affected, and the cataracts always grow in the progreſs of the diſtemper. Here, however, as in the preceding caſe, when the diſtemper ſeizes only one eye, the other may be ſometimes ſaved, and when this happens, the remaining eye generally grows ſtronger when its fellow is gone. But when the diſtemper proceeds from a violent cold, as ſometimes happens, whereby we often ſee the eyes ſwoln, and quite ſhut up, though the horſe may be threatened with blindneſs by ſeveral returns, yet by good management it may ſometimes be prevented, and the eyes recover. Nor does the diſtemper always prove incurable, when the eyes are darkened with a yellow cloud, provided the eye be not naturally bad, and the above ſymptom of long continuance. In all caſes of moon-blindneſs, the moſt promiſing ſigns of a recovery are when the attacks come more ſeldom, and their continuance grows ſhorter: or when the inflammation and ſwelling in thoſe eyes that are naturally full and large abates. Alſo, when the eyes, that looked ſunk and periſhed, grow more plump and full; and when in either the cornea looks clear and tranſparent, without muddineſs, and the horſe looks more attentive to his way, and goes on without much fear or ſtartling; all theſe are promiſing ſigns, and with good and careful management he may recover.

The moſt difficult part ſtill remains to be treated of, namely, the method of curing this diſorder, for few moon-blind horſes eſcape; and when it is hereditary, or the eyes naturally defective, it is not adviſable for any one to be at much expence and trouble to ſave them, as there is great reaſon to fear he will meet with a diſappointment. We, however, ſometimes ſee moon-blind horſes, at leaſt ſuch as have many of the ſame ſymptoms, recover and do well, even beyond expectation.

If the eyes are large, full, ſwoln, and inflamed, the horſe ſhould be bled at proper intervals ſometimes in the neck, and ſometimes backward, to make a revulſion. But where the eyes appear ſunk or periſhing, bleeding is often pernicious. After bleeding, for thoſe that are full and run a thin ſharp water, make a ſtrong tincture of roſes in the following manner:

Take two drams of red roſe-buds, either freſh or dried, infuſe them in half a pint of boiling water in the manner of making tea; when it has ſtood to be cold, pour off the infuſion, which will be of a reddiſh colour.

In four ounces of this tincture diſſolve half a dram of ſugar of lead, and waſh the horſe's eyes, and all over his eye-lids, with a piece of ſponge, or a clean bit of rag, twice a day. If the matter digeſt and thicken, which uſually happens before it abates, add to the whole quantity of this tincture about two drams of honey (which will diſſolve in the fluid, by holding the phial near the fire, and ſhaking it) and uſe it as before. At the ſame time, if the parts near the eye be hot, and the veins over the face, and along the ſide of the noſe be turgid and full, bathe thoſe parts frequently with the beſt vinegar, verjuice, or vinegar of roſes, till the heat and running of the eye abates, the veins ſink, and become leſs apparent, and the eye begins to look clear. In the mean time ſome lenient mild purges may be adminiſtered, ſuch as the following:

Take lenitive electuary and cream of tartar, of each four ounces; ſyrup of the juice of buckthorn berries, two ounces; mix theſe with white wine and water, warmed, about a pint, and give it faſting. Or,

Take lenitive electuary and cream of tartar, of each four ounces; Glauber's purging ſalts, three ounces; the ſolutive ſyrup of roſes, two ounces; to be mixed with white wine and water, or warm water-gruel.

Either of theſe may be given to moon-blind horſes. The latter is rather the more mild and cooling, and exceeding proper if the horſe be fat and full of blood, and will work ſo gently, that it may be repeated twice a week, till the eye becomes clear, and attains its uſual brightneſs.

The horſe ſhould have feeds of ſcalded bran while theſe lenitives are given him, and he may have moderate exerciſe, or may be made uſe of in any kind of eaſy buſineſs; for theſe draughts, for the moſt part, work off in about two hours. But as the blood, in all theſe caſes, is generally fizy, and as this diſpoſes young horſes to frequent returns of the diſtemper, it is therefore neceſſary to adminiſter ſuch things as may attenuate the juices, and preſerve them in a more fluid ſtate. Theſe are called alteratives, becauſe their property is gradually to alter the ſtate of the blood. The following has been often uſed, in this and many other caſes, with great ſucceſs:

Take the fineſt ſuccotrine aloes, half an ounce, or ſix drams; cream of tartar half an ounce; freſh jallap, in fine powder, and ſalt of tartar, of each one dram; make the whole into a ball, with a ſufficient quantity of oil of amber, and roll it in liquorice powder.

One

One of theſe balls may be given every week, in the manner of a common purge, with ſcalded bran, and his water milk warm. The firſt day it will work plentifully by urine, and the day following both ways; but no more than juſt to empty his guts, unleſs when there is a foulneſs, by reaſon of a redundant ſlime or greaſe; when it will often work very powerfully two or three days, without the leaſt diminution of the horſe's ſtrength, or loſs of fleſh. Theſe alterative purges ſhould be continued for a month or ſix weeks, and after omitting another month to begin again; in all which time the horſe may be kept in any common buſineſs, except hunting, going journies, or any other laborious exerciſe.

In the intervals between the purges it will be proper to give him an ounce of crude antimony every day, made into a fine impalpable powder, in one of his feeds, which may be continued for three months or longer. But if the horſe be of value, inſtead of crude antimony, he may have powders compounded of native cinnabar, or cinnabar of antimony, and gum guiacum, equal parts, giving him an ounce every day, till he has taken two or three pounds; and after an interval of about three months, to proceed in the ſame method till the eyes look ſtrong and clear, and the horſe ſhews no ſigns of blindneſs, or any defect in his ſight or weakneſs in his eyes. Several gentlemen have followed this method with good ſucceſs, where the eyes have been full, and no way periſhed. A pound of guiacum wood boiled in three gallons of water till it is reduced to two, is a cheap remedy, and may be profitably adminiſtered to horſes of ſmall value. It promotes perſpiration, dries up ſuperfluous humidity, ſtrengthens the ſolids when relaxed, and ſweetens the blood. It may be given a quart or two every day, in a horſe's water, and will have a good effect to prevent moon-blindneſs, where it is not hereditary, nor proceeds from a natural defect in the eye.

But when the eyes are ſunk and periſhing, and the eye-brows are pinched at their inner corners next the noſe; when there is little or no inflammation or running, except a more than ordinary moiſture in the caruncle, or haw of the eye, or where there is no moiſture at all, as we often find in many moon-blind horſes: wherever theſe ſymptoms are, a method of cure is required quite different from the preceding. For as we ſuppoſe here the nerves of the eye to be affected, and the ſupplies of the arterial blood by that means denied; therefore, wherever the fault may be, whether originally in the blood or in the nerves, it is neceſſary, in either caſe, to adminiſter ſuch things as not only attenuate the blood, but may cauſe a greater derivation thereof to the eye: ſo that the moſt likely way to ſucceed is by the proper uſe of mercurials; and theſe ſuch as are the moſt efficacious, and at the ſame time the moſt ſafe. But firſt of all let the horſe have the laſt mentioned purge given him by way of preparation, and when the operation is over, which will be mild and gentle, the following ball may ſucceed:

> Take mercurius dulcis that has been often ſublimed and dulcified, two drams; make it into a ſmall ball, with a ſufficient quantity of conſerve of red roſes, and wheat flour.

Let this ball be given early in the morning faſting, and tie up the horſe from eating two or three hours after it; then let him have a feed of ſcalded bran, with warm water, or warm gruel to drink; which regimen ought to be continued the whole time he is under this courſe of mercurial and purging phyſic; cold water and other cold drinkables, being ſomewhat unſafe at ſuch a time. The mercurial ball may be repeated every other day, in the morning, till the horſe has taken three or four. If his mouth grows tender, which may poſſibly happen, if he be not of a pretty ſtrong conſtitution, he muſt be fed with water gruel for two or three days, till that ſymptom wears off. At the ſame time the purge may be repeated once or twice, and the following eye-water applied outwardly to both his eyes, if both be weak and diſordered:

> Take crude ſal ammoniac, cleaned from the black ſcurf that is uſual on the outſides of the cakes, two drams; diſſolve it in a pint of warm water, or the above tincture of roſes; and add to it a gill of ſpirit of wine, or the beſt brandy, ſhaking them together in a quart bottle.

The eyes may be bathed all over with this mixture, twice a day, or it may be uſed in the manner of a fomentation, by wringing cloths out of it, and applying them warm over the eyes. This will act as a ſtimulus, and may alſo help to thin and rarify the gummy juices, and bring new ſupplies of nouriſhment to the periſhing eyes. At firſt it may cauſe a little ſmarting; but after uſing it a day or two that ſymptom goes off, and if the eyes grow more plump and full, there will be hopes of a recovery, at leaſt of ſaving one eye; and therefore the beſt way upon this proſpect is to proceed in the ſame method, after a month's interval, and ſo on, as you find encouragement. And in all the intervals, the powders mentioned above, ſhould be given in all his feeds, or the decoction of guiacum in his water.

Some take up the eye veins to prevent blindneſs, but without diſtinction, whether the eyes are full with redundant humours, or ſunk and periſhing. In the latter caſe the taking up the veins may poſſibly be of ſervice, becauſe by that means the eyes may be better ſupplied with its proper nutritive juices; but this too is uncertain, becauſe the fault may be in the nerves, or the diſtemper may proceed from ſome original configuration of the eye, which may be defective, and then ſuch operations are like to prove fruitleſs. But the taking up the veins where the eyes are full, muſt, for the moſt part, prove hurtful, by cutting the channels which ſhould convey the blood and juices from thence in the courſe of circulation, and conſequently increaſe the diſtemper, inſtead of abating it. In this caſe the taking up the arteries might be of ſome ſervice; but this is an operation that only perſons well ſkilled in the anatomy of a horſe, ſhould preſume to undertake, and in the end might perhaps be uncertain.

The cutting out the haw is another operation uſually performed on moon-blind horſes. The haw is a ſwelling or ſpunginеſs of the caruncle or fleſhy ſubſtance in the inner corner of the eye next the noſe, and when it is ſoaked with too much moiſture and humidity it ſwells and turns ſpungy. The membrane to which it adheres alſo grows thick, and ſpreads itſelf ſo as to cover a conſiderable part of the eye, but ſeldom reaches ſo far as to cover any part of the pupil. The ligament which runs along the verge of this membrane becomes horny;

horny; and when it riſes to this ſtate, it compreſſes the eye-ball like a hoop, and by its continual preſſure cauſes conſtant pain, and increaſes all thoſe bad ſymptoms that are the fore-runners of blindneſs. Haws grow ſometimes in eyes that are not naturally bad, after colds and ſurfeits; but moon-blind horſes are ſeldom without them: and wherever this ſymptom appears, that the haws grow large and ſpungy, and derive a drain of humours upon the eye, the operation becomes neceſſary, and is performed by taking hold of the membrane with a ſmall hook, and cutting off ſo much of the caruncle as looks moiſt and ſpongy, with part of the membrane and griſtle that cauſe a preſſure on the eye. When this operation is well performed, it does great ſervice, and often recovers horſes that are not ſubject to cataracts; and even in this caſe it makes the eyes look ſomething better, and helps to protract the blindneſs, but will not prevent it when it is hereditary. This is an eaſy operation, and what almoſt every farrier pretends to; but they are apt to cut off too much of this ſubſtance, and by that means weaken the eye, and forward the blindneſs, inſtead of preventing it. The proper application after cutting out the haw, is honey of roſes, or rather tincture of roſes, with a little honey diſſolved in it. But if the eye continue ſtill to abound with moiſture, after the haw is extirpated, and threatens a freſh fungus, the caſe may be deemed bad; and then it will be neceſſary to blow into it a ſmall quantity of burnt alum and fine loaf ſugar, equal parts, once or twice a day; or one part of white vitriol, and two parts of ſugar; and in ſome caſes it may be touched with the blue vitriol-ſtone, or the lunar cauſtic; but theſe violent ſymptoms ſeldom happen, and when they do, we may ſuppoſe the blood to have a very bad diſpoſition: ſo that it will be hardly worth while to attempt a cure, conſidering both the length of time, and the uncertainty of ſucceſs. *Gibſon on the Diſeaſes of Horſes, vol.* I. *pag.* 326.

BLINDNESS, a want of ſight. The ſheep in ſome parts of Wiltſhire are troubled with a blindneſs, and are cured by anointing their eyes with gooſe dung. *Liſle's Husbandry, vol.* II. *pag.* 212.

BLISTERING *ointment*, a name given by farriers for a ſort of charge or plaſter for raiſing a bliſter in horſes. There are various preſcriptions for making this ointment, but the following is equal to any yet known:

Take nerve and marſhmallow ointment, of each two ounces; quickſilver one ounce, thoroughly broke with an ounce of Venice turpentine; Spaniſh flies powdered, a dram and a half; ſublimate one dram; oil of origanum, two drams.

BLOOD, a red liquor circulating through the veins, arteries, and other veſſels of animal bodies; and ſerving for the ſupport of life, and nouriſhment of all their parts.

Blood is an excellent manure for almoſt any ſort of ſoil. Mr. Evelyn tells us, "that after the battle of Bagnam fields, in Devonſhire (where lord Hopton obtained a ſignal victory) the blood of the ſlain fertilized the land, which had been ſown with corn a little while before, to ſuch a degree, that moſt of the wheat ſtalks of the enſuing crop bore two, three, four, nay ſeven, and ſome even fourteen ears; a thing almoſt incredible. The owner of the land ſeeing how miſerably it had been trodden down, thought of reſowing it; but was diſſuaded from that deſign (perhaps to make the experiment) and had the above-mentioned ſurprizing crop." The huſbandman ſhould, therefore, be careful to procure the offals of the ſhambles, where they are to be had, as they will prove an excellent manure.

BLOOD-*letting*. *See the article* BLEEDING.

BLOOD-*ſpavin*, a ſwelling and dilatation of the vein that runs along the inſide of the hock, forming a little ſoft ſwelling in the hollow part, and is often attended with a weakneſs and lameneſs of the hock.

The cure ſhould be firſt attempted by bathing the part twice a day with vinegar or verjuice; or let it be fomented with a decoction of oak bark, pomegranate, and alum, boiled in verjuice, binding over it, with a roller, a woollen cloth ſoaked in the ſame, which will contribute greatly to ſtrengthen all weakneſſes of the joints, and, if early applied, will frequently remove the diſorder: but if by theſe means the vein is not reduced to its uſual dimenſions, the ſkin ſhould be opened, and the vein tied with a crooked needle and waxed thread paſſed underneath it, both above and below the ſwelling, and the turgid part ſuffered to digeſt away with the ligatures: for this purpoſe the wound may be daily dreſſed with turpentine, honey, and ſpirit of wine, incorporated together. *Bartlet's Farriery, pag.* 279.

BLOSSOM, a general name for the flower of plants, but more eſpecially of fruit-trees.

BLOSSOM, or *peach coloured horſe*, is one that has white hairs intermixed all over with ſorrel and bay hairs.

BLOW-MILK, ſkimmed, or ſloten milk: that from whence the cream is blown off.

BLOWN, ſwelled or hoved. *See the article* HOVED.

BLUE-BALL, a name given to the cone-wheat in Somerſetſhire, from the dark colour on the edge of the huſks of the chaff, which cover each grain, and the falling off of the awns when ripe; ſome of the ears having awns, and others none. *See the article* CONE-WHEAT.

BLUE-BOTTLE, *knapweed, matſellan*, or *centaury*, the name of a weed abounding in many corn lands, flowering in July, and ripening its ſeeds in autumn.

Mr. Miller ſays the corn-blue-bottle is an annual plant; but Mr. Ray and Mr. Liſle think its root is perennial; becauſe, as the latter obſerves, it not only puts forth new buds every ſummer at the root for the growth of the next year, but ſeems alſo not to ſeed early enough, before the corn is cut, to propagate itſelf by its ſeed in corn lands, in which it moſt abounds, eſpecially in a gravelly ſoil.

BLYME, the ſame with bleyme. *See* BLEYME.

BOAR, the male ſwine. *See the article* HOG.

BODY *of a horſe*, the material part or ſubſtance of a horſe, uſually called his carcaſe. *See the article* CARCASE.

BOG, properly ſignifies a quagmire, covered indeed with graſs, but not ſolid enough to ſupport the body; in which ſenſe it differs from moors or fens only as a part from the whole. *See the articles* MOOR and FEN.

Mr. King, in his account of the bogs in Ireland, publiſhed in the Philoſophical Tranſactions, Numb. 170, imputes the true cauſe of them to want of induſtry.

"The ſprings, ſays he, with which Ireland abounds, are generally dry, or near dry in the ſummer time, and graſs and weeds grow thick about the places where they burſt out. In the winter, they ſwell, run, and ſoften, and looſen all the earth about them. The ſward or

ſcurf

ſcurf of the earth, which conſiſts of the roots of graſs, being liſted up and made fuzzy by the water in the winter, as I have ſeen it lifted up a foot or two at the head of ſome ſprings, is dried in the ſpring, and does not fall together, but withers in a tuft, through which ariſes new graſs; which is alſo lifted up the next winter. By this means the ſpring is more and more ſtopt, and the ſcurf grows thicker and thicker, till at firſt it makes that which we call a quaking bog; and as it grows higher and drier, and the roots of the graſs, and other vegetables become more putrid, together with the mud and ſlime of the water, it acquires a blackneſs, and grows into that which we call a turf bog. I believe that when the vegetables rot, the ſaline particles are generally waſhed away with the water, as being apt to be diluted in it. The oily, or ſulphureous, are thoſe which chiefly remain, and ſwim on the water; and this is that which gives turf its inflammability.

"I muſt confeſs, that there are quaking bogs cauſed otherwiſe. When a ſtream or ſpring runs through a flat, the paſſage, if not tended, fills with weeds in ſummer, trees fall acroſs it, and dam it up: then, in winter, the water ſtagnates farther every year, till the whole flat is covered. Afterwards, a coarſer kind of graſs ſhoots up, peculiar to theſe bogs. This graſs grows in tufts, its roots conſolidate together, and its height increaſes every year; inſomuch, that I have ſeen it as tall as a man.

"This graſs rots in winter, and falls on the tufts, and with it the ſeed, which ſprings up the next year, and ſo ſtill makes an addition. Sometimes the tops of flags and graſs are interwoven on the ſurface of the water, and this becomes by degrees thicker, till it lies like a cover on the water: then herbs take root in it, and by the matting of their roots it becomes very ſtrong, ſo as to bear a man. I have gone on bogs which would riſe before and behind, and ſink where I ſtood, to a conſiderable depth; under which was clear water.

"As a farther proof that want of induſtry is the principal cauſe of bogs, Mr. King obſerves, that the higheſt mountains in Ireland being full of ſprings, and uninhabited, are over-run with bogs, as well as the plains, becauſe no care is taken to clear the ſprings.

"Ireland, continues he, abounds in moſs more than, I believe, any other kingdom. This moſs is of divers kinds, and that which grows in bogs is remarkable. The light ſpongy turf is nothing but a congeries of the threads of this moſs, as I have frequently obſerved, before it be ſufficiently rotten. The turf then looks white, and is light. I have ſeen it in ſuch quantities, and ſo tough, that the turf-ſpades could not cut it. In the north of Ireland, they call it old-wives tow, being not much unlike flax. The turf-holes, in time, grow up with it again; and all the little gutters in bogs are generally filled with it. To this I chiefly impute the red or turf bog; and from the ſame cauſe even the hardened turf, when broken, is ſtringy; though there plainly appear in it parts of other vegetables: and I am almoſt, from ſome obſervations, tempted to believe, that the ſeed of this bog-moſs begets heath, when it falls on dry and parched ground. However, the moſs is ſo fuzzy and quick growing a vegetable, that it greatly ſtops the ſpring, and contributes to thicken the ſcurf, eſpecially in red bogs, where I remember to have obſerved this moſt particularly."

A flat ſpot of ground, lower than the level of an adjoining river or lake, may alſo give riſe to a bog; for when that part is filled up by the ſlime and earth brought from the ſurrounding grounds, and the rotten plants and animals, which are buried in it, have choaked it up, it will become a bog; and then the water will continue to flow into it from the river or lake, eſpecially when either of theſe is ſwelled by a fall of rain, or melting of ſnow. Theſe waters may alſo ſometimes have this effect, without a communication above ground, by ſoaking thro' a ſandy or gravelly ſoil.

Another cauſe of bogs have frequently ariſen from the fall of a number of trees, which, being neglected, have neceſſarily occaſioned a ſtagnation of the water brought down from higher grounds; ſo that the earth and other ſoil conveyed with it, have of courſe remained among the fallen wood, and given birth to a moſſy ground, which, it is plain from hence, is not an original ſoil. Coarſe graſs, and weeds which cattle will not eat, ſpring up in theſe places, and die there, after ſhedding their ſeeds, which, being prevented from rotting by the bituminous acid in the moſſy-water, produce new plants; ſo that, this being repeated every year, an annual addition is made to the depth of the moſs.

Draining of BOGS. Among the many and great inconveniences which neceſſarily ariſe from bogs, Mr. King mentions the following, as cogent reaſons why every endeavour ſhould be uſed to bring them, firſt to a leſs hurtful ſtate, and afterwards to a condition in which they may be of ſervice to mankind.

"The fineſt and ſmootheſt plains, which generally ſhould be meadows, are often covered with uſeleſs, too often with really pernicious bogs. Theſe bogs are a great deſtruction to cattle, the chief commodity of Ireland. In the ſpring time, when the cattle are weak and hungry, the edges of the bogs are commonly cloathed with graſs, and the beaſts, in venturing to get it, fall into pits or ſloughs, where they are either drowned, or, if they are found, hurt, and often maimed, in the pulling out. The fogs and vapours which ariſe from theſe places are commonly putrid, ſtinking, and very unwholſome: for the rain which falls on them, ſtagnating upon their ſurface, and in their hollows, than which there is hardly any ſubſtance, equally ſoft, more impenetrable by water, corrupts there, and is exhaled by the ſun; ſo that, very little of it running off, it muſt of neceſſity affect the air. They corrupt other water, both in its colour and taſte: for the water which ſtands in the pits, or lies on the ſurface of the bog, is tinctured by the reddiſh-black colour of the turf; and when a ſhower comes, ſo as to make theſe pits overflow, the water which runs from them tinges all it meets, and gives its colour and ſtench even to many rivers. The only advantage derived from any bog, is turf for fuel. It makes a tolerable ſweet fire, in the common way of uſing it; and is, when charred, perhaps, the ſweeteſt and wholeſomeſt thing that can be burnt, fitter for a chamber, and for conſumptive people, than either wood or coal.

"All the inconveniences of our bogs, continues Mr. King, may be remedied, and they may be made uſeful to us, by draining: for I never obſerved one bog without a fall ſufficient to drain it, nor do I believe there is any. The great objection againſt this improvement is the expence: in which I cannot but think the people are often terrified without ſufficient cauſe. One trench

will

will drain many acres in quaking bogs, which, when dry, are generally meadow, or the beſt grazing ground. Every red bog has about it a deep, marſhy, ſloughy ground, which is called the bounds of the bog. A deep trench round ſuch a bog keeps out cattle, and turns the bounds into good meadow. I remember a red bog of ſixty acres, which a gentleman reduced to good grazing ground, worth three ſhillings an acre, for twenty-five pounds, which is leſs than three year's purchaſe. In all improvements of this kind, gentlemen ſhould conſider, that what they lay out goes by degrees, ſo that they ſcarcely feel it; that it goes among their tenants, whom it helps to enable to pay their rent; that they do a work of charity in employing the poor; and that they at the ſame time contribute to both the ornament and general profit of the kingdom.

The deep trench before mentioned, round a red bog, not only drains and improves the bounds of the bog, as I ſaid before, but goes a great way towards drying the bog itſelf. It ſerves likewiſe as a common ſink, into which all the drains vent themſelves. Theſe drains ſhould be cut ſo as to croſs the little ſloughs that run in the bog. The firſt drains ſhould not be above two or three feet deep, or wide: for the bog is ſo ſoft, that deep trenches will not ſtand, but fill up again. When the ſurface of the bog is cut in little trenches, ſuppoſe at twenty, thirty, or forty perches diſtance, it will ſoon be ſo dried that cattle may graze on it all the ſummer. A year or two after this, by which time the bog will be ſomewhat dry towards the ſurface, the drains may be made ſix feet wide, and as deep as the ſoftneſs of the bog will permit. This will certainly make the bog uſeful for grazing; and at the end of another year or two, an attempt may be made to cut one or two of the trenches down to the bottom of the bog; for till that be done, I do not reckon the bog ſecured. A gentleman may oblige all his tenants to cut their turf in theſe trenches, and likewiſe have his own cut there." *Philoſophical Tranſactions, Numb.* 170.

Small bogs may be turned to very good account by planting them with oſiers, willows, and alders: but where the extent is conſiderable, this object becomes of too little conſequence. Draining will be however neceſſary before they can be improved any other way; as a previous ſtep towards which, it will be neceſſary to examine from whence their too great quantity of water ariſes, and what retains it. When the cauſes are known, their effects will be the more eaſily removed.

The ſources from whence the too great quantity of water proceeds, may either be without or within the bog. This is eaſily diſcovered by the greater quantity of water in one place than in another, and obſerving that the water ſpreads from thence, even under the ſurface, as through a ſponge.

If the water from without comes from neighbouring grounds, it is uſually kept off by a ſurrounding ditch, made large enough to contain the quantity that may at any time flow down, and by extending that ditch to the moſt convenient outlet, according to the declivity of the ground. If the bed of gravel or ſand through which the ſprings within the bay run, be cut quite through, the ſource of thoſe ſprings will certainly be deſtroyed; and if that bed be only opened in digging this ſurrounding ditch, the water will ſo readily diſcharge itſelf thereby, that the ſprings will probably be dried up.

Before any drain be made in the bog itſelf, an exact level of the ground ſhould be taken; and when the too great moiſture proceeds from a ſpring or ſprings within the bog, a large ditch ſhould be made, beginning at the loweſt part of the bog, where an outlet can be had, and continued from thence to the ſpring. If the bog be firm enough to bear it, this ditch ſhould be dug down to the very bottom of the bed on which the peat or moſs is formed, which in caſe of ſprings, is always gravel or ſand: for otherwiſe the water would force itſelf a paſſage in another part, and ſo make it neceſſary to extend the ditch thither. If there be more ſprings than one, the main ditch muſt be extended to each of them. In all caſes, the ſureſt way is to dig the ditch, where it can be done, at leaſt a foot deeper than the ſpring lies. Between the principal ditches cut in the bog, there ſhould be ſmaller, emptying themſelves into thoſe larger, to carry off the remnant of ſtagnating water, and to preſerve the ſurface dry. Care ſhould be taken not to lay the earth dug out of any of theſe ditches too near their ſides, leſt its weight ſhould make them fall in.

Bogs are generally higher than the land about them, and higheſt in the middle; the chief ſprings that cauſe them being generally about the middle, from whence they extend by degrees, and puff up the earth in ſuch a manner, that perſons are often apt to think the ſprings lie deeper than they really do. A ſure way to know whether the ditch be deeper than the ſpring, is, to obſerve whether the water comes in at its bottom, or through the ſides. The width of the main ditch ſhould be proportioned to its depth; and both will, in a great meaſure, depend upon the quantity of water neceſſary to be drained. In general, it ſhould widen progreſſively from its head to its outlet, becauſe the quantity of water in it will be conſtantly encreaſed. The ſides of the ditch ſhould always be dug either more or leſs ſloping, according to the ſoil. If the ground be very looſe and light, and conſequently very liable to fall in, it will ſometimes be neceſſary to make a ſlope ſo great, that the top of the ditch will be four times as wide as its bottom. If the ſoil be ſtiffer, the ſlope may be leſs; but no ditch ſhould ever be dug quite perpendicular.

If a deep trench be cut through a bog, the original ſpring will be found, vaſt quantities of water will iſſue from it, and the bog will ſubſide. Mr. King ſays that he was informed that the bog at Caſtle Forbes, where this was done, ſubſided thirty feet, a fall which ſeemed indeed incredible: but he found by computation that it could not be leſs than fifteen.

Mr. Elliot's contrivance for draining a bog, or what he calls a ſhaking meadow, containing about forty acres, deſerves to be mentioned, for the ſingularity as well as the uſefulneſs of the invention. The ſurface of this ground, over-run with cran-berry vines and wild graſs, ſeemed to be only a ſward of their roots laid over a pappy mud, and was deemed ſo poor that nobody would rent it. At the ordinary outlet of this meadow, there was a ſufficient fall, but very rocky, ſo that it was neceſſary to dig four or five feet to take advantage of it. In March, when this gentleman went to make the outlet dain, the torrent of water was ſo great, that nothing could be done in the uſual way. He therefore ordered a tree to be felled a croſs the brook, and pieces of plank, the upper ends of which reſted againſt the tree, to be driven down aſlant into the mud. The chinks and crevices of theſe

planks were then closely stopped with tow, by which means the water was shut into the meadow. The trench or main ditch was then worked at in the day, and the water let out at night, till the drain was completed. When the weather grew sufficiently warm, and the meadow was a little settled, cross ditches were cut, one on each side, and another in the middle, and, so far as they extended, the meadow soon became firm and dry. "Some, adds Mr. Elliot, are deterred from such an undertaking as that of draining their land, by reason of the great charge. They terrify themselves without reason. When I was about to cut my main drain, some thought it impossible; others, that it would cost, at least, an hundred pounds. The place was full of rocks, some of which we dug up, others, were broken with steel wedges, and others were blown up with powder. The whole expence did not exceed twenty pounds." *Essay* I. *on Field Husbandry, p.* 7.

When the ditches and trenches are finished, great care must be taken to keep them in good and lasting condition, lest all the labour bestowed upon them should be lost. There are different ways of doing this. If the ditches are left open, they must be well cleansed from weeds and mud, twice every year, once in the spring, and once in the autumn. It will also be right to drive in from space to space, along the inside of their banks, strong stakes of oak or alder, to strengthen them, and keep them from falling in. Willows, which delight in a watery soil, may be advantageously planted upon these banks, which their roots will help to keep up and bind.

If a bog be so entirely surrounded with high grounds, as not to have any declivity whatever, by the help of which its waters may be drained off, ditches must then be dug round it, to receive the water from the neighbouring hills, and a very large pond must be made in the middle or lowest part of the bog itself, for its waters to run into; to facilitate which, large trenches should be cut from the surrounding ditches to this pond, and channels communicating with these trenches across different parts of the bog. The number and size of which will depend on the greater or less wetness of the ground. When the water is thus collected, engines must be used to raise it to a proper height for a channel to carry it off. The reader will find a description of several new and useful engines of this kind under the article, DRAINING MACHINES.

Improvement of drained BOGS. The most lasting and most perfect improvement of bogs, is effected by paring off their surface and burning it. *See the articles* MOOR and BURNBAKING. In order to this the bogs should be levelled; and whatever earth remains unemployed in filling up hollows, should be burnt together with that taken out of the ditches, unless the latter has been already carried off for fuel. The greater quantity of ashes there is, the greater will be the improvement of the soil itself, and the more will the earth brought upon it be benefited. The fire on the surface of the moss, exhales a very considerable part of the bituminous acid of this soil, and the fixed alkaline salt, always found in some proportion in the ashes, corrects or neutralizes it, so that no inconvenience arises from it afterwards, if the ground be kept dry, as it ought to be. The fire should not be fierce but rather smothered.

When the bog is pared, and the clods are collected to dry, the farmer must prepare earth to cover the surface. Marle, which is often found under bogs, presents the best covering that can be desired. If a clay lies under the bog, it must be prepared before it is spread in the manner directed under the article COMPOST, excepting only that the quantity of other substances mixed with it, such as dung, &c. need not be so great in this case, because the ashes, and the bog itself, will greatly assist in opening the body of the clay. If a loamy earth be near at hand, it will perhaps be less expensive to the farmer to bring such earth to cover the bog, than it will be to dig and prepare the clay. But of whatever kind the earth be, which is laid upon the bog, the quantity should always be sufficient to cover its whole surface four, five, or six inches deep, according to the stiffness of the soil so brought. Thus four inches of clay, when mixed with the ashes, and a due quantity of the earth of the bog itself, will give a depth of covering mould equal to what six inches of loam will do, when likewise mixed in proportion to its quality. If the bog be intended for arable land, the depth of the covering earth should be greater; because all kinds of grain, especially wheat, require at least a foot depth of good mould to extend their roots in, before they come to any cold or tenacious substance like peat or clay. The covering, therefore, of clay or marle should be in this case, six or seven inches thick, and that of loam eight or nine inches.

As soon as the surface is burnt, its ashes should be spread and mixed with the additional covering, which will then be fit for the farmer's purpose, whether for corn or grass. If the extent of the bog intended to be improved be considerable, it should be advisable, by means of a sluice, to fill the ditches contiguous to the spot which is to be covered, and to bring the earth in barges, or flat-bottomed boats, kept on purpose to transport the necessary manures, and the produce of the ground. By this means a saving will be made of the surface otherwise necessary for cart-ways. Besides, this soil, especially, when newly trained, does not well bear heavy carriages; a circumstance which renders it needless to observe, that broad wheels are always the most proper, when any must be used upon such land.

The bog being covered with a proportion of earth, the husbandman must next determine to what lasting purpose he can best apply it. The too great moisture of these soils, which always lie flat, renders them unfit for continued tillage; and their mould becomes so loose, by frequent ploughing, that it does not afford sufficient stability to the roots of corn. For this reason, barley, oats, and rye, do better here than wheat, which requires a firmer footing: but neither of them should ever be sowed thick; because the fruitfulness of the soil will always make up in the size of the plants, what some might think wanting in their number. The most beneficial method of employing this sort of land is, undoubtedly, by converting it into meadow; because, when thus prepared, and not injudiciously exhausted by crops of corn, it will yield great quantities of excellent grass. It is, however, usual to begin with sowing some kind of grain on this prepared surface, to indemnify the farmer by the plentiful crop which it generally yields; such, indeed, as sometimes defrays at once the whole expence of the improvement. Perhaps the most profitable method may be, to sow it in the autumn with rape, the leaves of which, shading the surface in hot weather, and rotting in the winter, contribute greatly to mellow the earth;

the ſtrong roots of this plant open the ſoil; its aſhes enrich it, when burnt, and its ſeed brings a great return when ſold for making oil. One or two ploughings will then prepare it for a crop of wheat. After this is taken off, and the ſtubble turned down or burnt, white clover and graſs ſeed from upland paſtures ſhould be ſowed, and the ground ſhould then be laid down for a laſting meadow; or, if turnips are ſowed, or cabbages planted, in the autumn, theſe, in the ſpring, may be ſucceeded by barley, with which the graſs ſeeds may be ſowed.

When, either through neceſſity, for want of other arable land, or out of choice, the farmer intends to continue ploughing his improved bog, the ſurface muſt be raiſed in ridges, and the farther management of it may be like that of moſt other ploughed grounds.

If a ſoil of this kind happens to be ſituated near a town, a greater profit will accrue from planting it with garden ſtuff, than from any ſort of grain. Beans, peaſe, cabbages, potatoes, turnips, carrots, &c. thrive exceeding well in ſuch earth as this, as the marquis of Turbilly experienced to his entire ſatisfaction.

"I received, ſays he, from Straſburg, in the year 1755, ſome ſeed of the large hard cabbage, which was immediately ſowed in my garden, from whence it was afterwards tranſplanted into a bog, which I had drained and cleared. This ſpot contains about an acre of ground, and forms a kind of iſland in my river. It had been pared and burnt; but never received any other manure than the aſhes produced by that burning; no ſort of dung having ever been laid upon it. The whole of it was planted with this kind of cabbage, excepting only a corner, where a few carrots, parſnips, and beet-roots, all of which grew to a prodigious ſize, and proved exceeding good, were ſet out of curioſity. Theſe cabbages throve wonderfully, ſeveral of them weighing forty pounds a piece, were well taſted, and very wholeſome, though ſome of the country people ſeemed poſitive that they and the other pot-herbs would be hurtful, unhealthy food, as, ſaid they, all plants are during the firſt year of their growth in new drained bogs.

"Theſe people pretended to have experienced this in other places; but not finding it ſo here, I aſcribed the effect they talked of to ſome pernicious quality in the ſoil; for I was very ſure, that the violent operation of the fire which mine had undergone, had not left any bad property in the earth. During the reſt of the ſummer, and the autumn, ſome of the neighbouring peaſants, whom I hired for the purpoſe, carried this great quantity of cabbages to the markets of three different towns, about ſix miles off: there they ſold them; and the accounts which they gave me of their produce amounted in all to eight hundred and fifty livres, that is thirty-ſeven pounds, three ſhillings, and nine pence. The wages of theſe men and the expence of carriage, amounted to about half this ſum; which being deducted, my acre of bog produced clear four hundred and twenty-five lives, that is, eighteen pounds eleven ſhillings, and ten-pence halfpenny, with which I was the better ſatisfied, as the cultivating of it had coſt me but little. The ſoil, being light, was eaſily turned up, though fat; and I had drained off the water without difficulty, by means of a ſlope which happened to be properly ſituated. I never had been offered above a crown a year for this marſhy land, which was quite a ſhaking bog, and often overflowed. When drained, its ſurface ſunk a foot lower than before. So great a produce, from ſo ſmall a ſpot of ground, of which no one knew the goodneſs, ſhews what vaſt riches are hid beneath the ſeveral bogs in this kingdom. They are not, however, all like this, which chanced to be a very fertile ſoil. I could wiſh to be maſter of ſeveral others like it. It has ſince been ſowed with hemp, peaſe, and ſeveral other plants, which have done very well, though none of its crops have produced ſo much money as this firſt; which ſhews the difficulty of ſetting a juſt value upon land. All the other bogs which I have drained and cleared in different ways, have anſwered, in general; but no one ever yielded, in proportion, any thing like this ſpot." *Memoire ſur les Defrichemens, pag.* 167.

BOG-*Spavin*, an encyſted tumour, or according to doctor Bracken, a collection of browniſh gelatinous matter, contained in a bag or cyſt, which he thinks to be the lubricating matter of the joint altered, the common membrane that incloſes it forming the cyſt: this caſe he has taken the pains to illuſtrate by an inſtance of a young colt of his own, where he obſerves, that when the ſpavin was preſſed hard on the inſide of the hough, there was a ſmall tumour on the outſide, which convinced him the tumour was within ſide the joint: he therefore cut into it, diſcharged a large quantity of this gelatinous matter, dreſſed the ſore with doſſils dipped in oil of turpentine, putting into it, once in three or four days, a powder compoſed of calcined vitriol, alum, and bole: by this method of dreſſing, the bag ſloughed off, and came away, and the cure was ſucceſsfully completed without any viſible ſcar.

This diſorder, according to the above account, will ſcarcely ſubmit to any other method, except firing, when the cyſt ſhould be penetrated to make it effectual; and in all obſtinate caſes that have reſiſted the above method, both the cure of this, and the ſwellings called wind-galls, ſhould be attempted in this manner. If, from the pain attending the operation or dreſſings, the joint ſhould ſwell and inflame, foment it twice a day, and apply a poultice over the dreſſings, till it is reduced. *Bartlet's Farriery, pag.* 279.

BOIL, a diſeaſe to which cattle, eſpecially ſheep, are very ſubject.

In order to cure theſe boils, it will be neceſſary to bring them to a head, by applying to them a plaſter compoſed of wheat flour, yolks of eggs, and tar: and when they feel ſoft under the finger, to open them with a lancet, and let out the matter. Then anoint the part with ointment of tobacco, and apply over it the following plaiſter. Take of turpentine, burnt ſalt, honey, and galbanum, of each one ounce; of roſin an ounce and a quarter. Melt the whole into a ſalve over the fire. *Ellis on Sheep, pag.* 101.

BOLE, the body or trunk of a tree.

Bole alſo ſignifies the ſtalk or ſtem of corn.

Bole, a meaſure of corn, containing four buſhels.

Bole *of Salt*, contains two buſhels.

BOLING *Trees*, pollard trees, or thoſe whoſe heads and branches are cut off, and only the boles or bodies left.

BONE, a hard, brittle, inſenſible part of an animal body, affording form and ſupport to the whole machine.

All marrow-bones, fiſh-bones, hoofs, horns, or ſhavings of horn, are very uſeful in manuring lands. Bones are moſt ſerviceable when raſped or broken into ſmall pieces; becauſe their ſalts, in which their principal vir-

tue conſiſts, are more eaſily extracted by the rains and dews, and communicated to the ſoil.

BONE-*Spavin*, a boney excreſcence, or hard ſwelling growing on the inſide of the hock of a horſe's leg.

A ſpavin that begins on the lower part of the hock, is not ſo dangerous as that which puts out higher, between the two round proceſſes of the leg-bone; and a ſpavin near the edge is not ſo bad as that which is more inward towards the middle, as it does not ſo much affect the bending of the hock. A ſpavin that comes by a kick or blow, is at firſt no ſpavin, but a bruiſe on the bone, or membrane that covers it; therefore not of that conſequence, as when it proceeds from a natural cauſe: and thoſe that put out on colts, and young horſes, are not ſo bad as thoſe which happen to horſes in their full ſtrength and maturity; but in very old horſes they are generally incurable.

The uſual method of treating this diſorder, is by bliſtering and firing, without any regard to the ſituation or cauſe, from whence it proceeds. Thus if a fullneſs on the fore-part of the hock comes after hard riding, or any other violence which threatens a ſpavin, ſuch coolers and repellers are proper as are recommended in ſtrains and bruiſes. Thoſe happening to colts and young horſes are generally ſuperficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by ſevere means.

There are various forms for making what is called the bliſtering ointment; but of the beſt of that kind, and what will infallibly anſwer the intention, has been already given under the article BLISTERING OINTMENT.

When a bliſter is thought neceſſary, the hair ſhould be cut as cloſe as poſſible, and then the ointment applied pretty thick over the part; this ſhould be done in the morning, and the horſe kept tied up all day without any litter till night; when he may be untied in order to lie down; and a plaſter of pitch, or any other ſticking ſubſtance, may be laid over it, and bound on with broad tape, or a bandage, to keep all cloſe.

After the bliſter has done running, and the ſcabs begin to dry and peel off, it may be applied a ſecond time in the ſame manner as before; the ſecond application generally taking greater effect than the firſt, and in colts and young horſes makes a perfect cure.

When the ſpavin has been of long ſtanding, it will require to be renewed perhaps five or ſix times; but after the ſecond application a greater diſtance of time muſt be allowed, otherwiſe it might leave a ſcar, or cauſe a baldneſs; to prevent which, once a fortnight, or three weeks, is often enough; and it may in this manner be repeated ſix or ſeven times, without the leaſt blemiſh, and will generally be attended with ſucceſs.

But the ſpavins that put out upon older, or full aged horſes, are apt to be more obſtinate, as being ſeated more inward; and when they run among the ſinoſities of the joint, they are for the moſt part incurable, as they then lie out of the reach of applications, and are arrived to a degree of impenetrable hardneſs.

The uſual method in theſe caſes is to fire directly, or to uſe the ſtrongeſt kind of cauſtic bliſters; and ſometimes to fire and lay the bliſters immediately over the part; but this way ſeldom ſucceeds farther than putting a ſtop to the growth of the ſpavin, and is apt to leave both a blemiſh and ſtiffneſs behind; beſides the great riſk run (by applications of theſe fiery and cauſtic medicines, to the nervous and tendinous parts about the joints) of exciting violent pain and anguiſh, and deſtroying the limb.

The beſt and ſafeſt way therefore is to make trial of the bliſtering ointment given under that article, and to continue it according to the directions above laid down, for ſome months, if found neceſſary; the horſe in the intervals working moderately: the hardneſs will thus be diſſolved by degrees, and wear away inſenſibly.

When the ſpavin lies deep, and runs ſo far in the hollow of the joint, that no application can reach it, neither firing nor medicines can avail, for the reaſons abovementioned: though bold ignorant pretenders have ſometimes ſucceeded in caſes of this ſort by the application of cauſtic ointments with ſublimate, which act very forcibly, enter deep, and make a large diſcharge; deſtroying by that means a great part of the ſubſtance, and diſſolve away the remainder. Though whoever is at all acquainted with the nature of ſuch medicines, muſt know how dangerous in general their operation is on theſe occaſions, and that a properly prepared cautery made like a fleam, under the direction of a ſkilful hand, may be applied with leſs danger of injuring either tendons or ligaments. After the ſubſtance of the ſwelling has been properly penetrated by the inſtrument, it muſt be kept running, by precipitate mixed with the medicine uſed in dreſſing the part, or with a mild bliſtering ointment.

Where the ſpavin lies not deep in the joint, and the bliſtering method will not ſucceed, the ſwelling may be ſafely fired with a thin iron forced pretty deep into the ſubſtance, and then the part ſhould be dreſſed as above directed. *Bartlet's Farriery, pag.* 257.

BOORCOLE. *See* BORECOLE.

BOOSE, a ſtall. Thus ox-booſe ſignifies an ox-ſtall, &c.

BOOT, profit, gain, advantage.

BORECOLE, *or* BOORCOLE, a ſpecies of cabbage, of which there are three ſorts, namely, the common borecole, the green borecole, and the Siberian borecole, which is the curled colewort, by ſome called Scotch kale. All theſe are for winter uſe, but the laſt is moſt eſteemed. The two former are ſown about the middle of April, and are fit for tranſplanting in about two months after. When this is done, the plants of either of theſe ſorts ſhould be ſet a foot aſunder in rows two feet diſtant from each other. They ſhould not be eaten before the froſt has rendered them tender; for till then they are tough and bitter. The Siberian borecole, which is extremely hardy, never injured by froſt, and always ſweeter in ſevere winters than in mild ones, need not be ſown till the middle of July, and when the plants are ſtrong enough for removing, that is when they have ſix or eight leaves, they ſhould alſo be ſet in rows; the diſtance between which ſhould be about two feet, and that between the plants, ten inches. Theſe will be fit for uſe ſoon after Chriſtmas, and continue good till April. The ſoil for borecole ſhould be a good, freſh, deep-looſened earth.

Borecole has been lately found by Mr. John Wynn Baker, to be an excellent food for cattle; and the Society for the Encouragement of Arts has accordingly offered two premiums for cultivating it, one of twenty, and the other of fifteen pounds.

Mr. Baker made the experiment under the direction of the Dublin Society, who deſired him to print his account of

of the experiment, an abſtract of which we ſhall give the reader.

This experiment was made on a piece of ground that had been cropped the preceding year with potatoes. After he had reduced the ſoil to a pretty good tilth, and manured it with a compoſt compoſed of earth, lime, and dung, he planted three rows of borecole plants, in ridges two feet aſunder. On the 17th of Auguſt they were horſe-hoed for the firſt time, by taking off, at one furrow of the plough, only one ſide of each ridge cloſe to the plants; in which manner they remained till the twenty-fifth, when he ran the plough in the ſame furrow, by which with the firſt furrow, he ploughed about twenty-one inches deep. This being finiſhed, the earth was immediately returned back to the plants, which afforded them freſh nouriſhment; and in order to give their roots time to penetrate this freſh earth, which, by the horſe-hoeing was become very fine mould, he let them remain in this ſtate till the 12th of September, when he horſe-hoed them again, by taking off the other ſide of every ridge; and on the twentieth deepened the furrow in the ſame manner as the former, and immediately returned the mould back to the plants; and on the eighteenth threw up a ſmall furrow to each ſide of every ridge, which finiſhed the culture, and reſtored the ridges to the form they were in when the borecole was planted.

"On the 18th of December, continues Mr. Baker, I cut two perches in length of one of the rows of borecole, which contained twenty-one plants; they weighed one hundred and eighteen pounds, which is very near five pounds ten ounces for each plant: but I am inclined to believe that theſe plants will ſucceed as well, if they are planted only eighteen inches aſunder in the rows. However, at the above proportion, there would be ſeventeen tons, and fourteen hundred upon an acre. But, if the produce would be the ſame, were the plants only eighteen inches aſunder, in that caſe, an acre would produce, by this culture, above twenty-three tons, and twelve hundred.

"This plant is well worthy the farmer's or grazier's attention, for, as faſt as it is cut, it will again, in about a month or ſix weeks, afford another crop: I have been cutting theſe plants for my family uſe, ever ſince the middle of Auguſt laſt; I believe ſome of them have been cut three times, and they are excellent for the table. For feeding cattle and ſheep they are highly valuable, as no froſt will injure them; and although the firſt crop amounts not to as many pounds upon any given quantity of ground as thoſe of cabbage or the turnip-cabbage, yet the ſucceeding crops will, I believe, make their produce nearly, or quite, of equal weight with any other of the cabbage kind. But I muſt not omit to obſerve, that, as theſe plants afford only open leaves, and many of them very ſmall, there will be a little more trouble in collecting and carrying them to the ſheep and cattle, than there will be with the other kinds.

"It may not be improper to obſerve likewiſe, that, upon the approach of ſpring, when they begin to throw out their ſpring ſhoots for ſeeds, if the large leaves have not been taken off for winter uſe, they will decay and fall off.

"I have not yet tried it; but I believe the beſt way of uſing this plant, would be to allot one whole field to the culture of it, proportioned in ſize to the ſtock intended to conſume the produce; and in September or October, to turn the ewes into the field for a few hours, morning and evening, and then to lodge them on any piece of graſs or fallow, which may want improvement, to which they will greatly contribute by emptying themſelves upon it; and thus continue to turn them into the borecole field, till they have eat all the luxuriant leaves; then let the plants reſt a month, and there will be another crop. By having two ſmall fields under this crop, a flock of ſtore ſheep might be maintained a whole winter at a very ſmall expence; for while the produce of one field would be conſuming, the other would be coming on.

"This method accrued to me from an accident which attended my borecole this year. My cows got into the field, and preſently devoured ſome of the leaves of the plants; theſe plants have engaged my attention ever ſince, and I have the pleaſure of ſeeing them again in a very luxuriant ſtate.

"If any perſons ſhould be able to put this ſcheme in practice, before I can accompliſh it, I recommend it to them not to let the ſheep paſture ſo long on the crop, as to injure the ſtalks for want of leaves; as too great an injury to the ſtalks may check the ſucceeding growth; which injury, I am inclined to believe, will not happen to the plants, at leaſt not in ſo great a degree, whilſt they have a ſufficient quantity of leaves.

"It will doubtleſs be obſerved, that I confine this ſcheme to ewes or ſtore ſheep: my reaſon for that is, that fat ſheep ſhould always have as much food before them, as they chooſe to eat; add to this that ſheep when they are fat, are more ſubject to be lame than ſtore ſheep, to which ploughed ground will greatly contribute."

BORD-*Lands*, the demeſnes which lords keep in their own hands, for the maintenance of their board or table.

BORD-*Service*, the tenure of bord-lands, by which the tenants were to provide proviſions for their lord's tables. There is ſtill ſome remains of this tenure remaining; but the tenants pay only a ſmall rent per acre, inſtead of finding the proviſions formerly required.

BORER, or *Screw-borer*, an inſtrument invented by the marquis of Turbilly, for ſearching or exploring the nature of any ſoil.

This borer is compoſed of two rods of iron, Plate I. Fig. 6 and 7. each ſix feet long, and an inch in diameter. The end A, of Fig. 6, ſcrews into the end B, of Fig. 7, after taking out the ſtopper C, the uſe of which is to hinder either dirt or duſt from getting into the ſcrew. The ſcrew is an inch and a half long, and three quarters of an inch in diameter. D, Fig. 6, is a ſteel point ſomewhat blunt to pierce the earth, or any ſubſtance it may meet with. It ſhould be about three inches long, and made with either three, four, or more ſides, as may be thought moſt convenient. It is ſcrewed into the rod A in the ſame manner, and with a ſcrew of the ſame ſize as A is ſcrewed into the rod B. It is a groove ſix inches long, a third of an inch wide, and three quarters of an inch deep, rounded in the bottom, and intended to bring up part of each different layer through which it paſſes. When ſprings are ſought for, a bit of ſponge is put into the groove. At the end F, of the rod, Fig. 7, is a ſcrew to fix into another rod of the ſame kind, if it be found neceſſary to lengthen the inſtrument; and this may be repeated by the addition of more rods, to any depth deſired. G H, Fig. 6, is the handle of this inſtrument, two feet and a half long.

long. This handle is faſtened to the rod by means of a claſp I, lined with ſteel, fixed at one end by a hinge, and at the other by the ſcrew L; ſo that it may be placed at any height. Fig. 8, is the handle ſeparated from the rod, and marked with the ſame letters as before. Fig. 9, marked with the ſame letters as before, is another handle, or rather lever, like the handle already deſcribed, except its having only one branch or lever marked G. This ſerves to ſtop the borer when we are bringing it up from a conſiderable depth, and alſo to ſcrew and unſcrew the ſeveral bars, or joints, as occaſion requires: and to put on, or take off the ſteel point at the bottom. The handle G A, Fig. 6, is that by which the rod is held, and worked into the earth, either by twiſting it round, eſpecially at firſt, or after it has penetrated to the ſame depth, by lifting it up, and letting it fall again, which it does with ſuch force as to pierce even the hardeſt rocks; eſpecially if it works at any conſiderable depth, and has of courſe been lengthened accordingly; for every foot of this rod weighs three pounds. Two men will eaſily ſound the depth of twelve feet in leſs than a quarter of an hour, if they do not meet with many ſtones. When the rod becomes too heavy to be properly managed by hand, it may be raiſed by a rope faſtened at one end to the handle, and at the other to a roller, or kind of windlaſs, erected at a proper height, perpendicularly over the hole, and turned with either one or both handles. This will coſt but a trifle, and will eaſily raiſe the other rod, which, when let go, will fall with ſuch weight, as to ſtrike each time very deep into the earth. The marquis tells us, that he has ſeen it worked in this manner to the depth of more than an hundred feet.

The toughеſt iron is the beſt for making this inſtrument, which ſhould be well hammered, till its ſurface be quite ſmooth and even: for the leaſt roughneſs and inequality would occaſion a friction, which would greatly retard its working. For the ſame reaſon, and alſo to increaſe the force of its fall, it is neceſſary that it ſhould be perfectly ſtrait: nor ſhould it ever be ſtruck with a mallet, hammer, &c. to force it down; becauſe a blow might bend it, and it would eaſily break afterwards. The female ſcrew muſt be turned like that in the breech of a gun barrel, in a ſeparate piece of iron, croſs-ways to the grain, and this piece muſt be afterwards well ſoldered on to one of the ends of the rod. The reaſon for this is, that if the female ſcrew were bored only at the end of the rod, it would, by being hammered out in the ſame direction with the grain, be ſtringy and porous, and conſequently ſo weak as to give way, or burſt, in the working of the rod; whereas when made of a ſeparate piece, taken croſs-ways of the grain, the threads of the ſcrew will run with the grain of the iron, and be thence conſiderably ſtrengthened. A bit, like that of an augre, proportioned to the thickneſs of the rod, may at any time be ſubſtituted inſtead of the ſteel point, to draw up a ſample of the ſubſtance from the very bottom of the ſounding.

If the only thing wanted be to know the nature of the under ſoil, and layers of earth, ſo far as they may effect the vegetation of plants, it will be very ſufficient to bore eight or ten feet deep. A greater depth is only requiſite when water, marl, ore, &c. be ſought for.

The common augre indeed will do very well for ſhallow boring, as we have already obſerved under thar article. *See the article* AUGRE.

By either of theſe inſtruments, there is a certainty of diſcovering, without much charge, or any hazard, not only what earths are under the upper ſoil, but alſo whether any other ſubſtance of value lies concealed there, ſuch as marle, chalk, fuller's-earth, foſſile ſhells, coals, quarries of ſlate or ſtone, ores, &c. many of which are hid, and entirely unthought of in places, where their value, was it known, is ten times more than that of the eſtate which covers them.

BORING, an operation ſometimes practiſed for the cure of horſes, whoſe ſhoulders are wrenched.

The operation is performed in the following manner: they cut a hole in the ſkin in the middle of the ſhoulder, and with the ſhank of a tobacco-pipe, blow it as a butcher does a ſhoulder of veal; then they run a cold flat iron, like a horſeman's ſword-blade, eight or ten inches up between the ſhoulder blade and the ribs, which they call boring; after that, they burn him round the ſhoulder with a hot iron. *Burd. Gent. Far.*

This is a very abſurd and cruel treatment, and can be of no manner of ſervice. *Bartlet's Farriery.*

BOSTAL, a way up a hill.

BOTTS, a name given to a ſpecies of worms infeſting horſes and other cattle.

The botts which grow in the ſtomach of horſes, and which are ſometimes the cauſe of convulſions, appear to be very large maggots, compoſed of circular rings, with little ſharp prickly feet along the ſides of their bellies (like the feet of hog-lice) which, by their ſharpneſs, equal to that of the fineſt needle, ſeem to be of uſe to faſten them to the part where they breed, and from whence they draw their nouriſhment, and alſo to prevent their being looſened from ſuch adheſion, before they come to maturity. The eggs from whence theſe botts are produced, are diſpoſed in cluſters round the lower orifice of the ſtomach, and are layed under the inner coat, or thin membrane of the ſtomach; ſo that when the animals come to life, they burſt through this inner coat, their breech and tail ſtrait outwards, and their trunks ſo fixed into the muſcular or fleſhy coat of the ſtomach, that it ſometimes requires a good pull to diſengage them: from the blood of this laſt coat they draw their nouriſhment, which they ſuck like ſo many leeches, every one ulcerating and purſing up the part where it fixes, like a honey-comb; and they often make ſuch quick havock as to deſtroy the horſe.

The botts which many horſes are troubled with in the beginning of the ſummer, are always ſeen ſticking to the ſtrait gut, and are often thruſt out with the dung, together with a yellowiſh coloured matter reſembling melted ſulphur; they are no ways dangerous there, but are apt to make a horſe reſtleſs and uneaſy, and rub his breech againſt the poſts. The ſeaſon of their coming is in the months of May and June, after which they are ſeldom to be ſeen, and rarely continue in any one horſe above a fortnight or three weeks. And the creature may be eaſily cured when they are only in the ſtrait gut, by giving him a ſpoonful of ſavin cut very ſmall, once or twice a day in his oats, or bran, moiſtened: three or four cloves of garlick may alſo be added to advantage. The following purge ſhould likewiſe be given:

Take fine ſuccotrine aloes ten drams; freſh jallap one dram: birthwort and myrrh powdered, of each two drams; oil of ſavin and amber, of each one

one dram; ſyrup of buckthorn enough to form the whole into a ball.

But the botts, which take their lodgment in the ſtomach, are, as has been already obſerved, extremely dangerous, by cauſing convulſions, and are ſeldom diſcovered by any previous ſigns before they come to life, when they throw the horſe into violent agonies. The only cure for theſe is mercurial medicines; the following will anſwer the inention:

Take quickſilver two drams; Venice turpentine half an ounce; rub the quickſilver till no gliſtening appears; then take an ounce of aloes, a dram of grated ginger, thirty drops of oil of ſavin, and ſyrup of buckthorn enough to make the whole into a ball.

One of theſe balls may be given every ſix days, with the uſual precautions with regard to mercurial phyſic: and the following powders immediately:

Take powdered tin and Æthiops mineral, of each an ounce; and give it every night in a maſh, or in his corn.

Theſe medicines, or any of the various preparations of antimony and mercury, ſhould be continued ſeveral weeks together, in order to free the animal entirely from theſe vermin. *Bartlet's Farriery, pag.* 150.

BOUDS, a name in ſome countries for the inſects generally called weevils, breeding in malt.

BOW, a name in ſome countries for a yoke.

BOWS *of a ſaddle*, are two pieces of wood laid archwiſe to receive the upper part of the horſe's back, to give the ſaddle its due form, and keep it ſteady.

BOX, the name of a well known tree, of which botaniſts enumerate ſeven ſpecies viz. 1. The box-tree. 2. The narrow leaved box-tree. 3. The ſtriped box. 4. The gold-edged box-tree. 5. The dwarf box. 6. The dwarf ſtriped box. 7. The ſilver edged box.

The firſt and ſecond ſorts grow in great plenty upon Box-hill near Darking in Surry, where were formerly large trees of theſe kinds: but of late they have been pretty much deſtroyed; yet there are great numbers of theſe trees remaining, which are of a conſiderable bigneſs. The wood of this tree is very uſeful for turners, engravers, and mathematical inſtrument makers; the wood being ſo hard, cloſe, and ponderous, as to ſink in water; which renders it very valuable for divers utenſils.

All the varieties of the trees, or large box, are proper to intermix in clumps of ever-greens, &c. where they add to the variety of ſuch plantations: theſe may be propagated by planting the cuttings in autumn in a ſhady border, obſerving to keep them watered until they have taken root; when they may be tranſplanted into nurſeries, till they are fit for the purpoſes intended. The beſt ſeaſon for removing theſe trees is in October; though, indeed, if care be uſed to take them up with a good ball of earth, they may be tranſplanted almoſt at any time, except in the ſummer: theſe trees are a very great ornament to cold and barren ſoils, where few other things will grow; they may alſo be propagated by laying down the branches, or from ſeeds: the laſt being the beſt method to have them grow to be large, the ſeeds muſt be ſown, ſoon after they are ripe, in a ſhady border, which muſt be duly watered in dry weather. *Miller's Gard. Dict.*

Box *of a wheel*, the aperture wherein the axis turns.

Box *of a plough*, the croſs-piece in the head of a plough which ſupports the two crow-ſtaves. *See* PLOUGH.

BRACE, a general name for a couple, or pair of any thing, as bucks, hounds, partridges, &c.

BRACE alſo ſignifies a piece of timber framed into the beams, &c. with bevel joints, to keep the building from ſwagging either way.

BRACKEN, the ſame with brakes, or fern. *See the article* FERN.

BRACKET, or BRAKET, a ſort of compound drink, made with honey, ſpices, &c.

BRAKE, the ſame with fern. *See the article* FERN. It is likewiſe applied to the place where fern grows.

BRAKE, is alſo a name given to an inſtrument often uſed by farriers, &c. generally called barnacles. *See* BARNACLES.

BRAKE *of a pump*, ſignifies the handle wherewith it is wrought.

BRAKE, is likewiſe the name of a wooden-toothed inſtrument, uſed to bruiſe and break the bun of hemp, and ſeparate it from the rind. *See the article* HEMP.

BRAN, the ſkin or huſks of corn, eſpecially wheat, ground and ſeparated from the flour by means of a ſearch or boulter.

Bran is a uſeful ingredient in a horſe's diet, if diſcretely uſed, and when ſcalded is a kind of panada for ſick horſes. But nothing is worſe than a continual uſe of bran raw or ſcalded, as it is apt to weaken a horſe's bowels, and thereby expoſe them to many diſorders. *Gibſon on the Diſeaſes of Horſes, vol.* I. *pag.* 172.

Mr. Mills aſſures us, that a little wheat bran boiled in our ordinary beer, will make it mantle in the cup. *Huſbandry, vol.* I. *pag.* 407.

BRANCH, an arm of a tree, or a part which ſprouting out from the trunk, helps to form the head or crown.

BRANK, the ſame with buckwheat. *See the article* BUCKWHEAT.

BRANT, a ſteep, riſing with a conſiderable inclination.

BRAWN, the fleſh of a boar, boned, rolled up, or collared, boiled, and laſtly pickled.

Brawn is made only of the flitches, without the legs: the oldeſt boars are choſen for this uſe, it being a rule, that the older the boar the more horny the brawn.

The method of making it is as follows: the bones being taken out of the flitches, the fleſh is ſprinkled with ſalt, and laid in a tray, that the blood may drain off; after which it is ſalted a little, and rolled up as hard as poſſible. The length of the collar of brawn ſhould be as much as one ſide of the bone will bear; ſo that when rolled up it may be nine or ten inches in diameter.

The collar being thus rolled up, it is boiled in a copper or large kettle, till it is ſo tender that you may run a ſtraw through it: when it is ſet by till thoroughly cold, and then put into the following pickle. To every gallon of water add two handfuls of ſalt, and as much wheat-bran; boil them together, drain the liquor as clear as poſſible from the bran, and when the liquor is quite cold, put the brawn into it.

BREAD, a well-known food chiefly divided into white, wheaten, and houſhold; differing only in degrees of purity. In the firſt, all the bran is ſeparated; in the ſecond

only

only the coarſer; in the third, none at all; ſo that fine bread is made only of flour; wheaten bread of flour, with a mixture of fine bran; and houſhold, of the whole ſubſtance of the grain, without taking out either the coarſe bran, or fine flour.

We alſo meet with ſymnel bread, manchet or roll bread, and French bread: which are only ſo many denominations of the fineſt or whiteſt bread, made of the pureſt flour; except that in roll bread there is an addition of milk, and, in French bread, of eggs and butter alſo. To which may be added, ginger-bread, made of white bread, with almonds, liquorice, aniſeed, roſe-water, and ſugar; and maſlin-bread, made of wheat and rye, or ſometimes of wheat and barley.

The proceſs of making houſhold bread amongſt us, is thus; to a peck of meal they add a handful of ſalt, a pint of yeaſt, and three quarts of water, cold in ſummer, hot in winter, and temperate between the two; the whole, being kneaded in a bowl or trough by the fire in winter, from it in ſummer, and a little yeaſt added, will riſe in about an hour; they then mould it into loaves, and put it into the oven to bake. *Hought. Collect.*

For leavened bread, part of the flour intended for it, being made into dough with warm water and a little ſalt, is laid in the reſt of the flour an hour or more, in which time it riſes to three times the bulk; then they mix and knead the whole with more water, till it be brought into a ſtiff dough; which, being formed into loaves, is baked in the oven: though the more uſual way is to take a piece of dough kneaded, and leave it in the tub till next time, when they break it ſmall, and mix it with the meal, adding ſome yeaſt. *Hought. Collect.*

For French bread, they take half a buſhel of fine flour, ten eggs, and a pound and a half of freſh butter, into which they put as much yeaſt, with manchet; and, tempering the whole maſs with new milk, pretty hot, let it lie half an hour to riſe; which done, they make it into loaves or rolls, and waſh it over with an egg beaten with milk; care is taken the oven be not too hot. *Ruſt. Dict.*

BREAK, land ploughed the firſt time after it has lain fallow in ſheep walks.

BREAST-PLOUGH, a ſmall plow contrived ſo that a man may ſhove it before him. It conſiſts of a cutting iron about eight or nine inches long, and having one of its ſides turned up to cut the turf. This iron is fixed to a pole bending upward about five or ſix feet long, and forked at the upper-end, having a crutch, or croſs handle, mortiſed into the forks. Againſt this crutch the ploughman places his breaſt, and ſhoves along the plough in order to turn up the turf, its only uſe being for cutting up the ſurface of the ground in the operation called burn-baking. See the article BURN-BAKING.

BRECK, *or* BRACK, a breach or gap made in a hedge.

BREW-HOUSE, a houſe erected for the purpoſes of brewing.

The conveniency of water is one of the firſt things to be attended to in erecting a brew-houſe, becauſe the frequent carriage of that neceſſary fluid greatly enhances the coſt of the beer. The water ſhould be ſoft, and if ſupplied from an adjacent river, it ſhould be conveyed by a paſſage under-ground, in order to its being pumped up from thence into the copper, or into troughs properly placed for carrying it where it may be wanted. If there be a reſervoir for rain-water, it ſhould be made as near the brew-houſe as poſſible.

The brew-houſe ſhould be ſo ſituated as to face the north, for ſhade and coolneſs. It ſhould be as near as poſſible to the cellar, that the labour and expence attending the carriage of the liquor may be ſaved, and the danger of expoſing it to either too hot, or too cool an air prevented. The floor ſhould be paved with ſtone or hard bricks, and raiſed in the middle, to give an eaſy diſcharge to the water, ſo as to keep the brew-houſe always clean.

The copper ſhould be proportioned to the quantity brewed, and ſhould be raiſed ſo high that the water may run from it to the maſh-tub, and the wort to the coolers. For this purpoſe there ſhould be either a cock in the ſide at the bottom of the copper, or a braſs pump ſhould be fixed to its ſide, by means of which the water or wort may be conveyed through a trough to their proper receptacles.

The maſh tub ſhould be round, not too deep, and perfectly ſmooth on the inſide. It ſhould have a falſe bottom, which may ſerve as a ſtrainer, when by turning a cock placed below, the wort may be drawn off into the receiver: or the wort may be let out by means of an upright plug ſurrounded with a baſket-ſtrainer.

The receiver ſhould be lined with milled lead, which is eaſily kept perfectly clean, and is not apt to contract any bad taſte or ſcent, as wood is known to do, notwithſtanding the greateſt care. The beſt method of conveying the wort from the receiver to the copper is by means of a hand pump.

There ſhould be two coolers, or backs, as the brewers call them. Theſe ſhould alſo be lined with milled lead, or made of the heart of oak rendered perfectly ſmooth; and placed as near as convenient to the copper.

The working veſſel or tun ſhould be placed at ſome ſmall diſtance from the cooler. It ſhould be round, but not lined with lead; becauſe this would cool the liquor too much in cold weather during the fermentation.

The cellar ſhould, as already obſerved, be near, if poſſible, and ſunk much lower than the working-tun, that the beer may be conveyed into the caſks by a cock and hoſe, or ſome other eaſy method.

There muſt be in the brew-houſe an oar to ſtir the malt in the maſh-tub, with bowls, pails, and other utenſils, neceſſary in different operations. Theſe, as well as every other implement employed in brewing, ſhould be boiled in the copper, or well ſcalded every time before they are uſed.

Too great care cannot be taken to keep every veſſel perfectly clean and ſweet; for if they are the leaſt tainted, the liquor will contract a diſagreeable ſcent. When any taint is ſuſpected, the veſſels ſhould be well waſhed with a ſtrong leye of clean wood-aſhes. This leye ſhould be put into them ſcalding hot, and every joint, crevice, and ſmalleſt hollow muſt be well ſcrubbed. If there are no aſhes to be had, lime may be ſlaked in water in the veſſels; and if this be done in caſks, they may be bunged up as ſoon as the ebullition is over, and not opened till three days after. The more effectually to prevent the lodging of any kind of filth, the ſides of every veſſel ſhould be as ſmooth as poſſible; and after every brewing they ſhould be waſhed with boiling water, and laid up dry.

BREWING, the operation of preparing beer, or ale, from malt and hops.

The uſual proceſs of brewing is as follows: the ingredients being ready, the water muſt be made to boil very ſpeedily, and while boiling with the greateſt violence, the fire muſt be immediately damped, or put out; when the height of the ſteam is over, the water is put into the maſh-

ing-

ing-tub, to wet the malt; then ſo much being poured out, as to make it of a conſiſtence ſtiff enough to be rowed up, let it ſtand thus a quarter of an hour, after which another quantity of water is added, and rowed up as before; at laſt the full quantity of the water is poured upon it, and that in proportion as the liquor is intended to be ſtrong or weak: this part of the operation is called maſhing. Afterwards the whole may be left to ſtand two or three hours, more or leſs, according to the ſtrength of the wort, or the difference of the weather; then let it run into the receiver, and maſh again for a ſecond wort, in the ſame manner as for the firſt, only the water muſt be cooler, and muſt not ſtand above half the time.

The two worts being mixed together, the quantity of hops that is deſigned may be added thereto, and the liquor put into the copper, which being cloſely covered up, let boil gently for the ſpace of an hour or two; then let the liquor into the receiver, and the hops ſtrained from it into the coolers.

When cool, the barm is applied; which done, it is left to work, or ferment, till it be fit to tun up.

For ſmall-beer there muſt be a third maſhing; the water muſt be near cold, and to ſtand not above three quarters of an hour; to be hopped and boiled at diſcretion.

Such is the proceſs, as commonly delivered, for brewing; but it is in many particulars ſo vague and uncertain, that proper explanations will be requiſite.

The malt is ordered to be put into the maſh-tub, when the height of the ſteam is over; but how is this to be known exactly? Some direct you to ſtay till you can ſee your face in the water, which is full as equivocal. Perhaps the method propoſed by Dr. Shaw might anſwer the purpoſe. He directs us to put a certain meaſured quantity of cold water to the malt firſt, and ſtir that very well with it, ſo as to form a kind of thin uniform paſte; after which the remaining quantity of the water may be added in a ſtate of boiling, without the leaſt danger. By this means, adds that able chemiſt, the proper or preciſe degree of heat, neceſſary to extract the virtue of the malt with all advantages, may be very expeditiouſly hit, or aſſigned, to a great exactneſs; as the heat of boiling water is a ſtandard, which may at once be let down to any deſired point of warmth, by a proper addition of cold water; due allowance being made for the ſeaſon of the year, and the temperature of the air.

To employ only one copper in brewing is generally allowed to be bad management; becauſe the buſineſs muſt, in that caſe, ſtand ſtill in ſome part or the other, however well the proceſs may be contrived. For this reaſon, the beſt and more uſual method is to brew with two coppers.

The great copper in which the water for the two firſt extracts receive their temperature, is built very near the maſh-tub, ſo that the water may be readily conveyed to the ground malt. At the bottom of the copper is fixed a cock, which being turned, lets the water run through a pipe to the real bottom of the maſh-tub. This is by far the beſt way, becauſe it is the moſt expeditious, and leaſt liable to accidents.

When the water has been brought to a proper degree of heat in the maſh-tub, the malt is run very leiſurely into it, whilſt another perſon ſtirs it all the time, ſo as to mix the whole of it uniformly with the water, and prevent any of its parts from gathering into clods. In this operation rakes ſhould be firſt employed; becauſe by their horizontal motion, leſs violent than that of maſhing, the fineſt parts of the malt are well wetted, without its flour being ſcattered or loſt in the air: but as a ſtill more perfect penetration and mixture are neceſſary, oars are afterwards uſed, by which a thorough inhibition of the water is effected. When the maſh has been ſufficiently ſtirred, it is covered with a ſprinkling of malt, and the tub itſelf ſhould alſo be covered with ſacks or other cloths to keep it warm.

After maſhing, the malt and water are left untouched for an hour and a half, or two hours; and during this interval, the large copper of water is brought to a proper heat for a ſecond maſhing. The ſecond extract is commonly maſhed three quarters of an hour, and is afterwards let ſtand the ſame ſpace of time; and the third requires half an hour, both for maſhing and ſtanding. As the firſt drawn wort is immediately put into the large copper, the water for the third maſhing is boiled in the ſmaller.

Small quantities of malt brewed in large veſſels loſe their heat ſooneſt by lying thin and greatly expoſed to the action of the air; and, on the contrary, a leſs allowance for the loſs of heat is required for large quantities brewed in proportionable veſſels. This is the only difference between brewing carried on in large brew-houſes, and thoſe which are made in private families. Care ſhould be taken that the quantity of malt be not ſo large as to exceed the bounds of one man's labour; nor ſo ſmall as to prevent the heat being uniformly maintained. It is alſo of great importance never to let the malt remain with leſs water than will cover it.

It is the general cuſtom in private families to brew their ſmall-beer after their ale: but they may be aſſured that if they have any regard to their ſmall-beer, it is their intereſt to brew it alone; for the beer thus made is incomparably better, becauſe it then contains all the flavour of the malt, is undoubtedly more wholeſome, and will keep much longer.

A correſpondent of the editors of the *Muſeum Ruſticum*, vol vi. p. 287, has given the following uſeful directions for making a kind of ſmall-beer, which for cheapneſs, agreeableneſs, and perhaps wholeſomeneſs, is greatly preferable to that made from malt. It has alſo this further advantage, that it may be made ready for drinking in three or four days time.

The method is this: take of water fifteen gallons; and boil one half of it in any copper or pot that may be at hand. Put the part of the water thus boiled, while in its full heat, to the cold part contained in a barrel or caſk: and then add one gallon of melaſſes, commonly called treacle, ſtirring them well together. If the veſſel be new, add a little yeaſt; but if it has been uſed before for the ſame purpoſe, the yeaſt will be unneceſſary. Keep the bung-hole open for a day or two, till the fermentation appears to be abated, and then cloſe it up. The beer will in a day or two afterwards be fit to drink.

But to return to the management of the wort. The beer-wort muſt be boiled, in order to free it from particles which would render the liquor muddy and ill coloured, without adding to its ſtrength; to extract the virtue of the hops; and to render the drink fitter for keeping.

Worts, like every other ſweet vegetable juice, when once brought to ferment, are ſo inclined to continue their fermentation, that it is difficult to retard their progreſs therein, to keep their preſervative qualities, and ſo hinder them from turning acid. Among the many methods put in practice to retard this forwardneſs of the worts, none promiſed ſo much ſucceſs as blending with them the juice of ſuch vegetables as are not of themſelves

eaſily fermented. Hops are ſelected for this purpoſe; and experience, which has proved their wholeſomeneſs, has alſo demonſtrated their efficacy: for their reſinous parts retard the aptneſs of malt liquors to ferment. By this means they keep malt-liquors ſound a longer time, and by repeated and ſlow frettings, give an opportunity to the particles of the liquor to be more ſeparated and comminuted, than they would otherwiſe be. Fermented liquors require hereby a greater pungency, ſo that, even if they did not receive an additional ſtrength from this ingredient, hops would be the means of improving their taſte.

The aromatic parts of hops are volatile, and a ſmall heat diſengages them from the plant. To preſerve theſe parts in the proceſs of brewing, the hops ſhould be put into the copper as ſoon as poſſible, and be thoroughly heated while the heat of the wort is at the leaſt, and the fire under the copper has no effect there. Whoever will take the trouble of ſeeing this performed, will be convinced that the flavour of the hops is retained; inſtead of being diſſipated in the air, as it always is, when the wort is firſt ſuffered to boil.

In order to extract more gradually a fragrant tincture from the hops, they ſhould be rubbed thoroughly between the hands, and then put into a bag or fine net, ſo looſe that the wort may be eaſily admitted among them, and in this ſtate they ſhould be placed in the receiver or under-back, ſo that the wort may run upon them. After this gradual ſoaking, during which they will communicate much of their virtue to the wort, leſs boiling will ſerve, and the beer will have their full flavour.

A correſpondent of the editors of the *Muſeum Ruſticum, vol.* III. *pag.* 64, has made ſome judicious remarks on the common practice of boiling the hops in the wort. He obſerves that the rich, fat wort, ſheaths up the pores of the hop, and, as it were, embalms the leaves, ſo that the beer or ale-wort can extract a very ſmall part only of the neceſſary quality of the hop: but when it is put into the ſmall beer, a fluid of a thinner nature, the pores are unſheathed; ſo that the latter becomes too bitter, while the former has hardly any taſte of the hop. To remove theſe inconveniencies, he propoſes to ſoak the hops previouſly in a pail or two of hot water, by which means the hop will impart its good qualities impartially, and both the ſtrong and ſmall beer obtain a grateful bitter. And with regard to the quantity of water uſed in ſoaking the hops, allowance may be made for it in the firſt quantity.

When the firſt wort is ſufficiently boiled, it is conveyed into the coolers; and if the hops are not contained in a net, it muſt be run though a ſieve or ſtrainer, to keep them back. If the coolers have not been perfectly cleaned from the ſediment of former worts, which is very apt to inſinuate itſelf into old or decayed wood, the wort intended to be cooled in them, will, before it is removed, contract from that ſediment a degree of fermentation. This accident generally happens in a little more than twelve hours after the putting in of the wort; and therefore may be eaſily prevented by not letting the wort continue ſo long in the coolers.

When the wort is of a proper degree of coolneſs, the yeaſt is generally put into a large bowl, and a little of the wort juſt warm is added to it. The yeaſt ſwims at firſt on the ſurface, but ſoon blends itſelf with the wort, and begins the fermentation. As ſoon as this happens, the whole is mixed with the wort in the working tun.

If the fermentation ſhould not riſe properly, a little of the fineſt wheat flour ſifted over the wort, ſo as to cover the whole ſurface of the liquor, will, by forming a kind of artificial head, confine the air, and ſoon produce the effect deſired. If a greater degree of warmth ſhould be wanted, a ſtone jug filled with boiling water, and put into the wort, will communicate a gentle heat to the whole, and as the liquor warms, the fermentation will come on in a gradual and proper manner.

In the courſe of the fermentation, it may ſometimes be neceſſary, in order to quicken it, to beat in the yeaſt, or rather to ſtir it with a wiſk, which ſhould be perfectly clean, ſcalded in boiling water, and then wiped dry. It will alſo by this means retain ſome degree of warmth, which will likewiſe help to promote the fermentation. Theſe meaſures, with an additional warmth given to the air, and warm coverings laid over the working tun, ſeldom fail to anſwer the end deſired.

If the fermentation proceed too violently, owing to the warmth of the weather, or too great quantity of yeaſt, the beſt way of checking it is, to cool the air, by giving it a more free admiſſion, and to mix a little cold wort with the fermenting liquor. The practice of adding ſome unctuous ſubſtance is bad, and therefore ſhould be rejected.

Care ſhould be taken to have the caſks in good order againſt the time that the fermentation is completed in the tub; that is, they ſhould be tight and clean, and perfectly free from filth or ſmell; for if they have either of theſe defects, the whole labour will be loſt, becauſe the excellency and fine flavour of the liquor will be deſtroyed.

The perfection of malt liquors depends not only on the proportion of the oils to the ſalts, and on the proportion of hops uſed in brewing, but alſo on the fermentation's being carried on ſlowly and cooly. For this reaſon cool weather is beſt for brewing of beer intended for long keeping. If therefore the liquor be not drawn off before the fermentation has proceeded too far, ſome of the coarſer oils will return into the liquor, and give it a diſagreeable and greaſy taſte. On the contrary, if the fermentation has not been continued its due time, the impurities which would either have ſunk down in the lees, or have been thrown up with the head, will remain in the liquor, and prevent its becoming clear and well taſted.

When the fermentation is at its height, all the dirt or foul yeaſt, which riſes on the ſurface, muſt be carefully ſkimmed off.

When the fermentation begins to ſubſide after the liquor has been drawn off into the caſk, the caſk ſhould be filled up with a reſerve of the ſame liquor taken from another veſſel, but by no means with that which runs over.

When the fermentation has ceaſed, the caſk being filled up, ſhould be bunged cloſe down, leaving the vent-hole open, or but ſlightly covered, till all motion in the liquor is ſubſided; and after this is over, the vent-hole ſhould be ſtopped quite cloſe. The cuſtom of uſing bungs made of cork is wrong. A wooden bung ſhould be fitted to the bung-hole as exactly as poſſible, and covered with a clean cloth.

BRIDLE, a contrivance made of ſtraps or thongs of leather, and pieces of iron, in order to keep a horſe in ſubjection and obedience.

The ſeveral parts of a bridle are, the bit or ſnaffle, the head-ſtall, or leather from the top of the head to the rings of the bit; the fillet, over the forehead and under the fore-top; the throat-band, which buckles from the head-band under the throat; the noſe-bands, going through the loops at the back of the head-ſtall, and buckled under the cheeks; the reins or long thongs of leather that come from the rings of the bit, and being caſt over the horſe's head, the rider holds in his hand.

BRIDLE-*Hand*, is the horſeman's left-hand, the right being called the ſpear or ſword-hand.

BRIM, *or* BRIMME, a word applied to a ſow when ſhe goes to the boar, which is called going to brim.

BRINE, pickle, or water replete with ſaline particles.

BRINING *of Hay-Reeks*, a practice common in America, and conſiſts in mixing ſalt with the hay as they ſtack it.

A correſpondent of the editors of the *Muſeum Ruſticum* recommends this practice greatly, declaring that hay which has to all appearance been ſpoiled by the rain, will ſpend as well as that made and ricked in the fineſt weather.

"Juſt before I left America, ſays he, I had a crop of hay, which was in a manner ſpoiled by the rain, being almoſt rotted in the field; yet did this hay ſpend as well as if it had been got in ever ſo favourably.

"When my ſervants were making up the ſtack, I had it managed in the following manner; as ſoon as the bed of hay was laid about ſix inches thick, I had the whole ſprinkled over with ſalt; then another bed of hay was laid, which was again ſprinkled in the ſame manner; and this method was followed till all the hay was ſtacked.

"When the ſeaſon came for cutting this hay, and giving it to my cattle, I found that ſo far from refuſing it, they eat it with ſurprizing appetite; always preferring it to the ſweeteſt hay, that had not been in this manner ſprinkled with ſalt." *Muſeum Ruſt. vol.* II. *p.* 210.

BRITE, a word applied to hops when they are over ripe or ſhatter, in which caſe they are ſaid to brite.

BROAD-WHEELED *Waggon*. *See the article* WAGGON.

BROKEN-WIND, a very fatal diſeaſe to which horſes are too often ſubject.

This diſorder hitherto ſeems to have been little underſtood; but Mr. Gibſon is inclined to think, that the ſource of it is frequently owing to injudicious, or haſty feeding young horſes for ſale; by which means the growth of the lungs, and all the contents within the cheſt, are ſo increaſed, and, in a few years, ſo preternaturally enlarged, that the cavity of the cheſt is not capacious enough for them to expand themſelves, and perform their functions.

A narrow contracted cheſt with large lungs may ſometimes naturally be the cauſe of this diſorder; and it has been obſerved, that horſes riſing eight years old, are as liable to this diſtemper, at a certain period of life, as men fall into aſthmas, conſumptions, and other chronic diſeaſes.

The reaſon why this diſorder becomes more apparent at this age may be, that a horſe comes to his full ſtrength and maturity at this time: at ſix commonly finiſhes his growth in height; after which he lets down his belly, and ſpreads, and all his parts are grown to their full extent; ſo that the preſſure on the lungs and midriff is now more increaſed.

But how little weight ſoever theſe reaſons may have, repeated diſſections have given ocular proofs of a preternatural largeneſs, not only of the lungs of broken-winded horſes, but of their heart and its bag: and alſo of the membrane which divides the cheſt; as well as of the remarkable thinneſs of the diaphragm or midriff.

This diſproportion has been obſerved to be ſo great, that the heart and lungs have been almoſt of twice their natural ſize; perfectly ſound, and without any ulceration whatever, or any defect in the wind-pipe or its glands.

Hence it appears, that this enormous ſize of the lungs, and the ſpace they occupy, by hindering the free action of the midriff, is the chief cauſe of this diſorder; and as the ſubſtance of the lungs was found more fleſhy than uſual, they muſt of courſe have loſt much of their ſpring and tone.

This fleſhineſs and ſize of the lungs may, in a great meaſure, be the cauſe, why the inſpirations in broken-winded horſes are diſproportionately ſlow; for we may obſerve that they draw in their breath ſlowly, their flanks filling up, and riſing with difficulty: but that their flanks fall ſuddenly, and their breath burſts forth with violence, both from mouth and noſtrils; inſomuch, that a man in the dark, by holding his hands on the horſe's mouth and noſe, may eaſily diſcover if he is broken-winded.

Whoever conſiders a broken-wind in this light, muſt own that it may be reckoned among the incurable diſtempers of horſes; and that all the boaſted pretenſions of cure, are vain and frivolous, ſince the utmoſt ſkill can amount to no more than now and then palliating the ſymptoms, and mitigating their violence.

We ſhall therefore lay down ſuch methods as may probably prevent this diſorder, when purſued in time; but if they ſhould not ſucceed, we ſhall offer ſome remedies and rules to mitigate its force, and to make a horſe as uſeful as poſſible under this malady.

It is uſual before a broken-wind appears, for a horſe to have a dry obſtinate cough, without any viſible ſickneſs or loſs of appetite; but, on the contrary, a diſpoſition to foul feeding, eating the litter, and drinking much water.

In order then to prevent, as much as poſſible, this diſorder, bleed him, and give him two drams of calomel, mixed up with an ounce of diapente, for two nights ſucceſſively, keeping him cloathed and well littered; and feeding him with ſcalded bran and warm water.

The following balls are then to be taken for ſome time, which have been found extremely efficacious in removing obſtinate coughs:

> Take gum ammoniacum, galbanum, and aſſa fœtida, of each two ounces; ſquills, four ounces; cinnabar of antimony, ſix ounces; ſaffron, half an ounce: make the whole into a paſte with honey; and give a ball about the ſize of a pullet's egg every morning.

Broken-winded horſes ſhould eat ſparingly of hay, which, as well as their corn, may be wetted with cham-

ber-lye, or ſair water; as this will make them leſs craving after water.

The volatile ſalts in the urine may render it preferable to water, and may be the reaſon why garlick is found ſo very efficacious in theſe caſes; two or three cloves given at a time in a feed, or three ounces of garlic bruiſed, and boiled in a quart of milk and water, and given every other morning for a fortnight, having been found very ſerviceable; for by warming and ſtimulating the ſolids, and diſſolving the tenacious juices, which choak up the veſſels of the lungs, theſe complaints are greatly relieved.

Careful feeding and moderate exerciſe has greatly relieved broken-winded horſes; and though for the firſt ſummer they have not been able to endure much labour, yet many have been found leſs oppreſſed the ſecond, and ſome ſcarce perceptibly affected the third; and even able to bear great fatigue: and could a horſe be kept conſtantly in the field, and taken up only when uſed, he might, by this management, do good ſervice for many years.

But whoever expects to cure his horſe by ſending him out to graſs, will find himſelf diſappointed, eſpecially if he remains abroad after the ſpring graſs; for on his return to the ſtable and dry meat, he will be more oppreſſed and ſhort breathed than before, for want of the open air, and the moiſt food he has been accuſtomed to.

Horſes ſent to graſs in order to be cured of an obſtinate cough, have often returned completely broken-winded, where the paſture has been rich and ſucculent, ſo that they have had their bellies conſtantly full. As the ill conſequence therefore is obvious, where you have not the convenience of turning out your horſe for a conſtancy, you may ſoil him for a month or two with young green barley, tares, or any other young herbage.

To purſive, thick winded horſes, Barbadoes and common tar have often been given with ſucceſs, to the quantity of two ſpoonfuls mixed with the yolk of an egg, diſſolved in warm ale, and given faſting two or three times a week, eſpecially on thoſe days you hunt or travel.

But in order to make all theſe ſorts of horſes of any real ſervice, the grand point is to have a particular regard to their diet, obſerving a juſt œconomy both in that and their exercife; giving them but a moderate quantity of hay, corn, or water, at a time, and moiſtening the former to prevent their requiring too much of the latter, and never exerciſing them but with moderation, as has been before obſerved.

The following ball may be given once a fortnight or three weeks; and as it operates very gently, and requires no confinement, except the days it is given (when warm meat and water will be neceſſary) it may be continued for two or three months.

> Take ſuccotrine aloes, ſix drams; myrrh, galbanum, and ammoniacum, of each two drams; bay berries, half an ounce; oil of amber, a ſpoonful: make the whole into a ball with a ſufficient quantity of ſyrup of buckthorn. *Bartlet's Farriery*, *p.* 68.

BROODING, that act of a hen, or other bird, ſitting on a number of eggs, to keep them warm, till they hatch, or produce young ones.

BROOM, the name of a plant, of which two ſpecies are natives of this country, called the common and the ſmall broom.

The common broom is the *geniſta trifolia* of Mr. Ray. It riſes about three feet in height, with ſhrubby ſtalks, garniſhed with ſpear-like leaves, and terminated by looſe ſpikes of yellow flowers, ſucceeded by ſhort pods, which turn black when ripe, and contain four or five kidney-ſhaped ſeeds. It flowers in June or July, and the ſeeds ripen in autumn. The flowers of this plant are uſed by the dyers to give a yellow colour; whence it is called dyers broom, green-wood, wood-waxen, or dyers weed.

The ſmall Engliſh broom, called alſo petty-whin, is the *geniſta ſpartium minus Anglicum*, of Tourneſort. It riſes like the former, with a ſhrubby ſtalk, but only to the height of about two feet, ſending out many ſlender branches, which are armed with long ſingle ſpikes, and garniſhed with very ſmall ſpear-ſhaped leaves, placed alternately on every ſide of the branches. The flowers branch out without ſpines, ſhort, and have five or ſix yellow flowers growing in a cluſter at the end. They come out in April and May, and are ſucceeded by ſhort turgid pods, containing four or five ſmall kidney-ſhaped ſeeds, which ripen in July. This ſort grows naturally upon open heaths, in many parts of England.

The twigs of broom are excellent for thatching barns, &c. being very tough, and of long duration. Ropes alſo, and thoſe not bad ones, are made of the ſtringy fibres of this plant, of which the ancients uſed alſo to make a kind of flax.

According to Mr. Bradley's calculation, an acre of broom is worth upwards of ſix pounds annually, for the feeding of bees only, beſides the wythes and ſtumps, which will pay for the rent of the land. Certain it is, that no flowers are more pleaſing, or more profitable to bees, than thoſe of broom.

But conſidered as a weed, is one of the moſt pernicious plants that grows upon the land; for its roots penerate deep, and, at the ſame time it ſheds no leaves, ſo that it is continually ſucking the moiſture from the earth. The beſt method of deſtroying it, is by burning the land, then ploughing it deep, and manuring it very well with dung and aſhes; or by ſpreading on the land chalk or marle, or manuring it with urine. If the ground be deſigned for paſture land, it is beſt to cut the broom cloſe to the ground in May, when the ſap is ſtrong in it. By this artifice the roots are deſtroyed; whereas in the common way of pulling up the young plants, ſome ſtrings of the roots will be left, and the leaſt of theſe will grow. Foddering of cattle upon broomy land is one very good way of deſtroying the broom, their urine killing the roots, and their treading the land makes it leſs proper for the roots to extend themſelves; for broom is ſeldom ſeen to grow near old paths. *Bradley's Huſbandry*, *vol.* I. *pag.* 181. *Mortimer's Huſbandry*, *vol.* I. *pag.* 308. *Mills's Huſbandry*, *vol.* III. *pag.* 361.

BROWN, a duſky kind of colour, inclining ſomewhat towards redneſs.

A brown horſe is not reckoned altogether ſo beautiful as the bay or cheſnut. There are alſo degrees of this colour, ſome being light, and others very dark. They have almoſt always black manes and tails, and often their joints are black, though not ſo ſhining as the bays, but ruſty. Almoſt all brown horſes grow gradually lighter towards their bellies and flanks, and many are

light

ſight about their muzzles. The moſt beautiful are thoſe which happen to be finely dappled, for the plain brown are eſteemed more ordinary. Many of them are coarſe, but ſtrong and ſerviceable, fit for draught, for burden, or for war. *Gibſon on horſes, vol.* I. *pag.* 46.

BROWN-STOUT, a name given in ſome parts to ſtrong brown beer, brewed from brown high-dried malt.

BROWSE, branches fit for the food of goats, &c.

BRUISE, a hurt cauſed by the force of ſomething blunt and heavy.

Horſes and other cattle are very ſubject to bruiſes from various accidents; but as the blood is no ways affected in theſe caſes, one general method of cure is only neceſſary; and that is by coolers and repellers, ſuch as white wine vinegar, old verjuice, or compoſitions made with allum, vitriol, and the like, which ſhould be applied frequently to the ſwelling, till the heat and inflammation is abated.

BUCK-BEAN, or *Marſh-trefoil, trifolium paluſtre*, a plant with large oval leaves, pointed at each end like thoſe of a garden bean, ſet three together on long pedicles, which embrace the ſtalk to ſome height, and there parting, leave it naked near the top, where iſſues a ſhort ſpike of pretty large, reddiſh, monopetalous flowers, each of which is cut into five ſegments, hairy on the inſide, and followed by an oval ſeed-veſſel. It is perennial, grows wild in marſhy places, and flowers in May.

Sheep, when ſound and in health, always avoid eating buck-bean; but when the ſymptons of the rot begin to attack them, they ſearch for it by inſtinct, and devour it greedily. Where ſuch ſheep are paſtured, no buck-bean is to be found, for in a week or two they devour it all. Might it not be prudent, therefore, in huſbandmen, who graze large flocks, to cultivate an acre of this plant in ſome moraſly ground, which otherwiſe would not yield them two ſhillings the acre? Some might be cut up green, for unſound ſheep, and given them with lucern, as occaſion requires; and ſome might be made into hay, and mixed with their fodder. I cannot remember that this advice has been given by any huſbandry writer. *Eſſays in Huſbandry, Eſſay* II. *pag.* 137.

BUCK-WHEAT, the name of a plant generally conſidered as a ſpecies of corn, though not ſuch in fact; nor does it grow like any of the eſculent grains. Its leaf, from being roundiſh at firſt, takes nearly the ſhape of that of ivy, but longer pointed, and much ſofter. Its ſtalk is round, hollow, and weak, ſometimes reddiſh, but moſt commonly green, and growing to the height of about two feet and a half. Lateral branches, which ſhoot out almoſt at every joint, are terminated by purpliſh flowers, which are ſucceeded by ſmall triangular ſeeds, black on the outſide, and white within.

Buck-wheat will thrive in any ſoil, not excepting even barren ſands, as they are commonly termed; but grows largeſt in dry ground which have been well ploughed. When raiſed for its grain, a buſhel of ſeed is ſufficient for an acre of land, which will frequently yield fifty or ſixty buſhels: but when it is intended for green fodder, which is the uſe moſt commonly made of it here, ſome people ſow three or four buſhels on an acre, in order to have a thick crop. The uſual time of ſowing it is about the beginning of May; but if it be ſowed ſomewhat earlier, and a warm ſeaſon enſues, it will bear, cutting twice in the ſummer. It comes up ſoon, and ripens generally, according to M. du Hamel, in one hundred days after ſowing, ſo that buck-wheat ſown in June is reaped in September.

When mowed, it muſt be left in the field ſeveral days, that its ſtalk may dry before it is houſed. There is little danger of the ſeeds falling out, nor is it much injured by wet. Theſe ſeeds are exellent food for pigeons, poultry, hogs, rabbits, &c. and are found to make horſes thrive when given among their oats: but for theſe they ſhould be firſt cracked in a mill; being apt, otherwiſe, to paſs through them whole. The flower of buck-wheat is very white, and makes a good ſort of pancake, when mixed with a litle wheat-flour. The poor in ſome countries make even bread of this mixture; but it is black, bitter, windy, and not nouriſhing. Its ſtraw, or haulm, is alſo given dry to catttle: but the beſt way is to feed it whilſt green, particularly juſt before it bloſſoms. Milch-cows fed with it will yield an extraordinary quantity of milk, remarkably good for making butter and cheeſe: and another advantage attending this paſture is, that it will continue green in the drieſt time of ſummer, when other graſſes are burnt up. It is an exellent dreſſing for land, where ploughed in without being mowed.

The ingenious author of the Eſſays in Huſbandry tells us, that in certain lands of Brabant, called Rempen, the huſbandmen raiſes buck-wheat in ſmall fields near home, and places round them, under the hedges, a great number of bee-hives, from whence he draws conſiderable profit; for no plant affords theſe inſects a better ſupply of materials for making honey. *Eſſay* I. *pag.* 110. *Mortimer's Huſbanary, vol.* I. *pag.* 136. *Du Hamel's Elements of Agriculture, vol.* I. *pag.* 91, *Maiſons Ruſtiques, tom.* I. *pag.* 624.

BUD, that part of the ſeed which firſt begins to ſprout, or rather the leaves which firſt appear.

BUD, alſo ſignifies the ſprout from whence the branch ariſes. Theſe buds in ſome meaſure reſemble ſeeds, as under a number of ſcaly coverings the rudiments of the young branch are ſeen: but neither the lobes nor the young root are met with; becauſe this tender ſtem is connected with a tree, which ſupplies it with the neceſſary food.

BUD is likewiſe uſed in ſome counties in England for a weaned calf of the firſt year; becauſe the horns are then in the bud.

BUGLE, *Middle compound, Sicklewort*, or *Herb Carpenter*, the name of a low weed, with two kinds of ſtalks; round creeping ones, which ſtrike root at the joint; and upright ſquare ones, hairy on two of the oppoſite ſides, alternately, from joint to joint, bearing looſe ſpikes of blue labiated flowers, of which the upper lip is wanting: the leaves are ſomewhat oval, ſoft, ſlightly cut about the edges, and ſet in pairs at the joints. It is a perennial weed, infeſting moiſt meadows and paſture-grounds, and flowers in May.

BUGLOSS, or *Viper's Bugloſs*, the name of a plant whoſe ſtalks are rough, round, ſolid, erect, undivided, and marked with black ſpots: the leaves are very rough, long, narrowing to a point, and placed without any certain order. The flowers are large and ſpacious, of a beautiful blue colour, and grow in long bending ſpikes. They conſiſt of one petal divided into five roundiſh ſegments, of different ſizes, and reſemble a horn in their figure.

figure, expanding by degrees, from a narrow beginning. The flower cup conſiſts of five narrow ſegments, and contains four rough ſeeds.

Bees are very fond of the viper's bugloſs, and there is reaſon to think that this plant, aſſiſted by the culture of a ſkilful gardener, may receive, perhaps, as many improvements as the auricula did. Its branches will riſe to the height of three feet, and no vegetable would better adorn flower-pots in large chimnies; for if the water be changed, it continues blowing near a fortnight after cutting. Its ultra-marine, blue-colour, is the fineſt that can be ſeen, and the ſtalks are garniſhed with flowers from top to bottom; dyers might, perhaps, extract an uſeful tincture from the roots. This plant grows wild in hard braſhy ſoils. *Eſſays in Huſbandry. Eſſay* I. *pag* 110.

BUILDING. *See the article* FARM-HOUSES.

BULL, the male of the ox kind. *See the article* Ox.

The bull, kept for propagating the ſpecies, ſhould have a quick countenance, his forehead broad and curled, his eyes black and large, his horns large, ſhort, and black, his neck fleſhy, his belly long and large, his hair ſmooth like velvet, his breaſt big, his back ſtrait and flat, his buttocks ſquare, his thighs round, his legs ſtrait, and his joints ſhort; this ſort of bull is the beſt for breed, and makes the beſt ox for draught. *Mortimer's Huſbandry, vol.* I. *pag.* 226.

The bull chiefly ſerves for propagation; and though he may be ſubject to the yoke, yet there is no being certain of his working quietly, and the uſe he may make of his prodigious ſtrength, is conſtantly to be guarded againſt. This creature is naturally untractable, ſtubborn, and fierce; and in the bulling ſeaſon, abſolutely uncontroulable, and often furious; but, by caſtration, the ſource of theſe turbulent impulſes is deſtroyed, without the leaſt diminution of his ſtrength. He alſo grows larger, more heavy and unwieldly, and becomes more adapted to the labour for which he is deſigned. This operation alſo renders him more tractable, patient, docile, and leſs troubleſome to others. A herd of bulls could not be either tamed or managed by human ſkill. *Buffon's Hiſtoire Naturelle, tom.* IV.

BULLEN, hemp ſtalks ſtripped from the bark.

BULLIMONG, or *Bullimony*, a mixture of oats, peaſe, and vetches.

BULLS-FOOT, the ſame with colts-foot. *See* COLTS-FOOT.

BULLWEED, *Great Knapweed*, or *Matfellon*, the name of a perennial weed common among corn; it riſes to about two feet high; the ſtalks are round, ſtreaked, and hoary: the bottom leaves are oblong and undivided, but thoſe which grow on the ſtalk are cut and divided. The flowers reſemble thoſe of the blue-bottle in ſhape, but are of a red colour. The ſeed is ſmall, oblong, reddiſh, and hairy in the upper part.

BUNS, the ſtalks of hemp after the bark is taken off.

BURN-BAKING, or *Burn-beating*, often called *Denſhiring*, or *Devonſhering*, from its being long practiſed in that country, a method of cutting up the turf, and after drying and burning it, the aſhes are ſpread over the ſurface by way of manure.

This method of improving land is very ancient, Virgil mentions it, and it has been practiſed time out of mind in Cornwal and Devonſhire. The marquis of Tourbilly has founded his famous treatiſe *Sur les Defrichemens*, publiſhed in 1761; principally on the art of burn-baking. We ſhall here give the ſubſtance of what the marquis has delivered on that intereſting ſubject.

When it is intended to break up any piece of waſte-ground, the nature of it ſhould be firſt conſidered, and may, in a great meaſure, be known from its natural produce, which is generally heath, ruſhes, fern, broom, furze, brambles, &c. intermixed with graſs: for, from the height, thickneſs, and vigour of this wild growth, a proper judgment may be formed with regard to the degree of the goodneſs of the ſoil, and what may reaſonably be expected from it.

When ſuch ground is to be broken up, it will be right to begin in the winter in order to get rid of the three principal obſtacles, namely, water, ſtones, and ſuch large roots as the paring mattock, or beating axe, as it is called in the weſt of England, may not be ſtrong enough to cut. Afterwards, about the middle of March, the paring of this ground ſhould be begun, by a number of labourers proportioned to the extent of the land intended to be pared.

Every one of theſe labourers muſt be provided with a paring-mattock, or beating-axe, the form of which is repreſented on Plate II. Fig. 1. Towards the edge, where it is ſharpened like an addice, it ſhould be made of well tempered ſteel, and about nine inches wide. From thence the iron part, which ſhould be ſix inches in length, leſſens in breadth towards the handle, as in Fig. 2. where it is reduced to three inches. All the upper part muſt be made of the beſt iron, and ſhould be formed ſomewhat hollow, with a little bending inward. It ſhould be ſtrongeſt in the middle, and of a thickneſs proportioned to its ſize, as well as to the work, for which it is intended. The hole to receive the handle ſhould be two inches in diameter, and the handle ſhould be of wood, about three feet long, or a few inches more or leſs, according to the height of the man who uſes it. This inſtrument, excluſive of the handle, ſhould weigh from ten to twelve pounds, according to the ſtrength of the labourer: a leſs weight would not be ſufficient for the purpoſe.

The ſtouteſt and moſt intelligent labourer muſt be then ſingled out to lead the reſt; for they cannot work in a row as when they dig. This leader ſtanding in a proper poſture to manage his beating-axe, muſt give two ſtrokes with it, cutting into the ſoil, to the right, two more ſtrokes to the left; and afterwards a fourth ſtrait before him; by which means he will immediately raiſe a turf about a foot and a half long, a foot broad, and four inches thick of earth. This turf reſting upon the axe as it was cut, is then, with one motion, to be placed on the labourer's right-hand, in its natural poſition, with the mould ſide downwards. (See Plate II. Fig. 3. where *a*, *a*, *a*, are three turfs as cut from the ſoil.) All the wild growth upon this land, will, if not very large, come off with the turfs thus cut; and the more there is of it, the better it will be. The turf muſt abſolutely be cut with a depth of at leaſt four inches of ſoil: for if the ground be pared to a leſs thickneſs, the work will be badly done; becauſe the beating-axe will not have gone under the netted roots of all the rubbiſh growing on the ſurface, which it is indiſpenſibly neceſſary to deſtroy: otherwiſe theſe roots will make freſh

freſh ſhoots, injure the corn, and in time choak it entirely, as has happened to me in the beginning of my undertakings.

The workmen, eſpecially if they undertake the work by the acre, would be glad to take this turf off as thin as poſſible; becauſe that would ſave them a great deal of time and labour. But I have experienced to my coſt the imprudence of making ſuch bargains. They muſt therefore be well watched; for otherwiſe, beſides the inconvenience of not effectually deſtroying the wild growth, ſuch thin turf would not yield a ſufficient quantity of aſhes for manuring the land. The buſineſs will indeed go on ſlower, but practice will ſoon render the workmen more expert.

Their leader having cut a turf, and placed it on his right-hand ſide, muſt then advance a ſmall ſtep, and take off another of the ſame ſize and thickneſs, which he muſt alſo place on the ſame ſide, in a line with the former, on the further end of which the neareſt end of this ſhould reſt, ſo as to incline a little. He is then to proceed ſtrait on, laying all the turfs in the ſame manner. As ſoon as he has taken up the two firſt turfs, the ſecond labourer, ſtanding on his left hand ſide, is to take up his line of turfs in the ſame manner, and place them on his right, in the void ſpace cleared by the leader. As theſe advance, each of the other labourers, ſucceſſively one after the other, muſt put himſelf on the left of the preceding, at the ſame diſtance, and do the ſame work, following each other like reapers. Thus, if the firſt began at B (Plate II. Fig. 10.) he lays his turfs along the line which terminates the plate; and when he has cut two turfs, the ſecond begins at C, and lays his turfs in the ſpace BA, cleared by the firſt. The third follows the ſecond in the ſame manner, clearing the ſpace FE, and laying his turfs in the ſpace CD, cleared by the ſecond. The fourth clears the ſpace GH, and the fifth JK, and ſo on. The ſame muſt alſo be underſtood of Fig, 8, and 9, which therefore require no further explanation.

When the labourers come to the end of the ground, which will likewiſe be in progreſſive order, the leader muſt return to the ſide where he firſt began, and reſume his work cloſe to the ſpace already pared, the others are to follow in their regular turns, and repeat the ſame operations as before; for this work muſt always be performed in the ſame direction, and not backwards and forwards. Such ſhould be the method till the whole ground is pared.

If, as it ſometimes happens, there be reaſon to apprehend that the ſods will not dry faſt enough when only laid a little ſlanting, with the end of one juſt reſting upon the extremity of another; they may in this caſe be piled, as faſt as they are cut, in little heaps of three, four, or five together, according to their thickneſs, and the quantity of combuſtible or vegetable matter contained in them. The air paſſing between theſe ſods, which are always laid with the heath or turfy ſide uppermoſt, penetrates and ſoon dries them, eſpecially if the weather be ſultry: but at the ſame time it would be wrong to wait till they are quite dry, becauſe they would then burn too much, and too faſt; in which caſe their aſhes are neither ſo good, nor in ſo great quantity, as thoſe of turf more ſlowly burnt. A juſt medium, which practice will eaſily teach, is to be obſerved in this reſpect.

Sometimes theſe turfs are ſet upon their ends, two and two meeting at the top, and being further aſunder at the bottom, like the roof of a houſe, with their heathy ſides outwards, as repreſented at *b*, *b*, *b*, (Plate II. Fig. 4.) but this method, which lengthens the work, and therefore renders it more expenſive, is fitteſt for the turfs of bogs or marſhes, when cut too wet.

With reſpect to the roots, which I ſaid muſt be got rid of before any land can be properly broken up, I meant only ſuch large roots as the beating-axe cannot cut through, though ſharpened with a whet-ſtone from time to time, when its edge is either turned or blunted. For with regard to the roots of ſmaller ſize, ſuch as thoſe of the dwarf furze, the common heath and young fern, ſmall holly, young plants of thorns and junipers, brambles, broom, and other wild productions, which have not attained too great ſtrength, will, without much difficulty, be cut and pared off with the turf.

But the ſtrong roots of ſhrubs, buſhes, &c. which the beating-axe cannot ſever, muſt remain in the ground, though that will not hinder our taking off the turf between them to a proper thickneſs. The ſods thus cut will indeed be often very irregular in length and breadth; but they are the better for burning, as they contain a greater proportion of vegetable matter.

It has been already obſerved, that theſe turfs ſhould be laid in little heaps as they are cut; theſe ſhould be placed in the intermediate ſpaces, where the ground has been placed between the roots yet remaining in the earth. Theſe roots ſhould be grubbed up with a ſpade, pickaxe, &c. without diſordering the little piles of ſods. It will be ſufficient if this work be finiſhed before the time of ſowing. *See the article* GRUBBING.

Some grub up theſe roots before they burn the turf, and others after, as beſt ſuits their convenience: but in the latter caſe they ſhould certainly be taken up in thoſe places where the furnaces are to be made, becauſe it is of great importance not to ſtir the heaps of aſhes produced by them, till the very inſtant of ſowing. The holes alſo made by pulling up large roots, ſhrubs, &c. ſhould be filled up ſo as to render the ſurface even. In countries where wood is ſcarce, theſe roots, ſtumps, &c. are carried away, and dried for fuel, eſpecially for the kitchen; by which means they frequently repay at leaſt the expence of grubbing them up. But in places where wood is of ſo little value as to render theſe not worth the carrying off, the beſt way is to burn them with the turf, the aſhes of which they will both increaſe and improve.

The thicker any land is covered with theſe wild productions, the better it will prove. If it coſts more than another parcel of ground to break up, and bring it into order, it will, in return, make ample amends, by producing greater crops.

When the ſeaſon is not too wet, the turfs will generally dry ſufficiently in about three weeks, even without being turned; but in rainy years they require a longer time, and muſt be turned again and again, to prevent their ſtriking out new roots and ſhoots, which would hinder them from burning, as I have ſeen happen. Hence it appears, that this method of clearing and breaking up ground requires a longer time, and is attended with more labour and difficulty in rainy than in dry ſeaſons. But as the turfs may be turned by women and children, the additional expence will not be very conſiderable.

About

About Midſummer, or a few days before, when the turfs are ſufficiently dry, a number of women and children ſhould be employed, in fine clear weather, to gather them all up, ſome with iron forks, others with their hands, and pile them up from ſpace to ſpace, in round heaps about ten feet high, and of the ſame width at bottom, almoſt in the ſhape of charcoal furnaces. The heathy ſide of the turf muſt be placed downwards, and the earthy ſide upwards. A ſmall hollow ſhould be left in the inſide, in order to form a kind of chimney, the opening of which ſhould face the wind. *a b* (Plate II. Fig. 5.) repreſents a furnace of this kind partly built, where *f* is the door, or opening into the chimney of the furnace. Fig. 6. is a furnace completed, where *e* is the top of the chimney, and *d* the door. Fig. 7. repreſents a great number of theſe furnaces on fire.

It has been already obſerved, that this work muſt not be ſet about in rainy weather; becauſe if the heaps of turf ſhould unfortunately be ſo much wet as to imbibe the water, they would not burn, but muſt be pulled down and ſpread anew, to dry as before. They might alſo, in this caſe, require very frequent turnings, as has happened to me; which would retard the operation, and increaſe the expence: beſides which, it might not even be poſſible, by frequent turnings, to dry them ſufficiently, before autumn, if the rains were frequent, which muſt occaſion a very conſiderable loſs.

However, this laſt accident, though poſſible, is very rare. It never befel me; and by enquiring of thoſe to whom it has happened, I found that it was, in a great meaſure, owing to their own negligence. The beſt method to avoid theſe inconveniencies is, to embrace the advantage of the firſt fine weather, and if it appears at all uncertain, to ſet more hands to work, without aiming at an ill-timed ſaving: for it is upon the due piling up and burning of the turfs, after being properly cut and dried, that the whole ſucceſs of this important branch of huſbandry chiefly depends. It cannot therefore be done too ſpeedily. When rain is apprehended, every other buſineſs ſhould be left for this, and all hands, men, women, and children, ſhould be inſtantly employed, to diſpatch it as ſoon as poſſible. Nothing requires greater diligence. The heaps ſhould be ſet on fire the moment they are finiſhed, or at leaſt, though the weather ſhould ſeem ſettled, before the huſbandman retires in the evening. Children may do this, by putting a little lighted ſtraw or heath, with an iron fork, into the chimnies of the furnaces. The dry heath, graſs, and roots, will catch inſtantly, and in a few moments the fire will become ſo violent, as ſcarcely to be approached. It may then be left, after taking proper precautions to prevent its extending further than it ought; eſpecially if it be near any wood, hedge, or heath, where it might otherwiſe do great miſchief.

The misfortunes occaſioned by fire have been ſo numerous and dreadful, that too much care cannot be taken to guard againſt them. If the ſituation of the land which is to be burned be ſuch as gives the leaſt room to fear any danger of this kind, the furnaces ſhould only be lighted in calm weather; leaſt the wind ſhould ſpread the flames to neighbouring grounds, where it might be impoſſible to ſtop them till they had done irreparable damage.

If it be ſurrounded on all ſides with woods, heath, or other vegetables eaſily ſet on fire, a row of furnaces ſhould, in this caſe, be made around the land to be burned, at the diſtance of twenty-five, or thirty feet from the neighbouring grounds, and at leaſt ten feet from the other furnaces, which are afterwards to be built farther within this incloſure. Care ſhould then be taken to obſerve from which ſide the wind comes, and fire ſhould be ſet to thoſe furnaces that are ſituated fartheſt from the wind, or neareſt to that ſide on which the wind blows. A number of men ſhould watch theſe furnaces while they burn, and ſhovel up earth upon them, if they are ſo full of heath or combuſtible matter as to occaſion too violent a flame.

The throwing on of this earth will deaden the flames, and concentrate the fire; by which means the furnaces will be conſumed by ſlow degrees, without hurting either the outward borders of the pared land, or its inner parts, where this fire might do miſchief two ways; firſt by ſpreading to, and burning the yet unpiled turfs, the aſhes of which would ſoon loſe their virtue, if ſcattered upon the ſoil in this looſe manner; and ſecondly, by catching the other furnaces, in caſe they ſhould be already made; by which means the fire would ſoon become ſo great, that it would be no longer poſſible to ſtop its progreſs, or prevent its extending to the neighbouring grounds.

When the firſt row of furnaces is thus conſumed, the next row may be burnt in the ſame manner, and ſo on till the whole is finiſhed.

The morning is doubtleſs the moſt proper time for lighting all theſe furnaces, becauſe the people employed in buſineſs have then the whole day before them, to watch the fire and prevent accidents, which it might be very difficult to remedy in the night, particularly during the firſt violence of the flames. A number of proper perſons proportioned to the extent of the ground, ſhould remain upon the ſpot all night, as well to attend the burning of the turf, as to hinder wicked wretches from ſetting fire to other places, of which there have been too many inſtances.

By not neglecting any of theſe precautions, though all of them are not neceſſary where the fire cannot ſpread to adjacent grounds, every inconvenience may certainly be avoided.

If it ſhould be found neceſſary to light the furnaces in the evening, though as I have juſt obſerved, the morning is a much fitter time for it, they muſt be ſuffered to continue burning till the next day, when the violence of the fire will be abated. A few men, or even women and children, ſhould be then ſent in among the heaps, with iron forks, to give them a little ſtirring, and lay upon them the turf which may have fallen down. Theſe furnaces will ſtill continue burning for ſome days, during which the turfs will be ſlowly conſumed or calcined. If any of them ſhould be ſituated on wet ſpots, where they will not burn, theſe women and children muſt mend them, and add freſh fuel, ſuch as dry heath, ſtubble, or even a little dry wood, with ſome of the burning turfs from the adjacent furnaces. As ſoon as the fire is extinguiſhed in all the heaps, which will be then reduced to heaps of aſhes, finer or coarſer in proportion to the goodneſs of the ſoil, the women and children muſt ſhovel them up into little round heaps, leſt they ſhould loſe their fertilizing quality, if left in the manner they fell in their burning: for all our treaſures conſiſts in the ſalts contained in theſe little heaps, and the

the volatile parts of thoſe ſalts, which are much the beſt, would ſoon fly off, if expoſed to the air. The dews at night, and the firſt rain which falls upon thoſe heaps of aſhes, form on their ſurface a cruſt, which hinders their being blown away by the wind, renders them impenetrable to the action of the air, and keeps in all their virtue: the ſooner therefore rain falls after this operation, the better. Nor would it be any injury if it ſhould rain as ſoon as the furnaces are thoroughly lighted, unleſs it ſhould be very violent indeed, and of long continuance, which rarely happens at this ſeaſon.

When the aſhes are thus laid up in little heaps, nothing more remains to be done to this ground till the time of ſowing; care indeed muſt be taken, that neither men nor cattle approach them ſo as to break their cruſt. The land will from hence be freed from all ſeeds of weeds, and other wild productions, as well as from all worms, inſects, reptiles, and venomous creatures; the action of the fire of the furnaces being ſo ſtrong, that it heats not only the earth, beneath them, to the depth of ſeveral inches, but likewiſe all the intermediate ſoil.

A fortnight after the uſual ſeed-time of the country, for wheat and rye, will be early enough to ſow this burnt ground. When that is to be done, a number of women and children ſhould be ſent into the field, on a ſtill, calm day, with wooden ſhovels, to ſpread the aſhes equally over all the ground, excepting the ſpots where the furnaces were; for theſe are ſo thoroughly burnt, that they want no farther manure, and are always obſerved to produce the fineſt corn. Some of theſe women and children ſhould alſo carry iron forks, to break and ſpread ſuch turfs as may not have been thoroughly conſumed; for theſe having been baked or calcined by the action of the fire, will be very beneficial to the land.

Immediately after the aſhes are ſpread, the corn, whether wheat or rye, ſhould be ſown over thoſe aſhes by a ſkilful ſower, in not more than about half the quantity generally uſed for a ſimilar extent of other ground. The ploughman ſhould follow the ſower, with his team, either of horſes or oxen, yoked to a ſtrong plough, having two fins to the ſhare. *See the article* PLOUGH. He ſhould not, however, cut too deep this firſt year, but make only ſhallow furrows, going and returning, to cover the ſeed. Women and children, with hoes and iron forks, ſhould then be employed to break carefully all the clods, together with every remaining bit of turf; and finally to cloſe the tops of the ridges, which the plough cannot do with the neceſſary exactneſs in this ploughing. If ſeveral ploughs work at the ſame time, as is generally the caſe with many, the number of women and children muſt be increaſed in proportion, and there muſt be a ſower before each plough.

It is very difficult to ſow theſe lands with half the quantity of ſeed generally uſed in other places. The moſt dexterous are apt to miſtake, and I have experienced the bad effects of employing only one ſower for ſeveral ploughs. A man who goes before each of them will ſow much more equally: nor need he even loſe any of his time, becauſe when he is not employed in ſowing, he may help the women and children to break the clods. The ploughman ſhould always proceed ſlowly and cautiouſly in this firſt tillage, eſpecially if the ground ſeems never to have been ploughed before. If his plough ſhould chance to be ſtopped by any ſtones or roots, which may have eſcaped the endeavours uſed to diſcover them by means of the borer (which ſhould be always had recourſe to as ſoon as the ſurface of the ground is cleared) the other men within call, or even the women and children, muſt immediately take them up with crows, and pick-axes, and carry them out of the field.

Care muſt alſo be taken not to ſpread the aſhes out of the heaps over more ground than can be ſown in the ſame day and the next morning, that they may not be unneceſſarily expoſed to the hazard of loſing their efficacy: but if it ſhould begin to rain, or the ſucceeding day be a Sunday, no more aſhes ſhould be ſpread than can be ſowed and ploughed immediately. Theſe two circumſtances excepted, it will be right to ſpread over night what is to be ploughed in next morning; for I have experienced, that the little nipping froſts in this advanced ſeaſon, will often be ſtrong enough to freeze the aſhes and bits of turf not thoroughly conſumed, ſo as to render them unfit for ſpreading, till the ſun has thawed them; by which means a morning's work might, without this precaution, be loſt.

When the ſeed is ſown and covered, drains ſhould be cut with the ſame plough, either directly acroſs the furrows, or in an oblique direction to them, according as the declivity of the ground may require, in ſuch manner that they may empty themſelves into the main ſurrounding ditches, to carry off the water, eſpecially in the winter. Some of the men employed in breaking the clods will eaſily deepen theſe drains, to whatever degree you may think proper, with an inſtrument ſhaped like a hoe, with a ſtrong flat iron ſpike, about fifteen or ſixteen inches long, on each ſide of it. This inſtrument is very uſeful, and even neceſſary, upon ſeveral occaſions; nor is there any better for ſtirring the ground. It will likewiſe ſerve to complete the breaking up of ſuch parts of the ſpots where the furnaces ſtood, as may not have been ſufficiently cut by the plough; and to finiſh the imperfect ends of the furrows, next the head-lands, where the plough could not reach, and where the grain would be otherwiſe expoſed to the air and birds.

Though the ſpirit and warmth of the ſalts contained in the aſhes, will ſoon render this corn more forward than any other; yet as there will not be among it either graſs weeds, or wild productions of any kind, the ſeeds of all theſe having been deſtroyed by the action of the fire, it will appear thin during part of the winter: but on the approach of ſpring, it will ſhoot up, ſpread, and tiller, ſo as often to become too thick at laſt. It always ripens about a fortnight ſooner than any other corn in the country; and the fineſt, as already obſerved, is conſtantly found on the ſpots where the furnaces were erected; the effect of the fire having been greater, and penetrated deeper in thoſe than in any other places.

As all our riches, as before obſerved, conſiſt in the aſhes, the more there is of them, the more the ground thus broken up will be fertilized. But all kinds of ſoil do not afford an equal quantity of aſhes when burnt; for though the burning be performed with ever ſo much care, repeated experience for ſome time paſt has taught me, that only ſome of the earth and ſtones, according to their quality, are reduced into lime, or calcined, by the operation of the fire, and that other parts of them will run into glaſs. The ſoils that calcine moſt are undoubtedly beſt, and yield the largeſt produce of aſhes,

while thoſe, on the contrary, which burn to a glaſſy ſubſtance, are the worſt, and give the feweſt aſhes. Of this kind is ſand; and indeed, we may judge with certainty of any ſoil intended to be improved by burn-baking, by previouſly making trials on different parts of it. If the owner cannot go thither himſelf, he may order ſome of the turfs cut with a depth of four or five inches of earth, to be brought to him, in order to their being dried and burnt. He may alſo have, in the ſame manner, in bags of paper, properly numbered, ſamples of the ſoil, or of the ſtones underneath, at every ſix inches from the ſurface, to the depth of eight or ten feet. Theſe ſamples may be eaſily procured by means of the borer, already deſcribed under that article.

If the perſon who makes theſe trials be not provided with a borer, holes may be dug. They will not coſt much, and he will be thereby enabled to judge what grain, trees, or other productions, each ſoil is beſt adapted to. I have often practiſed this method with ſucceſs, for improvements which lay at ſuch a diſtance that I could not immediately inſpect them myſelf: but as the judging of lands in this manner, without actually inſpecting them, requires great attention and long practice, the ſureſt method therefore is to examine them on the ſpot, and there make the neceſſary experiments. The furnaces which are the moſt burnt, or thoſe which burn the faſteſt, are not the beſt; for the aſhes are there too much calcined, and their quantity reduced.

I have often ſeen much finer corn grow in places where the uppermoſt turfs of the heaps, which had burnt ſlowly, were only calcined, and remained ſo nearly entire, that it was neceſſary to break them before the ground could be ſowed, than in thoſe places where the furnaces, after being entirely burnt, were totally converted into aſhes. In general, thoſe heaps which produce white aſhes, after they are burnt, are the leaſt valuable, and commonly yield the ſmalleſt quantity. This denotes a greater degree of vitrification than of calcination. In proportion as the aſhes are yellowiſh, brown, or blackiſh, which laſt indicates the greateſt perfection, they are better in quality, and generally more in quantity. According as theſe different colours appear, the calcination exceeds the vitrification. I have dwelt the longer upon theſe different operations of the fire in the burning of land, becauſe they are of great importance to thoſe who break up ground in this manner, and no writers have hitherto given a ſufficient diſtinct account of them, for want of having had the neceſſary experience.

I muſt farther obſerve, that no land ought to be pared again too ſoon after it has been burnt; becauſe its turf being deſtitute of a proper covering, would not take fire well, as I have experienced. It will be neceſſary to wait till the heath or broom has ſhot up ſufficiently, which ſeldom happens in leſs than about two years. The dangerous practice of ſome country people, who frequently ſet fire to their heaths in the ſpring, under pretence of bringing up graſs for cattle, is ſo contrary to the right method of improving land, by burn-baking, that it always retards, and ſometimes abſolutely prevents the execution of this far more beneficial method; eſpecially if thoſe burnings have been too often repeated.

In countries where it is not the cuſtom to plough in ridges, but either in broad lands, or quite flat, in order to ſow afterwards with the harrow, I think it would, however, be right, to ſow the ground thus broken up, at leaſt the firſt year, under furrow, with the two-finned plough already mentioned; after which the uſual method of the country may be followed, if it be found the moſt proper. I adviſe this as the beſt practice, and am ſatisfied that none will have cauſe to repent the trial. It will ſave the greater part of the expence of ploughing; and the aſhes being leſs expoſed to the action of the air, will the more ſtrongly retain their fertilizing power. But, if, notwithſtanding theſe reaſons, the common practice of the country ſhould be ſtill preferred, even in the firſt year, the huſbandman, in this caſe, ſhould begin to ſpread his aſhes in the manner before directed, about Midſummer; as ſoon as the furnaces are cooled, without leaving any in the places where thoſe furnaces ſtood. Immediately after, a ſlight ploughing, juſt ſufficient to bury the aſhes, ſhould be given, with the precautions before-mentioned with regard to the furrows. No more aſhes ſhould be ſpread at any one time, than the plough can cover in the ſame day. A few days after this firſt ſlight ploughing, a ſecond ſhould be given, ſomewhat deeper, in the ſame direction, and theſe ploughings ſhould be continued, each going a little deeper than the former, till the ground be looſened to a ſufficient depth. Two good croſs ploughings will then be of excellent ſervice: after which a fifth ploughing a-croſs them, will bring them up to the direction they were in at firſt. The ground ſhould be harrowed ſeveral times between all theſe ploughings, with harrows heavy in proportion to the ſtrength of the ſoil; and if any hard clods have reſiſted the force of the harrow, women and children ſhould be employed to break them, it being neceſſary to pulverize the ſoil as much as poſſible. I ſay as much as poſſible, becauſe that cannot be perfectly compleated this firſt year. Perhaps the ſpiky roller would be of excellent ſervice here.

The ſame women and children will alſo clear away all the ſtones, if there be occaſion. Each ſucceſſive ploughing will turn the ſtones upon the ſurface; but ſuch only as are bigger than a man's fiſt need be removed. If any of the ſtones ſhould be too large for the women and children to remove, the carters muſt take them up as they paſs by; and if there ſhould chance to be any under ground ſo large that the men cannot move or load them, they muſt be broke with ſledge-hammers, and other iron tools proper for this work; or, if they are great rocks, they muſt be blown up with gun-powder; for nothing ſhould ſtop the progreſs of this undertaking.

The time to ſow the land thus broken up for the firſt time, will always be a fortnight later than the common time of ſowing other lands in the ſame country, with the ſame kind of grain. A few days before this is ſowed, it ſhould have another light ploughing; after which it ſhould be ſowed, in proper weather, with half the uſual quantity of ſeed, whether wheat or rye, and this ſeed ſhould be covered in, either with the plough, or with the harrow. Drains ſhould alſo be cut in this land, in the manner directed under that article, as ſoon as poſſible, to carry off the water in the winter. If any very large clods are left on the ground, women and children ſhould be employed to break them. This land being thus ſowed, nothing more need be done to it till harveſt.

The quality of the land muſt determine what ſort of grain will be moſt proper for the firſt year's ſowing in this huſbandry. If the ſoil be rich, it will bear wheat; if of a middling

middling quality, it will produce meſlin, or a mixture of rye and wheat, conſiſting of a greater or leſſer proportion of either, according to the nature of the ground; and if it inclines to poorneſs, it will produce rye. Theſe particulars may be judged of immediately after the burning. In general, unleſs the ſoil be very excellent, I would always adviſe the ſowing of rye the firſt year. There will be a certainty of ſucceſs with that grain; and the huſbandman will be enabled by its produce, and by the ploughings, to judge what his land will be capable of doing the next year, without running any hazard. This has been my method. I have alſo experienced, that rye does much better than wheat in all light ſandy ſoils thus broken up. When they are afterwards enriched to a certain degree, they become fit to bear meſlin, and then wheat: though if they ſhould never produce any thing but rye, the difference would not be great in point of profit.

As ſoon as the ground is cleared, a light ploughing ſhould be given it, to bury the ſtubble; and ſome days after it ſhould have a ſecond ploughing ſomewhat deeper, but in the ſame direction. When this is done, two good croſs-ploughings ſhould cut the ſoil to the proper depth for ſowing; and a fifth ploughing, afterwards to be given, will leave the furrows in their firſt direction. Between theſe five ploughings, which are to be performed with the plough having only one fin to the ſhare, the ground ſhould be well harrowed ſeveral times, and the ſtones and roots picked out. All theſe ploughings and harrowings will pulverize the earth, and mix it equally with the aſhes. If this land is to remain in ridges, the above will be ſufficient till the ſixth ploughing, which ſhould be given it a few days before the ſowing, and ſhould be followed by the laſt, performed with the two-finned plough to bury the ſeed: but if it be to be ſowed in broad lands, or quite flat, the former directions in that reſpect are to be obſerved here. In whatever manner any of theſe new grounds, broken up with the plough, are ſown, they will not require near ſo many hands to break the clods this ſecond year, as were neceſſary in the firſt. With regard to the quantity of ſeed, a little more may be ſown now, that is, about a third part leſs than is commonly uſed in the country, of the ſame kind of grain, for an equal extent of land.

The lands thus brought into tillage by means of burning, become infinitely better than other grounds, and produce much greater crops. This proceſs improves the ſoil for upwards of twenty years. No weeds will ſpring up among the corn for a conſiderable time; for there are ſcarcely any, even now, in the lands I firſt broke up. The vegetable food in the earth is not therefore waſted here upon uſeleſs plants, but ſerves intirely to nouriſh the corn, which accordingly ſhoots with redoubled vigour, produces well-filled ears, without the trouble and expence of weeding it; and, when threſhed, is ſo clean, that it needs only to be winnowed. The bread made of it is excellent, and of a ſuperior quality. When in proceſs of time theſe burnt-lands ſhall produce as many weeds as other ploughed grounds, they will then be in the ſame degree of imperfection; but it will be a long while before that happens; even longer than I can ſay; for I have not yet ſeen an inſtance of it. The remedy, however, is always ſure and ready, namely, to let them reſt two or three years, by which time they will have acquired a new ſward, thick enough to be pared off, and burnt as before. This will reſtore them to their former perfection, without being near ſo expenſive as the firſt paring and burning: for there will be no roots to grub up here, nor any ſtones to carry off; nor will it be ſo difficult to break the now much fever clods. I have managed in this manner with great ſucceſs, where there has been a ſufficient depth of mould, lands which had formerly been in tillage, and would no longer produce corn becauſe they were exhauſted, either by too many ſucceſſive crops, or too great quantities of weeds. They are now as good as any other burned land.

Worn-out meadows, which I have reſtored by the ſame means, and formed a-new with graſs-ſeeds, have yielded great quantities of excellent hay. I have collected plenty of this ſeed during ſome of the preceding years, from meadows which were not too wet. Several of my neighbours have practiſed the ſame method with equal ſucceſs: and, in a word, it is the moſt powerful reſtorative for worn-out land.

From what has been ſaid, it evidently follows, that the paring and burning of the ſurface of the earth, is, indiſputably, the beſt and ſureſt way, either to clear, or reſtore the ſoil. It is making a moſt advantageous acquiſition to one's own eſtate, the value of which is at leaſt doubled, and oftentimes quadrupled by this means. To enrich one's ſelf, without doing it at the expence of any perſon whatever, and, at the ſame time, to enrich the ſtate, is ſurely an action worthy of a true patriot, and of a reſpectable father of a family. This may be done by following the method here laid down; a method which has been long known, though very ſuperficially. I will venture to ſay, that it never was carried to the degree of perfection to which my practice has brought it; doubtleſs becauſe none applied themſelves particularly to it. *Memoire ſur les Defrichemens.*

A correſpondent of the editors of the *Muſeum Ruſticum* has given us the following method of performing this operation in the fens of Bedfordſhire.

About the middle of May, ſays this gentleman, we plough the land for burning, which is ſward-land, that has not been ploughed for four or five years, or perhaps a longer time: our ploughs are what are called Dutch ploughs, with a large ſhare; the edge and point are very thin and ſharp, and are kept ſo by filing: the furrows ſhould not be more than ſeven or eight inches wide, and an inch and a half thick, having as few baulks as poſſible. When it has lain ſo long that the ſods or furrows are dry (in which the farmer's own diſcretion muſt guide him, it being impoſſible to point that out by words) it muſt be made into heaps about the ſize of middling graſs-cocks, each perſon carrying on before him as heaps about ſeven furrows: the work will then direct him how big the heaps ſhould be; they ſhould be made as narrow at top as conveniently they can, by way of prevention againſt wet weather. If every perſon keeps his work as to the number of furrows, the heaps will riſe in regular rows; but it ſhould be obſerved to keep theſe rows in quincunx order (as repreſented on Plate II. Fig. 7.) that when you come to ſpread the aſhes, they may cover the ground regularly.

When it is fit for heaping, the cuſtomary way of this country is to let the burning out to people, to burn and ſpread the aſhes, which muſt be ſpread ſo as to cover the ground all over: the uſual price is from four to five ſhillings per acre; but that, in a great meaſure, depends upon the dryneſs or wetneſs of the ſeaſon. It would, however, I think, be moſt adviſeable, where hands are plenty, to do this work by the day, as you may then employ as many perſons as you think fit; for it ſhould be burnt off with all poſſible expedition, becauſe if it be long in burn-

ing, it is attended with bad conſequence, which in rainy weather is hard to prevent: it is therefore very requiſite to purſue the work briſkly, otherwiſe the graſs-roots, which lie below the reach of the plough, when ploughed for burning, will ſhoot out, and become almoſt as full of graſs, as though it had not been ploughed at all: then, when you plough it after the burning, inſtead of breaking ſo that the ſeed may fall into the cracks, it will burn up as ſtrait as clay, and then no ſeed can grow any where but in the ſeams between each furrow.

When one ſide of the field is cleared, and the aſhes ſpread, you muſt, as ſoon as there is room, get to ploughing and ſowing the ſeed. Nor muſt the furrows now be wider than thoſe already mentioned, and about two inches deep; for as fen land in general ploughs tough, rather than breaks, you will have more ſeams than if the furrows were made wider: the cuſtom with us is to ſow the ſeed as ſoon as poſſible after the land is ploughed. *Muſeum Ruſticum, vol.* I. *p.* 420.

BURNET, the Engliſh name of a plant, now greatly cultivated as a green food for cattle in the winter. We have given a figure of this plant taken from a ſpecimen gathered in a field belonging to Mr. Rocque at Walham-green, on Plate III. Fig. 12.

It is very natural to think that we have in England many ſorts of graſſes, which are well adapted to the climate, are wholeſome food for cattle, and, with the aſſiſtance of proper culture, would produce very advantageous crops both to the grazier and farmer. We have, for many years, been ſenſible of the great advantages that reſult from the culture of ſaintfoin: in ſome ſoils lucern has been ſown with conſiderable profit, and the Dutch treſoil is known to be excellent, when properly managed: but theſe only ſerve for green fodder in ſummer: they may, indeed, be dried, and made into hay, and in that form be reſerved for the cattle's food in winter; but this, independent of the inconvenience, trouble, and uncertainty, that attend the making and keeping it in proper order, is not ſufficient; the farmer has alſo occaſion for green fodder in the winter, and early in the ſpring, and that on many accounts, particularly for feeding ſuch of his ewes as will yearn early in the year, as well as keeping them from loſing their fleſh after they have dropped their lambs.

A plant therefore which will not only live through the winter, but will alſo, if poſſible, vegetate in that ſeaſon, cannot fail of being highly advantageous, provided it be at the ſame time a pleaſing and nouriſhing food for cattle. All theſe properties have been lately found in burnet; it not only preſerves its verdure during the hardeſt froſts of our winters, but alſo increaſes in bulk, and grows, if the weather be at all open and mild; and is now known to be an excellent food for cattle. This diſcovery is owing to Mr. Rocque of Walham-green, who, at the requeſt of the late Mr. Wyche, ſpent ſome years in endeavouring to find a plant that would prove an uſeful and ſucculent food for cattle during the winter; and, at laſt, fortunately diſcovered that burnet would anſwer the intention.

Mr. Rocque has alſo found by experience, that it will grow in the drieſt land: for he has planted ſome of it even in the gravel walks in his garden, where every thing elſe is burnt up in the ſummer, but this never withers; one of the qualities of burnet being to continue in ſap all the year. It is the opinion of many, who have ſeen the burnet of his raiſing, that if this plant is generally cultivated, there will never be a ſcarcity of hay in England, even in the greateſt drought.

The land, on which it is ſown, ſhould be fine, becauſe it is apt to ſhed, and it ſhould afterwards be dried perfectly.

Burnet does not loſe its leaves in drying; and though the hay made of it be ſticky, it will, after threſhing, be very agreeable to horſes, which are ſo fond of it, that they never waſte any. One acre will produce upwards of three loads of hay, and above forty buſhels of ſeeds. Horſes are fonder of this ſeed, than they are of oats: and Mr. Rocque is of opinion, that it is a more proper food for thoſe who do not labour hard, becauſe it is not of ſo hot a nature. Burnet bears ſeed twice a year, and will afterwards yield a good ſpring crop.

It is not only good for horſes, but alſo for all manner of cattle, even for ſwine: and Mr. Rocque has experienced another virtue in it, which is, that, being ſtung by a waſp, the leaves of this plant rubbed pretty hard upon that part ſo injured, immediately took off the inflammation.

If the burnet does not grow equally every where, ſome plants muſt be drawn where they are too thick, and planted where they are thinneſt: or the vacant ſpaces may be ſupplied from the nurſery. If the land was not got in good order to ſow the ſeeds at a proper ſeaſon, the burnet may be tranſplanted at Michaelmas from this nurſery, and ſet at nine or twelve inches diſtance every way, according to the richneſs of the ſoil.

The ſeed ſown in May may be mowed at the latter end of July. That ſown in June will yield a pretty good crop, and muſt be cut but once; and the ſame of that which is ſown in July. The plants produced by ſeeds ſown in Auguſt ſhould be mowed, to deſtroy the weeds. Theſe mowings may either be given green to horſes, or made into hay. The firſt ſpring cutting will purge horſes; and Mr. Rocque believes it will alſo cure the greaſe: but it is only the firſt crop that purges.

Burnet ſhould be mowed but once the firſt year, in order to leave it rank in the winter; and in this caſe it will be ready to feed in February or March, or to mow again in April.

If natural graſs grows among the burnet, it may be harrowed in the ſame manner as lucern; for having a tap-root, the harrow will not hurt it: but it muſt not be ploughed, leſt the roots ſhould be broken in the ground.

When the ſeeds of this plant are to be ſaved, it muſt neither be fed, nor mowed, in the ſpring. The ſeed will be ripe about the middle of June, when it muſt be reaped like wheat, and threſhed on a cloth. It ſhould be threſhed before it is too dry, becauſe it is apt to ſhed, and it ſhould afterwards be perfectly dried.

As a great deal has been written on the ſubject of burnet, we ſhall endeavour to ſet the whole in a fair light, by adding two letters which have been ſent from gentlemen of known character and reputation, to Dr. Templeman, ſecretary to the Society of Arts, Manufactures, and Commerce. The firſt is from Davies Lamb, Eſq; and was ſent in conſequence of a letter ſent that gentleman by a member of the ſociety, requeſting his opinion with regard to the uſefulneſs of burnet.

" My burnet, ſays Mr. Lambe, though very green and beautiful all the winter, made no great progreſs till the middle of April following, when I thought it abſolutely neceſſary to feed it. I did ſo, but I did it too late, and kept

kept my cattle upon it too long, from the middle of April to the 20th of May. This was a very great miſtake; the burnet plants were now headed for ſeed, and the flock chiefly fed upon the heads, which greatly leſſened my quantity of ſeed, as well as retarded the growth of the plants. I turned into the field, ewes, lambs, and calves, and they all fed very greedily upon the burnet. From what I had heard of Mr. Rocque, I very much expected them to ſcour, but there was not the leaſt appearance of it, and the cattle throve accordingly.

The 6th of July I began to mow, the weather being favourable; ſix men and four boys threſhed and cleaned the ſeed in ſeven days. I had 200 buſhels of very fine clean ſeed, as many ſacks of chaff, and ſeven loads of hay, from a field of ſeven acres and a quarter.

Satisfied that 200 buſhels of ſeed would be more than I ſhould be able to diſpoſe of, I was not anxious after another crop, being rather deſirous of ſeeing what it would perform as a paſture. Accordingly, in about ten or twelve days after the field was cleared, I turned into it ſeven cows, two calves, and two horſes; they all throve very remarkably, and the cows gave more, and we thought a richer milk than in any other paſture; I really expected, (as burnet is ſo ſtrong an aromatic) that the milk would have had a particular taſte; but far otherwiſe: the milk, cream, and butter, were as fine, if not finer taſted, than any from the beſt meadows. I am ſatisfied, that there is no better paſture for cows, whether milch or barren, than burnet. The weather was now extremely droughty, all our paſtures were burnt up, yet the burnet flouriſhed, and grew away, as if it had a ſhower every week. My ſtock of cows, horſes, and calves before mentioned, paſtured in it almoſt continually, till Michaelmas; by the middle of November it was grown ſo conſiderably, that I have again turned in ſix head of cattle, and if the weather is not ſevere, I am of opinion, it will maintain them till Chriſtmas.

The burnet ſtraw, or haum, is, after the ſeed is ſeparated from it, a very uſeful fodder for horſes, cows, calves, and ſheep; the chaff is of good value, if mixed with any other, however, ordinary, chaff. I have fed all the above-mentioned ſtock with it promiſcuouſly together in one field; putting the haum into racks, and the chaff into troughs, and if the haum was chopped with an engine, it would ſtill be of much more value.

Burnet, I am fully perſuaded, will prove a very great acquiſition to huſbandry on many accounts, but more particularly for the following reaſons:

Burnet is a good winter paſture, conſequently it will be of great ſervice to the farmer as a conſtant crop he may depend upon, and that without any expence for ſeed or tillage, after the firſt ſowing: whereas turneps are precarious and expenſive, and when they fail, as particularly this year, the farmer is very often put to great inconveniencies to keep his ſtock.

It affords both corn and hay too. Burnet-ſeed is ſaid to be as good as oats for horſes. I know they will eat it very well; judge then the value of an acre of land, which gives you at two mowings ten quarters of corn and three loads of hay.

The ſeed indeed is too valuable to be put to that uſe at preſent; though it multiplies ſo faſt, that I doubt not but in a few years the horſes will be fed with it.

It will bear paſturing with ſheep.

It makes good butter.

It never blows or hoves cattle.

It will flouriſh upon poor light ſandy, ſtoney, ſhaltery, or chaulky land.

Burnet, after the firſt year, will weed itſelf, and be kept clean at little or no expence.

The cultivation of burnet is neither hazardous nor expenſive: if the land is prepared as is generally done for a crop of turneps, there is no danger of any miſcarriage; and any perſon may be ſupplied with the beſt ſeed at ſixpence per pound, by Mr. Charles Thorp, ſeedſman, in the White-Hart-Inn-yard, Borough.

I make no doubt but that burnet might be ſown late in the ſpring, with oats or barley. A gentleman in my neighbourhood did ſo laſt ſummer, and it ſucceeded very well. I ſhould think a buck-wheat ſeaſon, which is ſown the laſt of all corn, would ſuit it very well; but of this I have no experience, and could wiſh to have the experiment tried. A pea-field, drilled in rows, and kept clean, would make an excellent ſeaſon for burnet, as the pea drop would come off ſoon enough to prepare the land with two ploughings by the middle of Auguſt, after which time I ſhould not chuſe to ſow it.

It very frequently happens, that every farmer who ſows many acres with turneps, has ſeveral worth little or nothing; the fly, the dolphin, the black caterpillar, the dry weather, or ſome unknown cauſe, often defeating the induſtry and expence of the moſt ſkilful farmer. When this happens, as it too often does, I would by all means adviſe him to ſow it with burnet, and in March and April following, he will have a fine paſture for his ſheep and lambs.

Burnet is a native of England, and will certainly perfect its ſeed twice in one ſummer; and a farmer, with a ſmall plantation, may ſupply himſelf with ſeed of his own growth at very little or no expence: he may then be encouraged to make experiments on various ſeaſons, without much loſs or damage.

Thus, Sir, I have ſent you a true account of the ſucceſs of my burnet, and alſo my opinion of it. I wiſh what I have ſaid may any ways contribute to diſpel the prejudice, or inform the ignorance of my countrymen."

The other letter is from Chriſtopher Baldwin, Eſq; of Batterſea, a gentleman well known, and juſtly reſpected for his candor and fidelity.

"In the years 1763 and 1764, ſays Mr. Baldwin, I made ſeveral experiments on burnet, with a view to make myſelf acquainted with its manner of vegetating, and the uſes to which it might be applied: and having by this means acquired that knowledge I was deſirous of attaining, I determined laſt year to lay down ſeveral acres with burnet; nor would I content myſelf with doing it in any one particular method: therefore in the beginning of July, 1764, I ſowed about eight rod of ground with five pounds of Rocque's burnet ſeed. Rain falling ſoon after the ſeed was ſown, the plants came up very finely, and throve in ſuch a manner, that I was tempted to plough up about an acre of ground and plant it that autumn, in order to ſee what effect the winter would have on the young plants. Accordingly on the fourth of October I planted them in rows, about twenty inches apart, and about fifteen inches from each other in the rows. This diſtance, from experiments and obſervations which I have made, ſeems to me a very proper diſtance. Theſe plants took very well, and through the winter

winter throve with ſurpriſing vigour. Laſt ſpring I ploughed the remainder of the field, being three acres, and planted it in the ſame manner with my plants, the whole of which, notwithſtanding the uncommon drought of laſt ſummer, grew well, and the verdure of the plants was really very beautiful. No water was uſed; indeed it would have been a vaſt work in a field of that ſize: however, I never ſaw any need of it. The plants were once hoed, and ſtood over for ſeed, of which the quantity collected was not very great; but this muſt be attributed to the uncommon drought, for I think we had not above one ſhower of rain from the planting to the gathering of the ſeed, the whole of which amounted to about 160 pounds.

The ſeed being got, I was impatient to ſee how the cattle would take to it, as it was roundly aſſerted by ſome gentlemen, that no cattle would eat it. Accordingly I ordered four cows and two horſes to be turned into the field; the cows fed freely upon it, but the horſes did not ſeem to like it ſo much at firſt, though in two or three days they fed well upon it. Burnet has ſtrongly the taſte of cucumbers, and I was fearful it might give a diſagreeable taſte to the milk; it therefore gave me great pleaſure to find, in about four or five days, that the quantity of milk was not only much increaſed, but the flavour of the cream much ſuperior to any I had ever had before, or ever taſted from cows fed upon the richeſt meadows. The cows and horſes having fed down the field, it was hoed again, and then harrowed once over, which laid it very clean, nor could I find that the burnet was at all hurt by the harrow.

Here let me obſerve to you, that I fed my horſes in the ſtables for about five weeks with the burnet ſtraw, or rather haum, from which the ſeed had been threſhed. Theſe horſes fed very freely, and throve much upon it, though they had only half their uſual allowance of oats. However, as I would by no means ſecrete any circumſtance that may appear unfavourable to burnet, ſo I muſt tell you that I obſerved, when any friend called upon me, and their horſes were put into the ſtable, that ſome horſes eat very greedily of it, and others would not touch it. I cannot ſay this gave me much concern. I ſatisfied myſelf with thinking, that ſome horſes did not know what was good for them; or to ſpeak more ſeriouſly, I thought the novelty of the food might as much diſpleaſe one horſe, as it pleaſed another; and doctor Templeman knows, that there are ſome things which we loath as children, that we are fond of as men; and that there are ſome things which we as much diſlike as men that are very wholeſome food: but to come nearer to the point. It is well known ſome ſheep and cows will not touch a turnep, yet is any one weak enough to infer from thence, that turneps are an unwholeſome or an improper food for cattle? And I was lately told by a particular friend, that he had often obſerved, when his horſes had fed for ſome time on the ſaintfoin hay, that it was ſome days before they would again take to meadow hay. I ſhould not have mentioned this circumſtance of the horſes, but to ſhew my impartiality; and I do it the more readily, as I find there are ſome gentlemen who are as fond of decrying, as others can be of promoting, uſeful experiments in agriculture.

Being well pleaſed with the ſucceſs that had attended my firſt experiments in the field, which I call four acres, I determined to proceed as I had intended in the ſpring of the year; accordingly as ſoon as the oats were got off a field of twelve acres, I ordered it to be ploughed and ſown with 160 pounds of burnet ſeed before mentioned. This field was ſown on the twenty-ſixth of Auguſt laſt; and no rain falling till the eighteenth of September, the plants did not appear till the twenty-eighth of that month: however, there ſeems to be a good crop, and I intend as ſoon as they freſh up in the ſpring, to have the plants ſet out with ſmall hoes (ſuch as are uſed for carrots and onions) to about ſix inches apart. And in about a week after this is done, I ſhall harrow it with light harrows; for from experiments which I have made, this ſeems to me to be the beſt method of managing broad-caſt burnet. Having nothing farther to ſay in regard to theſe twelve acres, I muſt return to the four acre field tranſplanted, which having been hoed and harrowed as before-mentioned, was laid up for winter food for my cows; but finding lately ſome gentlemen had again aſſerted, that ſheep in particular would ſooner feed on the quick-hedges than touch the burnet, I ſent to a neighbouring farmer for his flock of ſheep, and having a friend with me, we followed the ſheep into the field, who fell upon the burnet ſo greedily, that we found it very neceſſary to ſend them home again.

Being much vexed at theſe idle tales told about ſo much to the prejudice of this (as it appears to me) excellent plant, I determined to put it to as fair a trial as I poſſibly could. Accordingly, I ordered in four cows, which were in a very good feed on natural graſs, and had beſides a large truſs of oat-ſtraw put in their cribs, every night, notwithſtanding which they gave very little milk, and indeed were almoſt dry. Theſe cows, I declare, had not been in the burnet above ſix days, before they gave much more than double the quantity of milk; nay was I to ſay three times the quantity, I know I ſhould not exceed the truth. The milk is exceeding fine, and free from all bad taſte: and further I muſt obſerve, that they ſoon began to leave half their ſtraw in their cribs; ſo that they are now ſerved with only half the quantity they had before. My land is a poor dry upland gravel; there are millions of acres in this kingdom of better land that do not fetch two ſhillings and ſixpence an acre. What a field therefore is here for improvement! Nay, I cannot but obſerve with amazement, the great numbers of country gentlemen who daily flock to this great city in purſuit of trifles, when they have ſuch inexhauſtible funds of knowledge within themſelves, if they would properly make uſe of them: confident I am, I could point out methods of improvement that would ſurpriſingly better their eſtates.

As the account I have now given you of burnet may appear a little extraordinary to ſome of the worthy members of your ſociety, ſo I ſhall be far from being diſpleaſed at their even doubting what I have now ſaid: on the contrary, it will give me pleaſure, provided any gentlemen, who have ſuch doubts, will do me the favour to call at my houſe, and convince himſelf by occular demonſtration of what I have now ſaid."

BURNING *of heath*, a common practice of the country people for clearing heathy ground, in order to procure graſs and herbage for their cattle.

The fitteſt time for burning commons is towards the latter end of the ſummer, when the plants are withered. But great care muſt be taken that the fire extends no farther than is intended.

This

This care conſiſts chiefly in clearing away all the graſs, &c. on the ſide you would preſerve from the flames, to a diſtance ſufficient to prevent all communication. The graſs, &c. cut down there ſhould be ſpread upon the part intended to be burnt, which will ſerve to kindle the fire after it is dry.

Beſides this precaution, a fair, calm day muſt be choſen; when by kindling the fire on the ſide the wind blows from, you prevent its ſpreading any further that way, and ſee it gradually remove up into the heath or common. The fire ſhould be carefully watched for fear of accidents. But, if notwithſtanding theſe precautions, it ſhould ſpread to places intended to be preſerved, and no water ſhould be at hand, the moſt effectual way of ſtopping the progreſs of the fire, is to dig a trench: for by throwing up the earth on the ſide where the fire is, you cover the graſs, and thereby hinder the flames from extending any further.

BURNING *of land.* *See the article* BURN-BAKING.

BURNS, are accidents that often happen to animal bodies, whereby a ſolution of the continuity of the parts are produced.

In burns and ſcalds, when the ſkin remains entire, let the part be bathed well, and kept wrapped up in rags dipped in ſpirit of wine camphorated. Salt bound thick on the part has alſo been found very effectual for this purpoſe. Indeed all ſaline and ſpiritous applications excel all others, while the ſkin is yet unbroke; but when the ſkin is ſeparated, anoint the part, and keep it conſtantly ſupple with linſeed or ſallad oil, and a plaſter ſpread with bees-wax and oil. If the ſkin be ſo ſcorched, that ſloughs muſt be digeſted out, dreſs the wound with the wound-ointment and oil of turpentine, and finiſh the cure with any drying ointment.

The fire ſuppoſed to be left in the part after injuries of this kind, is nothing more than the inflammation, which is the natural effect of ſuch cauſes: ſo that the whimſical notions and conceits concerning fire remaining in the part, is extremely abſurd. *Bartlet's Farriery, pag.* 251.

BURNT-CLAY, a manure proper for cloſe compact ſoils, which it opens, warms, and invigorates, and thereby diſpoſes ſuch lands to part with their vegetative virtues.

A correſpondent of the editors of the *Muſeum Ruſticum*, tells us, that he has experienced the efficacy of this manure on wet, cold land; and gives the following method of preparing it.

"I cauſed, ſays he, a labourer to dig as much clay as made a number of walls nine inches high, the ſame in thickneſs, and placed at the ſame diſtance from each other, in the ſame parallel direction, forming a ſquare of about three yards. Theſe vacancies, being like tunnels of brick kilns, I filled with bruſh-wood, and on that threw ſome cinders or ſmall coal, of which I had ſufficient quantities, living then near ſome collieries; after which I covered the whole ſquare with clay about three inches thick, leaving the ends of the tunnels open, which I then lighted on the windward ſide: as ſoon as the fire had got ſufficient head, I ſtopped the mouths of them; and when I perceived the covering was almoſt burnt through, I had a ſmall ſprinkling of cinders or ſmall coal thrown on the heap, and then another covering of clay of the ſame thickneſs; and thus I went on till my fire was ſeven or eight feet high.

"When I found my fire was very well kindled, which was commonly about the time I put my ſecond coat on, I uſed to enlarge the baſe of the fire, by continuing the tunnels, and by adding new ones to the ſides (which were filled and covered as the others, and then lighted) till I made my fire about ſeven yards ſquare; for I ſoon found it never burnt well in the middle, if it was too large at firſt.

"Care ſhould be taken that the labourer does not put on too thick a coat at once, as it will be apt to ſmother the fire: beſides, by confining the heat in too much, the clay was apt to run and vitrify, which was then of little uſe.

"As ſoon as the heap was ſufficiently cool (for the ſooner it is laid on the land the better) I put about ten large cart loads on a ſtatute acre, and found it an admirable manure for either meadow, paſture, or corn; for the latter it will not laſt longer than three crops, though longer for the two former: and with this I have made prodigious improvements; but I do not believe it will anſwer for a ſandy ſoil, as it will render it ſtill lighter.

"This manure I burnt all times of the year, though ſlower in the winter than ſummer, but always faſteſt in windy weather.

"This I fancy may be burnt with bruſh-wood, or furze only; which I apprehend will anſwer better between the coats than coal, as it will keep the clay more open." *Muſeum Ruſt. vol.* I. *pag.* 407.

BURNT-*grain*, a diſtemper common to corn, and too often confounded with ſmut, though it is, in fact, very different, and much more dangerous.

The ſmut, properly ſo called, occaſions the total loſs of the diſtempered ears; but as the black duſt is very fine, and the particles of it have no coheſion, the wind and rain carry it off, ſo that ſcarcely any thing is houſed in the barn, &c.

The burnt-grain is, on the contrary, often laid in the granary with that which is ſound, to which it communicates a contagious diſtemper, and alſo darkens the flour, and gives it a bad ſmell.

The characters of this diſtemper are, 1. The plants that produce burnt ears are ſtrong and vigorous.

2. The infected ears are not at firſt diſtinguiſhable from thoſe that are healthy; but when they are paſt their bloom, they appear of a deep green colour, approaching to blue; they afterwards become whitiſh, and are then eaſily known. As this change of colour is effected by the ſun, when a number of white ears have been ſuddenly perceived in looking over a wheat-field, the ſun's heat has been often thought to cauſe this diſtemper, or a fog preceding that heat.

3. Though all the ears produced from one grain are commonly infected, yet M. Tillot, Aimen, and myſelf, have met with ſound ears on plants that had produced others which were infected. We have even found ſome ears, part of which only were vitiated, and finally ſome grains encloſing partly a white flour, the remainder black duſt.

4. In burnt ears, the chaff, or outward coat, was commonly found, with this ſingle difference, that when the ears were near ripe, it appeared more withered and dry than in the healthy ears.

5. The bran, which immediately encloſed the grain, is not deſtroyed, as it is in the ſmut, properly ſo called; but has conſiſtence enough for the grain to preſerve nearly its natural form, with a whitiſh look.

6. The burnt grains are ſhorter, rounder, and lighter than ſuch as are uninfected: they are ſometimes larger,

ſome-

ſometimes ſmaller. The furrow which runs the length of a grain of wheat is ſometimes totally effaced, at others is viſible: the piſtils at the extremity of the grains are dried up.

7. The bud of burnt-grains is not viſible.

8. Till the blooming ſeaſon, there is very little difference betwixt the burnt-grain and that which is healthy: they are only a little more ſwelled. But, in the blooming ſeaſon, the infected ears aſſume a bluiſh colour; the chaff is more or leſs ſpecked with ſmall white ſpots: the grains are of a deeper green, and larger than a ſtate of nature; and, as long as they preſerve that colour, they adhere ſtrongly to the chaff. The diſtemper has often attacked very young ears, while yet encloſed in the ſheath. The ſtamina on the ſides of the grain are then dried up and ſickly; the embrio in part takes the deep green colour above-mentioned; the infected ears have not the conſiſtence of thoſe that are healthy; in the ſame meaſure the diſtemper advances, the chaff becomes dry and whitiſh.

9. The grains have ſome degree of firmneſs. On opening them, which may eaſily be done with the nail, there appears an unctuous, dark, brown, ſtinking ſubſtance, not at all reſembling the light duſt of ſmutty ears; the duſt of burnt-grain has ſome coheſion, and through a microſcope appears to conſiſt of larger particles than that of the ſmutty ears.

10. Some time before the blooming ſeaſon, the grains appear to be filled with a whitiſh ſubſtance, a little burnt towards the bottom, and this colour extends by degrees over the whole ear: the grain then appears divided, as it were, into equal quarters by furrows; which diſappear as the grain increaſes in ſize.

11. By what has been ſaid, it is evident that ſmut infects corn much ſooner than the burnt-grain.

12. Grains that are much burnt are evidently incapable of ſprouting. But I have had ſome ſound grains taken from an ear greatly burnt, which, in a kitchen-garden, have produced very ſtrong plants; and though the birds diſturbed my experiment, it appeared to me that there were ſome ſound ears among many more that were infected.

13. A part of the burnt-grain is bruiſed by the flail, and their black duſt is ſcattered over the ſound grain; this unctuous duſt chiefly ſticks to the hairy extremity of the grain near the bud; it there forms a black ſpot. Corn ſo affected, is called *ſpotted grain:* many of the grains which eſcape the flail remain entire, on account of their lightneſs; a great deal is ſeparated by throwing, but the ſpotted grain remains as well as many that are burnt; and this is enough to darken the flour, and give it a bad taſte.

14. To remedy this inconvenience, and make the beſt bread, they paſs the corn through drum-ſieves (*cribles à tambour*) made of pierced iron-plates, like the graters with which they raſp tobacco; the corn is then waſhed, and all the light grains that ſwim ſkimmed off, which are moſtly burnt. The water takes off the ſpots, which are but ſuperficial; for if a ſpotted grain is wiped, the ſpot immediately diſappears.

With reſpect to the cauſe of this diſtemper, I confeſs we are hitherto as much at a loſs as in the caſe of ſmut. Some have attributed it to dung; others to fogs; many to the heat of the ſun; ſome to inſects; others to the moiſture of the land; and not a few to the ſeed not being ripe: but theſe opinions are confuted by good obſervations, and by experiments very carefully made. We refer to what has been ſaid of ſmut.

It may ſeem improbable that a meer ſuperficial duſt, that only ſticks to the bran, without penetrating the grain, ſhould be ſo contagious as to infect all the grain it touches, with a diſtemper; what is more ſurprizing is, that it ſhould injure the organs of fructification only. Yet, however improbable this may appear, the experiments made by Monſ. Tillet put it paſt a doubt; they ſhew that the farmers are not without reaſon cautious in avoiding to ſow ſpotted grain.

As it would take up too much room to mention, at large, all the experiments made by M. Tillet, which are to be found in the papers publiſhed by him on that ſubject, I ſhall content myſelf with relating the reſult of theſe experiments, and the inferences this able naturaliſt draws from them.

Several writers having mentioned dung as the immediate cauſe of this diſtemper, and others having aſſerted that it was hereditary, all M. Tillet's experiments were calculated to clear up theſe two points: he was at the ſame time in hopes, by means of the ſame experiments, of finding ſome method of guarding againſt this terrible diſtemper.

1. The ſeveral kinds of dung had no viſible effect in producing burnt-grain. The infected ſeed produced as much burnt-grain in the ground that was not dunged as in that which was. He did not find that dung had any effect, either in favour of, or againſt the diſtemper.

2. Dung made of the ſtraw of infected grain, did not ſeem to communicate the diſtemper; but the infected ſtraw unrotted ſeemed to communicate it. Yet the effect was moſt viſible when the duſt of burnt ears was mixed with the earth.

3. All grain naturally ſpotted, whether it grew on the land, or was brought from another place, bearded-wheat, ſummer-wheat, and wheat without awns, produced a great deal of burnt-grain.

4. Picked wheat taken from the fineſt ears, and carefully ſelected grain by grain, that none of it might be infected, being ſowed, ſome in dunged, and the reſt in undunged beds, without having received any preparation, yielded little or no burnt-grain.

5. Some of this ſame picked wheat being ſprinkled with the duſt of burnt-grain, produced as many diſtempered ears as that which was naturally ſpotted.

6. The picked wheat, being prepared with lime and a ſolution of the ſea-ſalt, yielded ſtill fewer infected ears than when unprepared.

7. There were ſtill fewer from what was prepared with lime and nitre.

8. Early or late ſowing ſeemed to be a matter of indifference.

9. It appears by M. Tillet's experiments, ſeveral times repeated, that the duſt of burnt ears is contagious, ſince ſound wheat ſprinkled with it, or ſowed in rills in which that duſt had been put, produced a great number of infected ears. He alſo found that this duſt, though expoſed to a ſtrong heat, as of ſixty degrees, is ſtill contagious, unleſs it is abſolutely burnt by the fire, when it has not that effect. Though it is kept for years, its infectious quality continues as ſtrong as ever.

10. Some farmers waſh the ſacks in which they put their

their ſeed. And it appears by M. Tillet's experiments, that they are in the right; for if the ſacks had any of the duſt on them, it would certainly infect ſome of the ſeed corn.

11. M. Tillet thinks he has obſerved, that the infected plants are more ſuſceptible of injury from froſt than others.

If this is the caſe, hard froſts muſt be ſerviceable, ſince by deſtroying the infected plants, they would have the ſame effect, as if ſuch plants had been all pulled up. The land being cleared of theſe uſeleſs plants, would be better able to ſupply ſuch as are found with nouriſhment, and the crop would be exempted from infected ears, which are a great hurt to it.

12. The black duſt ſo contagious, is not ſo to rye or bere; but the duſt of darnel is pernicious to wheat.

13. Smyrna wheat is leſs ſubject to this diſtemper than other grain; but ſummer wheat is greatly injured by it.

It muſt be allowed that the knowledge which has been acquired of the cauſe of this diſtemper, has put the curious obſervers in a train of finding proper preſervatives. In fact, as the duſt of burnt-grain infects all the grain it touches, it is probable that every method ſhould be deemed efficacious, that is capable of taking away this duſt, provided the virus has not from its firſt contact affected the interior part of the ſeed intended to be ſowed. In this caſe the ſeveral ſieves which we have recommended to be uſed in the preſervation of corn, and the waſhings with fair water, which in many places is uſed on ſpotted grain, may be mentioned as efficacious preſervatives, as well as lime-water which our farmers uſe, the ſtrong brine uſed in ſome provinces of France, and the ſolution of arſenic, of which ſome perſons have made ſuch a ſecret: all theſe preparations ſhould be of ſervice; and, according to M. Tillet's experiments, they are ſo: yet they are often inſufficient. This point, therefore, merited to be cleared up by particular experiments, and with all neceſſary care. M. Tillet ſet about it with ſpirit, and the following are the inferences that may be drawn.

1. The effect of the black duſt on the ſeed is only ſuperficial till it is put into the earth, not at all affecting the interior parts.

2. Therefore every means that can tend to clear them of the duſt, muſt be of ſervice to keep them healthy, and free from the diſtemper.

3. Grain perfectly free from this, and from rottenneſs will yield no diſtempered plants.

4. Grain blackened with this infectious duſt, may be made healthy by clearing it of ſuch duſt.

5. Sifting ſeed, and waſhing it in ſeveral waters, leſſen, it is true, the effects of the contagion; but this is not ſufficient, as many infected plants will be produced, though the ſeed was waſhed in ſeveral waters.

6. Lime, which is more efficacious than water, is not always enough ſo. I ſhall obſerve, on this occaſion, that ſeed was formerly limed in a manner different from what it is now. The ſeed was then put into baſkets, which were plunged into lime-water very hot. The ſeed was ſtirred in the baſkets, and all that ſwam on the water was taken out with a cullender; by this means they got rid of the infected grain; and the good ſeed was better cleaned, than by only throwing, as they do now, lime-water on a heap of ſeed, which is then ſtirred with a ſhovel, or by only mixing the ſeed with the ſlacked lime reduced to powder.

One of our farmers, a careful man, being obliged one year to ſow ſpotted ſeed, he limed it by immerſion, in the manner above deſcribed; and the year following had no burnt-grain.

Some experiments made in the county of Caux, by M. de Goufreville, have been publiſhed; they evince the good effects of lime uſed in the manner we have mentioned. And what is ſtill a farther confirmation of this is, that whenever our farmers ſow ſeed that has not been limed, their fields are amazingly infected.

7. It is a good precaution to waſh ſpotted grain in ſeveral waters; but it ſhould be ſoaked in brine, and this brine ſhould be abſorbed by lime, by immerſion, as we have deſcribed.

8. A ſtrong brine of ſea-ſalt is very good, and may be employed to great advantage in countries where ſalt is a merchandize.

9. One part of nitre to nine parts water is more efficacious than ſea-ſalt; this, therefore, ſhould be uſed where nitrous earths abound.

10. Strong alkaline lyes are ſtill better; ſalt wort, pot-aſh, aſhes of tartar, lyes of common aſhes much impregnated with ſalt and human urine, or cows urine, alkaliſed by putrefaction,: of theſe various articles ſuch may be choſen as are moſt common. For inſtance, in Normandy aſhes of ſea-wrack, which are very cheap there, may be uſed. This, which is rejected for dying and lyes, as being more impregnated than alkaline with ſea-ſalt, may be advantageouſly uſed in the preparation of ſeed.

11. As it is evident that ſeed picked with care yields very few infected grains, it muſt, of courſe, where a farmer has ſpotted grain, be of great advantage to him to change his ſeed, in order to procure what is uninfected.

12. M. Tillet's proceſs may be comprehended in what follows: if the ſeed is ſpotted, it ſhould firſt be waſhed in ſeveral clear waters, till the black is quite got off; it ſhould then be put into the ſteep. If it is not ſpotted, ſoaking it in the following liquor will be enough. Make ſome lye, ſuch as is uſed for linen, in a bucking-tub, putting four pound of water to every pound of aſhes. If one hundred pounds of aſhes are uſed and four hundred pounds of water, there will be two hundred and forty pounds of lye, to which muſt be added fifteen pounds of lime, which will be enough to prepare ſixty French buſhels of wheat (between ſixteen and ſeventeen buſhels Engliſh meaſure). When this ſteep is to be uſed, it muſt be heated as hot as you can bear your hand in it; the ſeed, being put into baſkets, muſt be plunged into it, and ſtirred with a ſtick; the baſkets muſt then be raiſed and kept up by ſticks on the edge of the bucking-tub for the lye to drain; the ſeed being thus prepared muſt be laid on the floor of the granary till it is dry enough to ſow. If it is prepared long before it is wanted, it muſt be, from time to time, ſtirred with a ſhovel to prevent its heating; with this precaution it may be kept a month, or even a whole year.

We prepared ſome ſeed in this manner at M. Taponat's, near Rochefoucault in 1760; and in 1761 we ſaw with pleaſure that the corn ſo prepared was uninfected; whilſt in the neighbouring fields, a fourth, a third,

and even half the crops were ſpoiled by this diſtemper.

All the trials that have been made evince that acrid ſubſtances are proper remedies for this diſtemper: I alſo believe all the ſteeps to be good; but preſer M. Tillet's, as being more acrid, and leaſt coſtly. I imagine lye that had been uſed for linen might do, only ſtrengthening it with ſome ſea-wrack, and putting twice as much lime. I know this lye to be very acrid, but cannot anſwer for its efficacy in preſerving corn from being burnt, becauſe for ſeveral years paſt we have ſcarcely had any of our grain ſo infected.

13. Several farmers in different provinces have uſed a ſolution of arſenic to prepare their ſeeds. Great complaints have been made in all quarters of it. Among others, a phyſician publiſhed an Eſſay to ſhew of how much importance it was to prohibit the uſe of this poiſonous ſteep. He there enumerates all the accidents that have happened to the ſowers, and to the men that made the preparation, of which himſelf was a witneſs. Since M. Tillet has given us a method ſimple and innocent in itſelf, but little coſtly, and of great efficacy to clean ſpotted grain, it is to be preſumed that no body will uſe this pernicious drug, from which ſuch melancholy conſequences may enſue, if by accident any of it ſhould be mixed with the meal, and if the light corn is given to the poultry or cattle; beſides, this poiſoned ſeed muſt kill all the partridges and pigeons that eat the uncovered grain.

As ſome people are fond of making objections, it may, perhaps, be urged, that if the black duſt was ſo infectious, this diſtemper would make from year to year ſuch progreſs, that in the end we ſhould have nothing but burnt-grain. But we need not be apprehenſive in this reſpect; and a year in which much corn is infected, ſucceeds one in which ſcarcely any burnt-grain was to be met with. Scarcely any was to be found in the crops of 1754, 1760, and 1761.

In reflecting on this objection, which has ſome weight, I think I have found an anſwer to it in M. Tillet's obſervations, which is, that hard winters, paſt all doubt killing the diſtempered plants, ſtop its progreſs.

It may alſo be ſaid, that if this diſtemper is only cauſed by the infectious duſt, how can it at firſt get footing in a province that was before unacquainted with it?

It is readily allowed that this diſtemper may be attributed to other cauſes beſides the black duſt: but M. Tillet's experiments inconteſtibly prove this duſt to be contagious: and his reſearches ſupply us with the means of leſſening conſiderably, if not entirely extirpating this diſtemper: thus we may have larger crops, better bread, and corn more proper for keeping. What a ſatisfaction muſt it be to a man to have made a diſcovery ſo uſeful to his fellow-creatures, whoſe chief food is the ſeveral ſorts of grain! We ſhall ſoon ſee whether habit, ſupineneſs, and ill-judged œconomy in the farmers, will not prevent them from reaping any benefit from M. Tillet's labours, who yet propoſes to them ſimple and cheap methods of attaining an end which to them ought to be of infinite conſequence. *Du Hamel's Elemens d'Agriculture, vol.* I. *pag.* 134

BUR-TREE, a name given in ſome counties to the elder-tree.

BUSHEL, a meaſure of capacity for dry things, as grain, fruits, pulſe, &c. containing four pecks, or eight gallons, or ſixteen quarts.

A buſhel, according to a ſtatute made in the twelfth year of Henry VIII. is to contain 2,178 cubic inches, or eight gallons of wheat; the gallon of wheat to weigh eight pounds troy-weight. Mr. Ray tells us, that a buſhel in Warwickſhire is equal to two ſtrikes, or two buſhels, ſtatute, or Wincheſter meaſure.

The French buſhel conſiſts of four quarters, and the quarter of four litrons, each containing thirty-ſix cubic inches. Conſequently the buſhel contains 576 French cubic inches, which, according to Mr. Greaves's calculation, is nearly equal to 615 Engliſh inches. The French buſhel therefore is to the Engliſh buſhel, as 615 is to 2,171. That is, the French buſhel contains one peck, a quart, and two cubic inches nearly. It muſt however be obſerved, that the French buſhel for oats is double that of any other grain.

BUTCHERS-BROOM, or knee-holly, the name of a plant common in woods in divers parts of England.

BUTTER, a fat unctuous ſubſtance, prepared, or rather ſeparated, frem the milk by churning it. *See the article* DAIRY.

BUTTER-BUR, or *peſtilent-wort*, the name of a weed reſembling colt's-foot in many reſpects; but the flowers are purple, and grow in a thirſe. The leaves come out after the flowers decay; and are like thoſe of colt's-foot in ſhape; but three or four times as big. It infeſts meadows and paſture grounds, where it proves a very troubleſome weed. *See the article* COLT'S FOOT.

BUTTER-FLY, the name of a numerous, and well known claſs of inſects.

M. Du Hamel has frequently noticed, and made drawings of, a ſpecies of ſmall inſects, ſome of a bright red, and others black, which are found in great numbers in the ears of wheat. He ſuſpected that they fed on a ſweetiſh juice which is in the ear whilſt green: and M. Tillet, who was immediately of opinion that they might do conſiderable damage to the grain, followed them very aſſiduouſly in all their metamorphoſes, of which he has given a full account in a memoire that gained the prize of the Academy of Bourdeaux for the year 1755.

The inhabitants of a conſiderable part of the province of Angoumois have, for thirty years paſt, ſuſtained an hitherto irreparable loſs, by an inſect which begins to devour their corn, even in the ear, before it is reaped. This ſcourge deprives them annually of their moſt promiſing crops. It appeared at firſt only in a few hamlets, but ſoon made a rapid progreſs, and has now ſpread to the lands of upwards of two hundred pariſhes. Famine and the moſt fatal epidemic diſeaſes have often taken riſe from leſs beginnings. Meſſieurs Duhamel and Tillet were deputed by the Academy of Sciences at Paris, of which they are members, to enquire into the nature of this inſect, and the means of preventing and curing that dreadful calamity occaſioned thereby. They have jointly publiſhed a ſmall treatiſe on this ſubject, from whence we ſhall extract the following remarks ſo much the more readily, as their means of prevention and cure in this particular caſe may be equally applicable to the injuries done to corn by inſects in general.

This inſect is moſt generally known as a butterfly, very much like the moth which preys upon woollen cloths,

or

or the falſe moth, which is found in great quantities in the granaries of all countries, and which feeds on corn. M. de Reaumur, whoſe accurate inquiries into nature nothing could eſcape, has minutely deſcribed both theſe inſects.

The butterflies which proceed from the wheat caterpillar are often ſmaller than the falſe moth. Some of them are, however, larger, and longer ſhaped: but, that excepted, they are much like them: they are likewiſe of the claſs of four-winged phalenæ or night butterflies; their wings are long in proportion to their breadth, which is almoſt equal at the upper and the lower end. The colour of the upper wings varies; being ſometimes of a light, and ſometimes of a darkiſh grey brown, but always ſhining when expoſed to the ſun. The poſition of theſe wings, of which the edges are thoſe ſet with long hairs, is horizontal when the inſect firſt ſettles after having flown; but ſoon after thoſe edges incline downward. Its head (Plate V. Fig. 24, 25, 26.) is furniſhed with two antennæ (Fig. 27.) the joints of which, nicely fitted into each other, leſſen gradually up to the point. Its eyes are almoſt as large as thoſe of the falſe moth. Between the antennæ are two beards, (Fig. 28.) which proceed from the lower part of the head, and riſe up above it; and likewiſe between the antennæ is a tuft of hairs, which turn up backward.

Theſe inſects do not take any food while they are in the ſtate of butterflies, as will be proved by ſeveral experiments; nor do, or indeed can they, prey upon and deſtroy corn during that time, as is the general, but miſtaken opinion in Angoumois; for they have not even organs capable of doing it the leaſt injury. Their only function then is to procreate their ſpecies.

The males of theſe butterflies ſeem, in general, to be larger than the females: but they cannot well be diſtinguiſhed with certainty, unleſs they are ſeen coupled together, which, according to the very nice and careful obſervations of Meſſ. Duhamel and Tillet, never is but in the night-time, or in a dark place. Their copulation then is like that of the ſilk-worm butterfly: the body of the male and that of the female then form one ſtrait line; their heads are turned different ways; the ends of their wings reſt upon each other; and their conjunction laſts ſeveral hours. The abovementioned gentlemen, with many other witneſſes, ſaw great numbers of them in this ſituation, both upon heaps of corn in granaries, and upon ears of corn in the field. They catched two of them in the act of copulation, and put them into a glaſs covered over, where they then ſeparated, but were found joined together again the next day, in the evening.

As ſoon as the female is impregnated, ſhe lays her eggs in great numbers. Meſſieurs Duhamel and Tillet put a male and female, coupled, into a glaſs veſſel, and, watching them carefully, ſaw the female, ſoon after her ſeparation from the male, depoſit her eggs, ſometimes on one ſpot and then on another, in heaps of 60, 80, or 90 together. Theſe eggs are ſquirted out, as it were, commonly by three, four, or half a dozen, and ſometimes thirty, at once; and at each ſquirt of this kind the female changes her ſituation. Thoſe which were incloſed in glaſſes caſt ſome of their eggs upon a few grains of corn depoſited at the bottom of thoſe glaſſes, and, finding themſelves cramped there, laid others on the ſides of the veſſel. Theſe eggs are accompanied with a viſcous matter, which makes them ſtick to the places they are laid in; and this coheſion ſoon becomes very ſtrong.

Theſe eggs, as may eaſily be imagined from the ſize of the mother and the great number which ſhe lays, are ſo extremely ſmall that one of them would drop through a hole made in a bit of paper with the point of the fineſt needle. When examined by a microſcope, they look, as in Fig. 4, not unlike the nymphs commonly called ants eggs. They are ſtreaked length-wiſe, and appear rough or curdled. When firſt laid, they are white; and afterwards they become red, as if tinged with carmine; owing to the colour of the caterpillar within the egg, of which the ſhell is very thin and tranſparent, as is evident after the caterpillar has left it.

By means of the thinneſs and tranſparency of this covering, the caterpillar may be ſeen within the egg, as at *b*, Fig. 5. At firſt, it is bent, as in Fig. 6: ſome time after, it wriggles itſelf into the ſituation repreſented in Fig. 7; and then makes a hole through the end of the egg, and comes out there, as in Fig. 8. This opening remains at the end of the empty eggs, as at *c*, in Fig. 5.

It is with great difficulty that the caterpillar gets its two legs out of the egg; but after it has extricated four or ſix of its legs, it ſoon draws out the reſt of its body. At its firſt iſſuing from the egg, this caterpillar looks like a bit of hair about a quarter or a fifth part of an inch long.

Theſe catterpillars generally come out of their eggs on the ſixth or ſeventh day after they have been laid. Some ſay they have ſeen them hatch at the end of four days. The temperature of the air will undoubtedly influence this variation. They are red, as was ſaid before, whilſt in the egg; but that colour goes off by degrees after they are hatched, and they ſoon become almoſt white.

The female butterflies which are upon the ears of corn in a field, endeavour to place themſelves in ſuch manner as to lay their eggs cloſe to the place where the grain is faſtened to the ſtalk. Fig. 1. repreſents ſome of them, at *a*, in the attitude of thus laying; in which caſe their eggs are depoſited near the bottom of the grains, toward the ſtalk: but it often happens that, in their hurry to lay, they ſcatter their eggs in other places, as repreſented upon the huſks in Fig. 2 and 3.

As ſoon as the caterpillars are hatched, they ſet about making their way into the grain, in order to feed upon its flour. If the eggs have been laid in the granary, after harveſt, and upon the grains themſelves, they generally creep into the furrow *a* of the wheat (Fig. 9. and 10), and there weave a ſlight web *b b*. They then tear a hole in the ſkin or rind, range around them the particles of the bran thus ſeparated, and wriggle themſelves into the mealy ſubſtance which is to be their food. The hole through which the caterpillar entered can then no longer be perceived, but by a little heap of bran which lies upon it, as in Fig. 11. This ſmall quantity of pulveriſed bran, which is a ſure ſign that a young caterpillar has got into the grain, may eaſily eſcape the notice of thoſe who have not obſerved it before; but when once known, it is eaſily diſtinguiſhed.

When the eggs are hatched upon the ears, in the field, the young caterpillars ſoon find means to glide in between the chaff and the grain, and in that ſituation they pierce the latter, as was ſaid before, generally in the furrow, but ſometimes at the pointed end, which is a little hairy.

To ſet this in a yet clear lighter, it is to be obſerved, that, in moſt kinds of wheat, three grains of corn adhere, or are faſtened, at the ſame height, to the ſpike or ſtalk which traverſes the ear, as at *b b b*, Fig. 1. in ſuch manner as to form a ſort of triangle, or flower-de-luce. Each grain is covered with three concave coats or huſks, the ſmalleſt and thickeſt of which is repreſented by Fig. 2 and 3: their inner huſk is covered by a broader, but thinner; and this grain is covered by a ſtill larger, from which ariſes the beard, when there is one. Over all theſe there frequently is a fourth tegument, or very thin membrane, more or leſs wide. All theſe huſks lap over each other like the ſcales of a fiſh, and invelop the grain. The end *e* (Fig. 9.) is uppermoſt, and the end *f* reſts upon its ſupporter. The germ is at the end *f*, and the extremity *e* is covered with a hairy down.

The young caterpiller finds means to creep under all theſe ſcale-like coverings, and to get at the grain, which, after having wove a ſlight web of only a few fine threads, either to cover itſelf, or to hold by, it attacks, ſometimes at the upper end *e* (Fig. 9), which is very ſoft in green corn; and ſometimes, if it has crept in at the lower end, it lodges in the longitudinal furrow of the corn, and there begins to mine in the manner before related.

As the huſks of barley are harder, and ſtick much cloſer to the grain, than thoſe of wheat, it is almoſt always at the point *d* (Fig. 12.) that theſe caterpillars ſlip into that corn, by means of a ſmall opening generally perceptible in that part.

To conceive how theſe ſmall caterpillars, which are hardly able to pierce the rind or bran of wheat, can glide into barley by means of the opening before mentioned, it is neceſſary to conſider the organiſation of this grain. It is formed of two lobes *c c*, Fig. 12. which are partly ſeparated by a furrow in its middle, and partly covered by a tegument *a a*, which ſits exactly cloſe and adheres ſtrongly to the lobes *c c*, and terminates in a long awn or beard *b*, of which only part is repreſented in this drawing. The two lobes *c c* are again covered with their proper tegument, which ends in two ſmall appendices at *d*. Here generally is a chaſm or opening, through which the caterpiller penetrates to the mealy ſubſtance.

To trace this caterpillar in its further progreſs after it had crept in at this opening, and conſequently diſappeared, Meſſieurs Duhamel and Tillet tore off the appendices *d*, Fig. 13, and found, that after having wove a ſlender web, it had immediately begun to attack the lobes of the grain of barley, as was evident from the bran around it. After it had made its way entirely into the grain, and was buried there, they ſaw nothing but the little heap of bran it had thrown up, over the hole through which it entered.

Notwithſtanding the induſtry of this inſect, it ſeems highly probable that the young one's meet with great difficulties in their attempts to get into the grain; ſince very many of them die before they can effect a lodgment in the mealy ſubſtance. This number is ſo great, that it might induce one to wonder how ſuch quantities of corn can be deſtroyed by theſe caterpillars, if one did not conſider the vaſt fecundity of the female butterflies. But the ſequel of this account will ſhew, that if prodigious numbers of them did not periſh, it would hardly be poſſible to ſave a ſingle grain of any kind of corn.

The people of Angoumois were ſtrongly of opinion, that the miſchief occaſioned by this inſect was peculiar to the corn of their country, and that what was brought to them from other places always eſcaped unhurt. To clear up this point, Meſſ. Duhamel and Tillet put into different glaſſes wheat of the growth of other provinces, and with the grains, in each glaſs, ſome of theſe butterflies actually coupled. They ſoon ſaw the female lay her eggs upon theſe grains, and afterwards beheld the caterpillars hatch, and make their way into the grains. Their farther obſervations proved, that the principal cauſe of the ſpreading of this evil is, that the inſect itſelf, which multiplies exceedingly, is conveyed to other parts with the corn in which it is incloſed.

The caterpillar incloſed in a grain of corn preys upon the mealy ſubſtance of that grain, till it has eaten it all; by which time the inſect has attained its full growth. Whenever a grain was opened (Fig. 19.) in which the caterpillar was not full grown, a deal of flour yet remained: but when this inſect was full grown, there remained only the ſkin, or bran, ſo deſtitute of flour, as not even to diſcolour clear water. Hogs, though very greedy creatures, and fond of bran, would not touch theſe hulls when given to them unmixed; but they eat them readily enough when mixed with other food.

M. de Reaumur ſuſpects that when theſe caterpillars have conſumed all the flour, they eat the excrements which they had voided whilſt young. At leaſt it is certain that, upon opening ſeveral grains in which the inſect was young, a number of ſmall white pellets, like eggs, was found near the caterpillar; and a half-grown caterpillar being taken out of a grain, and laid upon a piece of glaſs at the focus of a microſcope, it was ſeen to void a quantity of excrements, very white, ſmooth, and oval; and when the caterpillars were ready to be metamorphoſed in the ſpring, there remained only a very ſmall portion of dark brown excrements, quite different from the white that were obſerved at firſt.

The length of the corn-caterpillar, when full grown, is very little more than the twelfth part of an inch; and its thickneſs is, at moſt, equal to half the circumference of the grain that contains it: its body is ſmooth and entirely white: it is thickeſt towards the head, in which one may perceive its mouth, two large eyes, and two kinds of horns: the head is a little browner than the reſt of the body. This caterpillar has ſixteen legs, of which the eight intermediate and membranous are only ſmall prominencies, ſo minute as not to be diſtinguiſhed even with the help of a microſcope, unleſs the inſect be laid upon its ſide.

Our authors make here the following digreſſion, to ſhew the difference between this inſect (Fig. 23.) and the falſe moth (Fig. 31.); it being the more important to diſtinguiſh them, as they are very much alike in many reſpects, and often blended together in the ſame granaries.

The falſe moth proceeds from a ſmall caterpillar, the body of which is ſmooth and whitiſh. It has ſixteen legs, does not lodge in the grains of corn, but contrives to faſten ſeveral of them together with a web which it ſpins, and with which it makes itſelf a dwelling-place like that of common caterpillars. This dwelling-place, or ſheath, in which the caterpillar of the falſe moth uſually abides, is generally in the middle of the little heap of grains which it has collected for its food, as in

Fig.

Fig. 30: but, which diſtinguiſhes it from the caterpillar of the true moth, it can quit this ſheath at any time, to eat the grains around it, one after another. It generally attacks ſeveral grains at once, and always without order, eating ſometimes of one, and ſometimes of another, ſo that ſeveral are gnawn when not one is wholly conſumed. When theſe inſects are very numerous in a granary, all the grains upon the ſurface of the corn are linked together by a web, ſo as to form a cruſt which is ſometimes three inches thick. This caterpillar turns into a chryſalis, or aurelia, in a grain which it has hollowed, or in the ſheath of its web, and iſſues from thence, in the month of June, in the form of a butterfly. When a heap of corn is ſtirred in which there are many caterpillars of the ſpecies of this falſe-moth, thoſe inſects crawl up the walls: but they ſoon return to the heap, and, by the very next day, cover it all over with a new web.

The inſect which deſolates many parts of Angoumois is more ſparing of the mealy ſubſtance of the corn, than the caterpillar of the falſe-moth; for the former ſeldom conſumes more than the contents of a ſingle grain. Nothing is more uncommon than for it to paſs from one grain to another, even though it be immediately contiguous. It eats the flour in ſuch manner that the ſkin or rind of the grain, which is entirely emptied, looks whole and ſound: but the leaſt preſſure then eaſily reduces it to powder; and it riſes up to the ſurface of water more or leſs quickly, according as the inſect has left in it more or leſs flour.

As heat haſtens the metamorphoſis of the inſect, it is not unuſual to find, in very hot weather, ſome of theſe caterpillars transformed into aureliæ, before they have conſumed the groſs excrements before-mentioned, or even eaten all the mealy ſubſtance of the grain. In this caſe, the aureliæ are very ſmall, and produce only ſmall butterflies. The ſame happens to other inſects of this kind. Silk-worms eat but little when they are ſickly, and, if that ſickneſs continues, they are metamorphoſed ſooner than others which are healthy; but then their cocons always are ſmall. If a field caterpillar be ſhut up in a box before it has attained its full growth, it will, after having faſted ſome days, be converted into a ſmall aureliæ, from it will iſſue a butterfly ſmaller than others of the ſame ſpecies. In like manner, when one ſees among the corn caterpillars ſome larger than others, it may reaſonably be preſumed that this difference proceeds from their having been a greater quantity of flour in the grains on which they fed, than in thoſe which were the nouriſhment of ſmaller flies; or from their having been of a ſtronger conſtitution. It likewiſe appears that ſome of theſe caterpillars are ſo much more voracious than others, that the flour of one grain is not ſufficient for them. M. Duhamel put ſeveral of them into a box of flour: they throve there, and ſeemed to grow larger than in their common way of feeding in the grain.

In general, they are matamorphoſed much ſooner in ſummer and when the air is warm, than in winter, or in cold weather. It may likewiſe be obſerved, that the mealy ſubſtance of a grain is more completely conſumed when the metamorphoſis is ſlow, than when the contrary happens.

The ſagacity of M. de Réaumur was requiſite to diſcover a ſingular circumſtance relative to the working of this inſect, and of which Meſſ. Duhamel and Tillet have been witneſſes. The caterpillar, exactly incloſed in its grain, foreſees, or acts as if it knew, that, in its future ſtate of butterfly, it will be deprived of the organs neceſſary to pierce through the rind of bran which forms its priſon. However, whether it has or has not that foreſight, the fact is, that the caterpillar, before it is changed into an aureliæ, makes in this covering of bran a ſmall trap *a* (Fig. 21.) which remains ſhut. Meſſrs. Duhamel and Tillet could not eaſily diſcover it at firſt; but after ſome ſearch, a little ſpot whiter than the reſt, about as big as the head of a ſmall pin, and ſomewhat prominent, ſhewed them where it was. They then, upon lifting up this trap (Fig. 22.) with the point of a fine needle, could ſee the chryſalis in the inſide of the grain, and could alſo, ſometimes, cloſe the trap again ſo exactly, as not to leave the leaſt appearance of a hole.

When the caterpillar has attained its full growth, and formed its trap, or outlet, it weaves a cocon, and is afterwards metamorphoſed, within the grain, into an aureliæ (Fig. 20.) which ſeems at firſt to be divided by ringlets (Fig. 14.); but when the butterfly is formed within the aureliæ, its wings may be diſcerned through the membranes which cover it, as in Fig. 15, 16, 17, 18. The above-mentioned accurate obſervers opened ſome of theſe aureliæ in an advanced ſtate, and took out of each of them a butterfly greatly rumpled and benumbed. When one of theſe caterpillars firſt iſſues out of an egg, and when a full grown one is taken out of a grain of corn, the body of each, then ſeemingly more at eaſe, dilates, ſo that one can hardly conceive how it could be contained in ſo ſmall a ſpace as that from whence it came. The caſe is different when one opens a grain in which there is an aureliæ; for it is eaſily ſeen that this occupies little more than half of the inner capacity of the grain which incloſes it, and that the caterpillar, in forming a cocon, has divided the grain into two ſpaces or cells, in the largeſt of which, being ſomewhat more than half, the aureliæ is lodged, whilſt one ſees in the other nothing but its excrements. The aureliæ are therefore ſmall in compariſon to the caterpillars that were metamorphoſed into them. Nor is it leſs ſurpriſing how a butterfly juſt come out of the aureliæ could be contained within that covering.

The butterfly, being entirely formed in the aureliæ, breaks the ſkin of it at the end, opens with its head the little trap which the caterpillar had made on the outſide of the grain, and comes out at the little hole which was covered and ſhut by that trap. The mealy ſubſtance of the grain has, by that time, been ſo far conſumed, and the outſide huſk or bran rendered thereby ſo light, that the butterfly, after having diſintangled its wings, takes its flight, and ſometimes carries away the empty hull. As ſoon as the butterflies are out of the grains which contained them, they couple, and the females lay their eggs in the manner before related. Such is the circle of their life.

This inſect, like all others of the ſame ſpecies, remains, as was ſaid before, a longer or ſhorter time in its different ſtates, according as the temperature of the air is more or leſs favourable to its ſeveral changes. It is known that an aureliæ of a caterpillar, which generally produces a butterfly in eight days, will continue three months in the ſtate of an aureliæ, if it be put into an ice-houſe, and that the butterfly does not, in that caſe, come

come out, till after it has been removed into a much warmer air. For this reaſon one cannot fix preciſely the time within which the caterpillars are transformed into aureliæ, nor how long they remain in this ſtate: it can only be ſaid, that they come out of their eggs very ſoon when the air is warm, and that they ſometimes continue long in the ſtate of caterpillars, as well as in that of aureliæ, if the weather be cold: to which may be added, that both caterpillars and aureliæ, of different ſizes, are ſeen in the field in warm weather; that butterflies are ſeen to iſſue out of corn from harveſt till the end of September; and that caterpillars of various ſizes may be found in the infected grains, during the whole winter.

"In the middle of May 1761," continue Meſſieurs Duhamel and Tillet in their account of this inſect, "when we arrived at la Rochefoucault, there were many caterpillars in the corn, very few aureliæ, and not many butterflies. The weather was then very dry, and the nights were cold. On the 21ſt, the wind changed to the weſt; and in a few days after it began to rain, and continued ſo to do till the end of the month. During this time the thermometer was at from 13 to 14 degrees of Reaumur, or from 56 to 58 of Farenheit.

"In the beginning of June, we found in the grains of corn many more aureliæ than caterpillars; and on the 5th of that month, the air being then become pretty warm, we ſaw numbers of butterflies. By the 15th, they were increaſed ſo prodigiouſly in the cloſets where we made our experiments, that they perfectly darkened the day, and flew into our mouths if we opened them. We could then find but very few caterpillars, except in the corn which had been laid in cool places. We believe that the duration of the life of the butterflies is, in general, a fortnight or three weeks; though ſome of them have lived a month in our glaſs veſſels. The ſequel will ſhew that the whole circle of the life of this inſect may be completed in leſs than fifty days, when the air is warm.

"The coming out of the butterflies is generally denoted by a great heat in the heaps of corn, or in the ſheaves, according as the grain is laid up in one or other. It was ſuch as to make the liquor in M. de Réaumur's thermometer riſe to 25 and 30 degrees (from 62 to 71 of Farenheit) when the outer air was at 15, (35 and a half of Farenheit). This heat certainly accelerates the hatching of the inſects; for prodigious multitudes of butterflies iſſue out of the heated corn in a few days after the ferment has taken place.

"The coolneſs of autumn interrupts their propagation; and no more butterflies appear from that time, till the warmth of ſpring begins to be felt. But, may not the heat, which favours the multiplication of theſe inſects, be produced by the creatures themſelves when aſſembled in vaſt numbers? This is very poſſible: for it is well known that there is a conſiderable warmth in well ſtocked bee-hives; and that corn greatly infeſted with weevils or moths, is alſo very hot. We ſhall hereafter have occaſion to obſerve that no ſenſible heat is perceived in heaps of grain in which there are but few caterpillars, and that the heat abates after moſt of the caterpillars have been changed into butterflies. It ſometimes happens that, through ſome cauſe or other, the heat goes off ſoon, and at other times it laſts three weeks or even a month. Perhaps too this great heat of corn full of caterpillars may proceed from the moiſture which thoſe inſects occaſion, and from thence may ariſe a fermentation capable of hatching the eggs, of making the caterpillars grow, of haſtening their transformations, and of bringing forth the butterflies, at the ſame time that it damages the corn, which thereby contracts a bad ſmell. It is certain, that when the harveſt is wet, and warm rains fall at that time, the corn heats very ſoon, and then theſe inſects make an extremely rapid progreſs. The heat which the corn contracts is doubtleſs very favourable to that progreſs, and the inſects certainly may then attack the grains ſoftened by the moiſture, more eaſily than they can thoſe which are hardened by drought. Accordingly, in 1760, a year in which the heat was great, and the air very dry, the corn in Anjou kept cool ſo long that many of the inhabitants of that province thought there would be but few inſects, and that the great heat of the ſun had killed moſt of the caterpillars. They flatter themſelves with the ſame hopes whenever theſe inſects do not appear in great numbers quite ſo ſoon as uſual, and imagine that few or none of them will come afterwards: but in that very year, which they thought ſo fatal to inſects, we ſaw butterflies come out of the ears of corn while they were in the reapers hands; we ſaw ſtill more fly about the ſheaves laid up in barns, and an inexpreſſible multitude upon the ſurface of corn depoſited in granaries, though neither of theſe grew very perceptibly till about the middle of September. In 1761, the corn was ſo much heated on the 8th of September, that though the outward air was of the ſame temperature as that in the vaults of the obſervatory at Paris, Réaumur's thermometer placed in one of thoſe heaps roſe to 53 degrees, (131 of Farenheit's). The great heats of the ſummer had therefore only deferred the evil, and perhaps leſſened it a little. But this dreadful ſcourge returns every year. Theſe caterpillars, incloſed in their grain of corn, and ſheltered in barns or granaries, are ſcreened from the viciſſitudes and rigour of the air which deſtroy other inſects that are expoſed to them.

"Let us now review our inſect in all the ſeaſons of the year, in order to try to find under what circumſtances it may be attacked with moſt advantage.

"At harveſt-time, we ſaw butterflies come out of ſome grains, which were already empty and entirely conſumed, before they were reaped. Doubtleſs theſe firſt butterflies couple and lay their eggs upon the other unreaped ears, and probably part of thoſe eggs are deſtroyed by the action of the flail, when the corn is threſhed and cleanſed ſoon after its being cut: but as the caterpillars are hatched very ſpeedily in hot weather, and many of them can, as in fact we ſaw them, enter into the corn that is reaping, and ſhelter themſelves there; they will do all their miſchief, if ſpeedy care be not taken to ſtifle them, as we ſhall hereafter obſerve.

"The reaped corn is laid up in ſheaves in barns, till the huſbandman can find time to threſh it, which is ſometimes ſooner, and ſometimes later. The corn thus piled up, heats; and the transformations of the inſects incloſed in it are then the ſooner effected. When any of theſe piles of ſheaves were ſtirred in our preſence, we ſaw butterflies come out of them, and the grains from which they iſſued were empty of flour, and abſolutely ſpoiled. The moment theſe butterflies are out of their priſon, they couple, and lay their eggs upon the ears

which

which they find in the barn. Part of theſe eggs, and of the young caterpillars, might certainly be deſtroyed by the flail and winnow, as we ſaid before, if they were uſed ſpeedily.

" Many peaſants in the country we are ſpeaking of make all the haſte they can to threſh their little crops, which they generally do upon a very dirty floor made in a hurry in the open air. They winnow and cleanſe their corn as ſoon as it has been threſhed; and the empty grains are then partly ſeparated from thoſe that are full, by the wind, which carries the lighteſt away with the chaff.

" As the dirtineſs of the floor on which the ſheaves are threſhed fouls the grains of corn, theſe people waſh them, and thereby take off ſuch of the remaining light grains as ſwim upon the water. They likewiſe ſeparate the grains of which the caterpillars have eaten ſo much of the mealy ſubſtance as to render them ſpecifically lighter than the water: but the grains of which the caterpillars have not eaten much of the flour, ſink to the bottom with ſound ones; and the caterpillars devour thoſe infected grains after they are ſoftened by the water, much ſooner than thoſe which are thoroughly dry.

" Moſt of theſe peaſants, knowing the ill fate that will attend their corn, ſell it as ſoon as poſſible to dealers, who carry it into the neighbouring provinces, and with it the contagion. This is the real cauſe which ſpreads the evil. Others have their corn ground immediately after harveſt; and this is the beſt method they can take, though not without its inconveniencies: for, in the firſt place, there are not mills enough in the country to grind immediately the whole produce of the crop; ſecondly, the meal of corn gathered in a wet harveſt will not keep long; and laſtly, though the friction of the mill-ſtones undoubtedly deſtroys almoſt all the inſects, it is not certain but that ſome of them may eſcape; and in that caſe they will thrive, and go through their ſeveral metamorphoſes, firſt into aureliæ and afterwards into butterflies, in the flour, as we have experienced in the manner before related.

" Several of the inhabitants of the country in queſtion lay their corn up in granaries, in order therewith to pay their rent, which, in general, is not due till the beginning of October. From theſe heaps of reſerved corn iſſue multitudes of butterflies, which, as we have obſerved, couple and lay upon that corn an immenſe quantity of eggs, from whence proceed caterpillars which get into the grains, and devour their inſide during the whole winter.

" It is highly probable that, in mild and moiſt autumns, ſome of the firſt hatched caterpillars may be changed into butterflies early enough to produce a ſecond generation before winter; nor will this ſeem ſurpriſing to thoſe who know how rapidly warm weather makes theſe inſects go through all their metamorphoſes. But, independent of this, it is certain that butterflies are continually ſeen to come out of all the heaps of wheat, barley, and rye, in Anjou, during the whole ſummer, and till the autumn begins to grow cold; that numbers of live caterpillars are found in the grains during the winter; that many aureliæ are found in them towards the end of May; and that prodigious multitudes of butterflies iſſue from them as ſoon as the weather begins to be hot, that is to ſay, towards the middle of June.

" Thus we ſee that there are, in a manner, two flights of butterflies; one which appears from harveſt time till the weather grows cold in September, and the other which appears in June, and laſts till harveſt. The former, in our opinion, proceed partly from granaries in which corn of the preceding year has been laid up with young caterpillars in it, and partly from the eggs firſt laid upon the ears, towards the end of May, or upon the new reaped corn; ſo that the ſecond flight begins juſt as the firſt flight ends.

" A circumſtance well worth obſerving, and which will be more particularly noticed hereafter, is that moſt of the butterflies of the ſummer flight remain in the granaries, faſt clung to the threſhed corn, upon which we have ſeen them couple and lay their eggs. It looks as if theſe butterflies knew that there then no longer is in the fields any corn fit to feed their poſterity. On the contrary, thoſe of the ſpring flight endeavour to get out of the granaries, and do in fact get out in vaſt numbers, through the windows, to ſpread in the fields, and lay their eggs upon the yet green corn.

That this is really the caſe, and that theſe inſects are of the ſpecies called *phalenæ*, appeared evidently from ſeveral very accurate obſervations, made by Meſſrs. Duhamel and Tillet, and of which it may be ſufficient to mention here only the following.

In June 1761, they went, at different hours of the day, into granaries where there were heaps of corn infected with theſe inſects. While the day laſted, they perceived a multitude of butterflies which ſtirred a little upon thoſe heaps, but did not quit them. When they returned into the ſame granaries a little after ſun-ſet, they ſaw thoſe butterflies riſe from the corn, and fly to the walls, where they ſettled for a while; after which they took their flight in vaſt numbers, through the windows, and went off with ſuch rapidity that they ſoon got out of ſight. If Meſſrs. Duhamel and Tillet went back into theſe granaries at ten or eleven o'clock at night, they no longer ſaw ſo great a number of butterflies, and thoſe that did remain ſeemed to be leſs agitated.

To be ſtill more perfectly acquainted with ſome circumſtances of the life of this inſect, they put different ſorts of corn into ſmall cloſets, in September 1760, after having paſted white paper all over the walls and ceiling. In the beginning of June 1761, theſe cloſets ſwarmed with butterflies, which ſeemed to be pretty quiet during the day, and were ſeen to be greatly agitated towards the ſetting of the ſun: but they could not get out of the cloſets, becauſe the windows were cloſely ſhut. On the 9th of June, towards eight o'clock in the evening, one of the cloſet doors being opened, a prodigious number of butterflies immediately iſſued out, and, with ſurprizing ſwiftneſs, traverſed an oppoſite granary, without making the leaſt ſtop, though ſeveral heaps of wheat lay in it. They bent their courſe directly to an open window of the granary, at ſome diſtance from the cloſets, and inſtantly haſtened out. Several people, who were preſent, followed them with their eyes, till the ridge of a barn near forty feet off, and the decline of the day, prevented their ſeeing them any further. Our obſervers returned to the ſame cloſet at about ten o'clock at night, and then found the remaining butterflies very quiet, ſcarce one of them attempting to fly out.

Theſe obſervations prove ſufficiently that this ſpecies of butterflies is nocturnal, and that thoſe of the June

flight

flight have a different inſtinct from thoſe which do not appear till after harveſt. Theſe laſt remain upon the corn in the granary, and there couple and lay their eggs, from whence proceed caterpillars which penetrate into the grains as ſoon as they are hatched. The June caterpillars, on the contrary, act as if they knew that the bloſſoming of the corn is paſt, and that its ears are fitted to ſupply their poſterity with their neceſſary food. They ſeldom leave the granary before ſun-ſet, unleſs dark clouds chance to beguile them earlier, in which caſe numbers of them become the prey of ſwallows and martins, which fly about the windows.

As theſe little inſects fly very ſwiftly, and riſe to ſuch a height that the eye cannot follow them long, eſpecially when the duſk of the evening begins to come on Meſſrs. Duhamel and Tillet were obliged to try ſeveral methods before they could be certain what became of them. The caterpillars which they found in the grains of ſtanding corn made them conclude that the butterflies, when out of the granary, flew directly unto the green corn, and laid their eggs upon its yet tender ears: but none of the country people, of whom they inquired, had ever obſerved them in the fields, or could give any ſatisfactory account of them. Another well atteſted circumſtance, which ſtrengthened their conjecture, was their being aſſured by perſons of undoubted credit, that the corn which grows neareſt to villages, farm-houſes, barns, or buildings uſed for granaries, is always much more damaged by inſects than that which grows at a diſtance from any habitation. Their own obſervations confirmed this fact; and their experiments, dictated by reaſon, ſoon proved that they had conjectured right.

Deſirous to know what was become of the ſwarms of butterflies which they had ſeen go out of the granaries in June 1761, they ſearched all the neighbouring fields of every kind of corn, and beat even the ſurrounding hedges, at all hours of the day, to no ſort of purpoſe: not a butterfly could they find, excepting a few dead and dried ones intangled in ſpiders webs along the outſide of the corn. This very circumſtance led them to the diſcovery they were in queſt of: for, rightly reflecting that theſe inſects, which neither they nor any other perſons had been able to find in the fields in the day time, muſt certainly be of the *phalenæ* or nocturnal kind; they, without farther delay, ſet out with a candle and lanthorn, repaired to one of the corn fields which they had viſited in the afternoon, and, in the night between the 5th and 6th of June, ſoon deſcried a great number of the very butterflies they were ſeeking for, upon the beards of the ears of wheat. They returned to the ſame ſpot early the next morning, and could not then find a ſingle one.

From that time they ſaw and ſhewed to whoever choſe to ſee them, a great number of theſe butterflies upon the ſtanding wheat and barley. Some were upon the beards, and others had made their way to the point of the grain. Scarce an evening paſſed without their ſeeing ſome of them coupled. Though every circumſtance concurred to prove, and indeed left no room to doubt, that theſe butterflies were the ſame as thoſe which infeſted the corn in granaries; yet, to be thoroughly convinced, and to convince others, in this reſpect, they took ſome of them from off the ears of corn in the field, examined them with a microſcope, and found them to be of the very ſame ſpecies. A farther demonſtration of this reſulted from the following incidents. M. de Taponnat, one of their friends in Angoumois, had, in a ſmall granary, ſeveral heaps of wheat differently prepared, which he kept by way of experiment. Meſſrs. Duhamel and Tillet obſerving numbers of caterpillars in two of thoſe heaps, adviſed him to put that corn into an oven properly heated, in order to prevent the diſperſion of the butterflies, which they knew would otherwiſe infallibly proceed from thence: but this was neglected. On the 21ſt of June, about ſeven o'clock in the evening, they viſited this little granary, and found upon the corn a multitude of butterflies in great agitation, and of which a conſiderable number ſoon flew out at the windows. They took leave of M. de Taponnat, aſſuring him that this flight of inſects would ſoon light upon his ſtanding corn. When they were gone, M. de Taponnat had the curioſity to ſtep out, to ſee whether any great quantity of butterflies ſtill continued to iſſue from his granary; which he could eaſily do, as the window was very low. He was amazed at the numbers he ſaw fly out at that one window; being, as nearly as he could compute, about fifty in a minute. He obſerved, that they directed their flight towards a field of wheat not far off, and thereupon went thither with five or ſix other perſons, all of whom ſaw them arrive in ſwarms, proceeding chiefly from the granary. They ſaw many of them light upon the ears, and on their running a cane gently over the awns, beheld them riſe by dozens at a time. M. de Taponnat was ſo ſtruck with this ſight, that he ordered the window of his granary to be ſhut the next day, and his corn to be put into an oven properly heated, as ſoon as poſſible.

A clergyman in the neighbourhood, who had a little barley infeſted with theſe inſects, could not be perſuaded to do the ſame, though his whole quantity was but a few buſhels. The conſequence was, that a multitude of butterflies were ſoon ſeen to proceed from the window of his granary, and ſpread ſo thick over an adjacent field of barley, that not an ear could be found without ſeveral of them upon it.

Theſe facts confirm all the former remarks of our accurate inquirers, who, after obſerving that the fitteſt time to find theſe butterflies upon the ears of ſtanding corn, is about half an hour after ſun-ſet, continue thus.

"On the 10th of June about eight o'clock in the evening, we viſited the fields around la Rochefoucault, and then perceived only a few butterflies upon the ears of the corn: they were greatly agitated; and we ſoon after ſaw numbers of the ſame ſpecies arrive on all ſides, but chiefly from certain mills on the banks of the river. Thoſe that were upon the corn flew away as ſoon as we approached them with a light. This was probably the time of their arrival. Towards nine o'clock we renewed our ſearch, and ſaw many of them clung to the ears, either actually coupled, or ſeeking to couple. The light did not affright them then, and we had time enough to examine them with a microſcope. We found fewer of them towards midnight, and could not ſee any early the next morning. It is not to be ſuppoſed that the diſperſion of theſe butterflies happens always regularly at the hours before-mentioned; for we have obſerved ſeveral variations, which depend on the warmth of the air; and they commonly ſettle upon the corn earlier when the ſun is overcaſt with clouds juſt before its ſetting.

"As we have not ever met with theſe butterflies in the

the day time, it may be aſked, where they then retire to? This queſtion deſerves an anſwer. We have ſearched for them in vain in hedges and among the blades of corn. Light certainly incommodes them: for when we expoſed to the ſun veſſels in which ſome of them were incloſed, they hid themſelves in the ſhade formed by creaſes of the paper at the bottom of thoſe veſſels, in ſuch manner that we were ſometimes puzzled to find them again. One day that the ſun ſhone very bright, we took two chriſtal cups, into one of which we put a few grains of wheat with ſome butterflies, then covered it with paper, and placed it upon its bottom, in a garden expoſed to the ſun. We put ſome butterflies into the other, but not any corn, and placed it cloſe to the former, with its bottom uppermoſt, that the butterflies might receive the full heat of the ſun: and laſtly, we ſet one of M. de Reaumur's thermometers upon the ground, juſt by theſe cups. When the liquor had riſen to from 45 to 50 degrees, (from 112 to 124 of Farenheit's) we ſaw that all the butterflies in the cup where there was not any corn, were dead: in the other, only ſome were dead; becauſe moſt of them had found a ſhady ſhelter, either by making their way into the grains, or by hiding themſelves under the paper cover. We knew before, that theſe butterflies are greatly agitated, and flutter very much when they are expoſed to the ſun; but we could not tell whether that proceeded from pleaſure or pain. The doubt is now removed; and we are of opinion that they retire to a cool or ſhady place during the day time, and that their ſmallneſs prevents our finding where they are hidden, which may perhaps be in woods or thickets, in crevices in the barks of trees, or in the earth."

That the caterpillars which produce firſt aureliæ, and then theſe butterflies, can, and frequently do, live under-ground, that they can paſs the winter there incloſed in the grain with which they are ſown, and even undergo their ſeveral metamorphoſes in the earth, ſo as to ariſe from thence in the form of butterflies in the ſpring, has been demonſtrated by the following experiments.

In May, 1761, Meſſieurs Duhamel and Tillet planted, in a garden-pot, corn in which they knew there were caterpillars. They buried it an inch deep, watered it carefully, and ſaw that, notwithſtanding plentiful rains had fallen upon it, thoſe caterpillars changed into aureliæ juſt as if they had been in a granary. Theſe aureliæ produced butterflies, which, weak as they were when firſt hatched, ſoon made their way out of the ground.

To be the more certain of their power, with reſpect to this laſt article, the ſame gentlemen put ſome thouroughly dry, and well pulveriſed earth into a glaſs veſſel, then laid upon that earth a layer of corn in which they knew there were aureliæ, and covered this with equally will dried and pulveriſed earth, at leaſt half an inch deep; after which they tied a paper over the veſſel, to keep in the butterflies, in caſe they ſhould pierce through the upper mould. In effect, they did pierce through it, coupled, and laid ſuch quantities of eggs as covered its whole ſurface.

To ſee whether theſe inſects would riſe as eaſily from underneath a ſtiffer earth, and what effect their being buried deeper would have, a wooden box was divided into three partitions, and filled with common mould taken out of a kitchen-garden. Corn known to be infeſted with theſe caterpillars was planted an inch deep in one of theſe partitions, two inches deep in another, and three inches in the third. All of them were then covered with a glaſs frame, and butterflies ſoon appeared in each of the diviſions; but they were far the moſt numerous in that where they had been buried but an inch deep. In another trial, a number of infected grains were covered with a ſtill ſtiffer earth, wetted, and preſſed down; and not any butterflies appeared there. At their firſt coming out of the ground, they are rumpled, as when taken out of a chryſalis: but after reſting a moment, they ſhake their wings, ſet them right, and ſoon take their flight.

That ſome of theſe butterflies can, and do come out of the ploughed ground which has been ſowed with infected ſeeds, is certain: but Meſſieurs Duhamel and Tillet are thoroughly ſatisfied that their number is but ſmall, that moſt of the caterpillars ſown with the grain periſh before they can reach the ſurface of the earth, and that the butterflies which proceed from granaries are the great ſource of the increaſe of this inſect: for, ſay they, the grain which contains a young caterpiller will grow, if its germe has not been damaged; and as its mealy ſubſtance is conſumed by the plant, the caterpillar muſt die for want of food. Beſides, as is proved by the laſt-mentioned experiment, the butterflies cannot pierce through a cloſe and hardened earth; which generally is the caſe of ploughed land that has been expoſed to the winter rains.

After obſerving that the two ſexes ſometimes unite a ſecond time after ſeparation; that the female depoſits her eggs almoſt immediately after they are fecundated, in ſmall parcels of from 6 to 30, and that each female lays in all from 60 to 90; adding to this, that there are generally three flights in a year, one at the latter end of May or in the beginning of June, a ſecond in Auguſt, and a third in ſome of the ſubſequent months, during which a fourth alſo, and even a fifth, have been known; we may, from the following calculation, form an idea of the aſtoniſhing multiplication of theſe inſects, and conſequently of the ravages which they muſt make where they have eſtabliſhed themſelves.

Every female produces from 60 to 90 eggs, of which 75 is the medium: but let us ſuppoſe the number to be no more than 70. Let us ſuppoſe alſo, that of thoſe 70 eggs, one half only produces females, which makes the number 35. This multiplied by 70, the number of eggs laid by each, gives for the ſecond brood, from a ſingle inſect, 2450: the half of this number, ſuppoſed to be females, is 1225, which multiplied by 70, gives 85,750 for the third brood. The half of this number, being 42,875, multiplied by 70, gives for the fourth brood, 3,001,250; and the half this, 1,500,625, multiplied by 70, gives 105,043,750 for the fifth brood: ſo that ſuppoſing five broods in a year, each female butterfly of this ſpecies that exiſts in May, produces, before the May following, no leſs than one hundred and five millions, forty three thouſand, ſeven hundred and fifty individuals of the ſame kind.

It is not agreed whether theſe inſects prefer wheat, barley or rye. The obſervations and trials made by Meſſ. Duhamel and Tillet ſeem to prove, that they attack indifferently whichever lies moſt convenient for them; and that they do not ſpare maize, when it is ſtripped of its ſtalk and laid up in a granary, where they can come at the ſoft inſide part of the grain; or even oats, though it be the common, but miſtaken opinion of the people of Angoumois, that this laſt grain is a preſervative of others, eſpecially of barley, when ſown with it, or intermixed in the ſame heap. M.

M. Tillet incloſed ſeveral ears of ſtanding oats in a wide mouthed glaſs bottle, and put into it ſome of theſe butterflies; after which he covered the mouth with a piece of fine linen. The butterflies coupled there, laid their eggs upon the ears, and ſeveral caterpillars which proceeded from thoſe eggs, actually introduced themſelves into the grains. A manifeſt proof that, though the pendent poſition of the grains of oats, whilſt growing, may be inconvenient to the female butterflies, many of whoſe eggs may be waſhed or blown off, more eaſily than from other corn, before they are fixed by the viſcous matter which faſtens them to the huſks; yet the corn-caterpillar can live upon oats. What is ſtill more extraordinary is, that grains of wheat, barley, rye, and oats, were mixed together in a glaſs veſſel, into which ſome of theſe butterflies were put; and the oats were damaged by caterpillars, as much as any of the other grain: though it is certain that theſe inſects do but little miſchief to oats in the granary; happily for the poor people who make bread of this corn.

In guarding againſt theſe inſects, the farmer has three objects: 1, to preſerve his grain for ſeed; 2, to keep it for food and market; and, 3, the total deſtruction of the inſects.

To preſerve the corn for ſeed, it ſhould be threſhed out as ſoon as poſſible, in order to prevent the transformation of the caterpillars brought from the field, which otherwiſe ſoon become butterflies, whoſe prodigious number of eggs would exceedingly increaſe the evil. For want of this precaution, two thirds of the ſtore of ſeed-corn has frequently been deſtroyed.

The ſeed ſhould either be dried in an oven, in which the heat ſhould be ſtrong enough to kill the caterpillars, without deſtroying the vegetative power of the grain; which will be properly effected by 124 degrees of heat on Farenheit's thermometer, or ſoaked in a ſtrong lye of wood aſhes and quick-lime, heated to ſuch a degree that the finger can juſt bear it. Let the corn contained in a baſket be ſtirred in this lye, and the grains ſkimmed off that float on the ſurface. When the corn has been thus ſoaked for about two minutes, the baſket which contains it ſhould then be lifted up, and ſuſpended by two poles, till the lye is drained off. The grain ſhould then be ſpread very thin on the floor of a granary to dry, while a ſecond baſket-full is prepared in the ſame manner. The corn thus ſteeped, and well dried, will keep a year, and continue fit for ſowing.

By following the above directions, corn may be preſerved from the ravages of theſe or any other ſimilar inſects that prey upon it. *Hiſtoir d'un Inſecte qui devore les Grains de l'Angoumois.*

BUTTER-JAGS, flowers of the wild trefoil.

C.

CAB CAB

CABBAGE, the name of a plant well known, and of which there are ſeveral ſpecies cultivated.

Cabbages have lately been cultivated for the food of cattle, and by ſeveral experiments found to produce a very large increaſe when managed according to the principles of the New Huſbandry. M. de Chateauvieux has been very particular in relating the ſucceſs of his experiments, which we ſhall therefore give the reader.

"I began, ſays this curious gentleman in a letter to M. du Hamel, by retrenching the dung; though the ſpot I choſe for my firſt trial had not received any for ſeveral years. It had indeed been well prepared by ploughing the preceding year, when one half of it bore barley, and the other oats. I now made it into a bed, the middle of which was directly over the laſt year's furrow. I ploughed this bed on the twenty-fifth of September, 1751, in the ſame manner as if it had been intended for wheat. I planted on it a ſingle row of white cabbages, which I watered to make them take root the better. The length of this bed was one hundred and ſixty feet, and its breadth ſix feet ſeven inches.

"That I might be able to make a juſt compariſon between the cabbages of this bed, and thoſe of the kitchen garden, I planted a ſpot of ground in the latter, the ſame day, with the ſame ſort of plants. This ſpot had been extremely well dug, and plentifully dunged by the gardener, who took all poſſible care of theſe plants during the ſummer, and weeded them as often as was neceſſary. Inſtead of cabbaging, moſt of them ran up in height: upon which I plucked them up, and planted others in their ſtead.

"I beſtowed the ſame care and culture on my row of cabbages in the bed, as if they had been wheat.

"On the ninth of March 1752, the alleys were ſtirred with the plough. On the twenty-fifth of April, I gave them a ſecond ſtirring with the cultivator. On the third of June they had a third ſtirring with the plough: and

and on the twentieth of July, I made my gardener hand-hoe them, for fear the plough ſhould damage ſeveral ſtalks of wheat which grew on the next bed, and were bent, but not lodged.

"Theſe cabbages were never watered, except once, which was at the time of planting them; and yet they were always criſp and firm, even in the hotteſt days. By this eaſy and expeditious culture, they attained all the perfection that could be deſired; and ſurpaſſed thoſe of the kitchen-garden, as much in goodneſs, as they did in bulk. Moſt of them weighed between fifteen and eighteen pounds, and the ſmalleſt between eight and ten. The weight of all the plants which grew on this bed, was 840 pounds."

The intelligent and careful cultivator Mr. John-Wynn Baker, in a report he made to the Dublin Society, tells us, that he alſo cultivated cabbages after the manner of the New Huſbandry, on a piece of ground that had bore potatoes the preceding year. It was manured with a compoſt of lime, earth, and dung, perfectly incorporated. On the ſixth and ſeventh of July 1764, he planted one row of cabbage plants on the middle of every ridge, of about an acre of ground, the plants in the rows being two feet from each other, and the rows five feet aſunder. On the ſixth of July a fine rain fell, and more on the eleventh and twelfth, which ſaved the expence of watering, and ſecured life to the plants.

On the ſeventh of Auguſt the cabbages were horſe-hoed, by taking off, at one furrow of the plough, only one ſide of each ridge, cloſe to the plants: in this manner they remained till the twenty-fifth, when the plough was ran along in the ſame furrow; by which, with the firſt furrow, the ſoil was ploughed about twenty-one inches deep. This being finiſhed, the earth was immediately returned back to the plants, which afforded them freſh nouriſhment; and in order to give their roots time enough to penetrate this freſh earth, which, by the horſe-hoeing, was become very fine mould, they were ſuffered to continue in this ſtate till the twelfth of September; when they were again horſe-hoed, by taking off the other ſide of every ridge; and on the twentieth the furrow was deepened in the ſame manner as the former, the mould immediately returned to the plants. On the eighteenth of October a ſmall furrow was thrown up to each ſide of every ridge, which finiſhed the culture, and reſtored the ridges to the form in which they were when the plants were put upon them.

The plants all grew luxuriantly; and in the hotteſt weather were infinitely more brittle in their leaves, than any in the neighbouring gardens; which is a certain indication of health in theſe kind of plants.

The horſe-hoeing was ſo effectually deſtructive to the weeds, that the expence of weeding was a mere trifle.

On the eighth of December Mr. Baker cut one row of theſe cabbages, they then beginning to decay, which is indicated by their burſting. The number was two hundred and fifty-eight, and they weighed ſixteen hundred weight, three quarters, and twenty-one pounds; which, at an average, is ſeven pounds and near ſix ounces for each cabbage.

The produce upon an acre, on weighing this row, which was five hundred and ſixteen feet long, amounted to twenty-three tons, four hundred, two quarters, and fourteen pounds; which Mr. Baker obſerves is, at leaſt, from ten to ſeventeen tons leſs than the product would have been upon an acre, could he have obtained the large, late, Dutch cabbage.

The ingenious Mr. Randall, in a treatiſe lately publiſhed, entitled Semi-Virgilian Huſbandry, has given us the following method of cultivating cabbages, according to his newly-propoſed ſyſtem, which is nothing more than the New Huſbandry executed by the ordinary implements.

The ſoil on which the cabbages are to grow, is ſuppoſed to be a loam in good heart; and as the Semi-Virgilian Huſbandry requires only that the ſoil ſhould be made exceeding fine, without the aſſiſtance of any dung, therefore the land deſtined for theſe cabbages muſt be thrown up to be fallowed, that it may enjoy all the advantages of a winter and ſummer fallow, ſo as to be exquiſitely well prepared for the reception of the plants about Old Michaelmas.

As cabbages extract their nouriſhment from a conſiderable depth, as well as from the ſurface of the ſoil, it will be neceſſary that the land ſhould be double-trenched during the time of fallowing.

The loam, immediately after harveſt, is to be turned up, and the workman is to go as deep as he can with his plough, another plough is immediately to follow in the ſame furrow with a higher earth-board, which will caſt the mould over, and bury the ſtubble, if it was not before, by ſome other method, deſtroyed: in this manner the field will, as it were, be turned upſide down, double ſpitted more than a foot deep, and the ſtubble will be ſooner rotted. The harrows muſt then make the ground as fine as the ſeaſon will at that time permit.

The next thing to be done, when the weather will admit of it, is to double trench the land, and lay it up till the ſpring in ſharp ridges.

Here Mr. Randall makes a very ſenſible and uſeful obſervation, namely, that the teams muſt not be ſuffered to go upon the ground till it is firſt tried with a ſpade, to ſee whether the ſoil is dry enough to the depth it was ploughed before; for treading the ground in any ſeaſon of the year, when it is not in order, or ſufficiently dry, is a very deſtructive practice. The ſtandard in this caſe recommended, very properly by Mr. Randall, is, when the mould crumbles or feels mellow between the finger and thumb, inſtead of adhering, ſo as to judge by the touch, whether the parts will give way to the tread, or whether the earth be in ſuch a ſtate of coheſion as to be padded under the horſes feet.

The following directions are given for performing the ridge-work, or laying up the ſoil for the winter.

The ploughman is to begin in any part of the ground he pleaſes, and go one bout, throwing the furrows in ſuch a manner, that they may form a little ridge. When this is done, the horſes muſt turn to the left, and the ſhare-point be put to the end of the trench; then go another bout in the manner already mentioned, the horſes again turning to the left, and continuing to go on in this manner, till the piece of ground is ploughed throughout. If the plough begins cloſe to a hedge, it may ſave ſome little trouble in going over more ground than is neceſſary; and where it can conveniently be done, the plough ſhould croſs the path the horſes went in the firſt operation, as this croſs-ploughing is often a means of ſtirring the baulks made by a former ploughing.

The firſt bout ſhould be drawn out as ſtrait as poſſible, as the reſt will depend upon it; and if the hedge is not ſtrait enough to allow this, the ploughman ſhould begin at ſome diſtance from it for the advantage of a ſtrait line, leaving the ſkirtings near the hedge to be laſt finiſhed. The land will now lie in gentle riſing ridges and regular valleys, ready for the third operation.

In this the ploughman is to go the very ſame ground over again, with the ſame plough, or one a little wider and higher in the earth-board, and throw the mould over the right and then over the left ſide of the firſt ridge, going four inches and a half, or five inches deep, and turning off, as before, continually to the left. This trench-work requires four good horſes to a plough; and the ſecond team, in the firſt operation, if the ground be hard, and has not been ſtirred for a long time, may require five horſes, but not more.

The ground will now lie in ſharp ridges, and deep trenches; and if the work be well executed, the bottom of the hollows or little ridges, will be near twelve, or at the very leaſt nine, inches below the baſis of the ridges, or ſurface of the ground, and about eighteen inches wide; and the diſtance from the top of one ridge to another will be near three times and a half the width of the plough, as it runs in the ground after the horſes; the breadth of the ground, which each ridge ſtands upon, being about fourteen inches.

In this ſituation the land is to remain till the month of February, when the firſt opportunity that occurs in that month, the ridges and the whole ground being of a proper dryneſs, is to be ſeized for the next operation.

In the firſt place, a pair of ox-harrows, or the heavieſt of all, in many counties called drags, are to be yoked together, and the cattle are to go a-breaſt, not in a line; but two on one ſide, and two on the other, and to walk in the trenches, having a ridge between them; by which means the harrows will move on the crown of one ridge, at the center; and the outward parts, when well guided, will reach to the top of a ridge on each ſide that which divides the cattle. The harrows, which are to go only once in a place, will greatly reduce the ſoil, and pulling down the ridges, the ſoil will be in a manner level, yet not ſo even but that the ploughman may with eaſe diſcover where the ridges ſtood. The ploughman is now to proceed in the ſame manner as when he threw the ground into ridges, keeping the plough-ſhare along the crown of a ridge, which will be viſible enough after once harrowing. When he has gone one bout, which muſt be on the tops of two ridges, the furrows will be turned to the right, and lie pretty flat on that part which was a trench before: thus proceeding throughout the field, the whole will again lie in ſingle ridges, and ſingle trenches; but, if the weather permits, as ſoon as this operation is performed, the ſoil muſt be double trenched, in the ſame manner as the ſecond ploughing of the ſecond operation, when it is laid in ridges for the winter; thus the whole field will again lie under the double work of high ridges and deep trenches.

We are now to ſuppoſe the ridge-work brought forward to the latter end of the ſpring, or the beginning of the ſummer, when weeds begin to grow plentifully.

The ridges muſt, at this time, be pulled down as before, with heavy harrows; but inſtead of going once, the ſervant muſt go twice in a place, and then uſe the lighter harrows, and afterwards the fineſt of all, in order to prepare the ground in ſuch a manner, as to induce a large crop of weeds to grow: but if the weather will permit the horſes to tread on the ground without ſpoiling it, the weeds muſt not be ſuffered to grow more then a plough can bury by going the uſual depth; and when the weeds are turned down, another plough is to follow, and to cover the furrow of the firſt, after which the land is to be harrowed down again as level as poſſible, in order to prepare it for yielding another crop of weeds.

When the ſecond crop of weeds is got to a tolerable height, it may be proper to try, with a ſpade, whether the firſt weeds, which were turned down to the bottom of the ſecond ſtratum, are ſufficiently putrified: if they are, the land is to be ploughed as before; but if they are not, the weeds now growing muſt be turned down by one ploughing by ſuch a depth only as to bury them, and the land muſt be afterwards levelled with a loaded buſh-harrow.

We may ſuppoſe, that by the middle of Auguſt, the weeds firſt turned down will be rotted; therefore at that time the third crop of weeds may be turned down by the double ſpitting, already mentioned, and left in this condition till there is occaſion to make uſe of the land.

Juſt before the time of planting the cabbages, the land muſt be laid as level as poſſible, and by frequent harrowings it will not be inferior to a garden for fineneſs.

The ground being now ready to receive the plants, it will be neceſſary to point out how they are to be raiſed and tranſplanted, which cannot be better done than in Mr. Randall's own words.

"The ground on which the cabbage-ſeed is to be ſown, muſt be exceeding fine, in great heart, and abſolutely clean of weeds, otherwiſe it will be difficult to raiſe the plants in perfection; and, in order to this, the richeſt and cleaneſt piece of ground muſt be fixed on, immediately after the ſame harveſt, when the fallow for cabbages begins, and the nurſery for the plants muſt have all the advantages of fallowing equally with that which is to receive the plants; and about the middle of July the cabbage-ſeed is to be ſown: but as huſbandmen are unacquainted with the manner of ſowing this ſeed, it will be neceſſary to employ an honeſt gardener to perform this buſineſs as it ought; and the ſame perſon may be alſo employed to pick out the young plants upon another piece of ground, in great heart, and clean of weeds, leſt they ſhould draw one another before the ſeaſon arrives when they are to be tranſplanted out for good and all, on the ground whereon they are to ſtand for a crop: one perch will raiſe plants ſufficient for more than an acre of cabbages, from two ounces of ſeed, but it is better to have a great choice, as there will be ſome puny plants in the nurſery, let the gardener or thoſe who prepared the ground, take what care they can; and the ſeed muſt be procured from Scotland, as the Scotch cabbage-ſeed is the propereſt for this vegetable, when deſigned for the uſe of cattle, as they will grow late, and to an enormous ſize, when they have all the advantages of ploughing among them, during the time of their growth.

"If the gardener is diligent, the expence of thus pricking out the tender plants, at ſix ſquare inches, on about ſix perches and a half, will be about four or five ſhillings; but if the owner can depend upon the nurſery's being clear of weeds, though the weather be very growing, there is a much cheaper method of raiſing the plants: for if the gardener, with the above two ounces of ſeed, to be ſown on ſix perches and a half, takes care to ſet out the plants with a ſmall hand-hoe, before they begin to draw one another, he may hoe up the puny, and leave none but the

the ſtouteſt plants, at a proper diſtance, ſuppoſe ſix inches, aſunder, rather under than over. While he is doing this, he may aſſiſt the plants he ſuffers to ſtand, by giving them a little mould to their ſtems, and checking any weeds that appear; by this means, the plants will grow to perfection, and need not be removed till they are tranſplanted out for the crop: and if the gardener ſows the ſeed, and leaves the plants on the ſame ground, about ſix inches aſunder, one perch will tranſplant twenty-five, and conſequently, ſix perches and about a half, will tranſplant an acre, from two ounces of ſeed on ſix perches and a half, and ſet out at ſix inches from each young plant.

"When the plants are thus raiſed on the nurſery, by either method, pricking them out, or ſetting them out with the ſmall hand-hoe, and the ſeaſon is arrived for tranſplanting them on the ground they are to ſtand on to be cabbages, the next buſineſs is to conſider the diſtance they are to ſtand from each other, when tranſplanted; and here we muſt firſt obſerve, that gardeners uſually ſet them about two feet and a half from each other throughout the piece of ground allotted for that purpoſe; and, during their ſtay on the ſoil, they only hand-hoe and earth them up, when on the bed they are tranſplanted upon, without ever giving themſelves any farther trouble about them, being no ways anxious to make them grow to the largeſt ſize which they are capable of.

"In an acre there are 4840 ſquare yards, which is about ſixty-nine yards and a half every way; but in order to proportion an acre in a piece of ground, if the length be meaſured, and the above number of ſquare yards in an acre, be divided by the length, the quotient is the breadth, and both diviſions multiplied together will give 4840 yards. Now, as gardeners plant their cabbage-plants at two feet and a half aſunder, this is allowing ſix ſquare feet and a quarter for each plant, and makes the number of about 6970 plants on an acre; and plants ſet in two rows, at two feet aſunder, and the plants ſet two feet from each other in thoſe rows, and then meaſuring out four feet and a quarter from one of thoſe rows, and ſetting two rows more in the ſame manner, and ſo on throughout the ground; when the plants are ſet in this manner, the number of cabbages will be about 6970, which is the ſame as the gardeners raiſe on an acre, and the liberty of ploughing on one ſide of every row, or in the interval, and horſe-hoeing between the narroweſt rows, or the partitions.

"When the proper ſeaſon arrives, about Old Michaelmas, or a little after, the plants are to be ſet, as above, firſt one row the length of the ground, at two feet diſtance from each other; and, when this is done, then another row in the ſame manner, at two feet diſtance from the laſt; and, when this is done, another row muſt be planted, in like manner, at the diſtance of four feet three inches from the laſt; then another row of plants, at two feet diſtance from the laſt: here, then, one ſyſtem will conſiſt of one partition of two feet, and an interval of four feet and a quarter, and of two plants to each ſyſtem: for four feet and a quarter, added to two feet, and then multiplied by two feet, the diſtance of the plants in the rows, gives the parallelogram for two plants, or twelve feet and a half; and this, divided by two, gives ſix feet and a quarter; which is the gardeners diſtance, in their practice of cultivating theſe plants, or raiſing about 6970 cabbages on an acre, which is 2130 more than can be raiſed when they are planted in ſquare yards throughout the acre.

"The ground being thus planted, we are now to conduct theſe vegetables through all the ſtages of their growth, and to help them to nutritive principles in the ſtate of their greateſt exigency; and, in order to this, at the beginning of winter the ground muſt be taken good care of, not only to keep it dry, but alſo to drain off the chilling wets from the bed of plants, which, as was ſaid before, contains two feet. The firſt thing, then, to be done, at the approach of winter, but when the ſoil is dry, is to throw the intervals up into a ſharp ridge, at two bouts, twice in a place, and as deep, each time, as the plough can go; this ridge-work, and double ſpitted, may be performed very well at two bouts, as it will allow nine inches in the middle of the interval, when the ploughman begins to turn the mould of the firſt bout upon; and then, at the ſecond bout, he will reach within three inches of the plants, if he meaſures the ground as he ought with his plough, in leaving nine inches to turn the firſt furrow on, and keeps exactly nine inches, in the ſecond bout, from the land ſide of the firſt: however, he muſt ſo manage his two bouts, as to come no nearer than three inches on the beds of plants, whilſt he is going the ſecond bout.

"This operation being over, the ground will then lie in the following form: there will be a high two-bout land in the interval, taking up five furrows in breadth, or three feet nine inches, reckoning nine inches for the breadth of the plough, as it runs in the ground; and there will be a drain, on the outſide of each bed of plants, nine inches wide, and, it being double ſpitted, or twice in a place, near a foot deep, at leaſt cut ſo with the plough, though ſome mould will unavoidably fall back again, notwithſtanding the care the ploughman may take to prevent it: and from the edge of the land ſide of each drain, or the breadth of each bed of plants, there will be two feet and a half of ground, which, through the winter, will be kept very ſafe from too much wet by means of thoſe drains; which is of great conſequence to the plants, as much cold moiſture brings on ſuch a condenſation and contraction among the component parts of this vegetable, that all the expanſive principles in the ſpring and ſummer cannot unbrace; by which a dwarf ſtate of the plant neceſſarily enſues.

"About the latter end of March, or the beginning of April, if the ground be dry, the ploughman is to go once in a place in the drain, or open trench, in order to deepen it ſtill more, and to ſtir the mould; and the ploughman need not be in any pain for the fibres of the roots, though he cuts or diſturbs ſome of them in this operation: for as the fibres, which have ſtretched out into the bed, are undiſturbed, he may cut off the outermoſt as near to the roots as he pleaſes, without doing any harm, unleſs he lets the plants down into the trench.

"When this operation is over, he muſt immediately throw down the ridge, by turning it back again, and leave an open trench in the middle of the interval, which may be done, very conveniently, at two bouts, without overthrowing the mould upon the plants; but he muſt remember to go twice in a place with his plough, to keep the ground double ſpitted, which is of great conſequence to the plants, and therefore he muſt not think of omitting it: after this operation, the ſoil will have a double trench, in the middle of the intervals, the width of twice the breadth of the plough, and about twelve inches deep, if ſome of the earth did not fall back again;

again; and there will be mould, the quantity of what is thrown out by the plough, in double ſpitting, lying between the plants and this open trench, and which will be thrown pretty near the roots of the plants; which mould is to continue there till the wants of this vegetable require us to make an alteration, when we have paid ſome attention to the partitions, and alſo to the plants themſelves.

"About the middle or latter end of April, if the ground is dry, the horſe-hoe muſt be uſed in the partitions, and the ploughman muſt go as deep with it as he poſſibly can, in order not only to diſturb the young weeds, but alſo to ſtir the earth, in the moſt effectual manner, within the reach of the fibres; but, immediately before this operation, the hand-hoe is to be uſed in the rows, between plant and plant, to check the weeds, and refreſh the mould about the roots, and the hoer muſt ſtrike his inſtrument as deep as he can; and when the weeds, any time after this, appear above ground, in the partitions, or among the plants, the horſe-hoe and hand-hoe muſt be uſed as before, but generally ſo timed, to be about a fortnight or three weeks after any alteration has been made in the intervals, that the fibres may have time, in either caſe, to heal again, inſtead of being diſturbed all at once.

"About the beginning of May the ploughman is to draw the heavy harrow, and then the finer, over the intervals, in order to pull the mould into the open trench, level, and make the whole interval fine, and to prepare it for a ploughing. Theſe harrows, being the ſame formerly mentioned, will do this buſineſs very well, without doing any harm to the plants; and if there be a good weight laid on them, they will do great execution, in pulling down the earth into the trench, and making the ground exceeding fine; which laſt article is of importance, as the plough will, in future operations, turn down this fine ſurface to a depth where the lower horizontal fibres will meet with it, and find plenty of nouriſhment therein.

"When the harrows have done their utmoſt, the ploughman is to go one bout, and throw up a ridge in the middle of the interval, if the ground is dry, and to double trench, as before; and in order to come near the plants, he may leave the breadth of about two furrows, on which to turn his bout, and then he will reach within ſix or ſeven inches of the plants with his ſhare: when this is performed throughout the ground, the harrows muſt immediately be uſed as before, and then the ploughman is to turn all the mould towards the plants in two bouts, and double trenching, by which there will again be an open deep trench in the middle of the intervals: and about a month after this he is to uſe the harrows again, if the plants do not ſpread too far into the intervals; if they do, he muſt level the ground with his plough, or the horſe-hoe, and then go one bout, and turn the mould on the breadth of a furrow and a half, ſtill going twice in a place; and then the ridge, and open furrow, on each ſide, will contain about two and thirty inches, or the breadth of three furrows and a half, and he will have gone within nine inches of the ſtems of the plants, which is near three inches farther off them than before.

"In this form the ground is to lie a month, unleſs the ſeaſon be very growing, and the weeds make a bold appearance; in that caſe, it may be neceſſary to diſturb them ſooner, by turning the ridge back again into the open trenches, and leaving the interval upon in the middle, as formerly; and about Lammas, or a little before, the ploughman is to throw down the mould, into the middle open trench, and make the intervals level and fine, and this is the laſt operation ariſing from ploughing; the ground being now to remain, without diſturbance, any farther than what enſues from the uſe of the horſe-hoe, in the intervals, after the ground is made level, as, before ſummer is over, there may come up ſome weeds, which muſt not be ſuffered to appear with impunity. It is preſumed, that due care has been taken throughout the ſeaſon of the partitions, and between plant and plant in the rows, and likewiſe on the outſides near the plants, in the intervals, where the ſhare and coulter could not reach without doing damage; and therefore, when the vegetables ſhut out the horſe-hoe, in the partitions, or where the plough could not, or durſt not, reach, the hand-hoe was to have done its office, to ſupply thoſe wants, in the beſt manner it could.

"There is another method, which we have not mentioned, to tranſplant this vegetable on the ground it is to grow into a cabbage, which is cheaper; and it is this: thoſe ploughmen, who can draw out a very ſtrait furrow, ſet off firſt, and the perſons, who are ready with the plants, put them into the trench, ſo made with the plough, at their proper diſtance from each other; and when the ploughman has gone the firſt bout, within the compaſs of three feet and a half from the ſhare point, he is to go another bout, to turn the mould into the firſt open furrow, ſo as not to bury the plants, in this operation: and he will have gone theſe two bouts, one to open the ground for the reception of the plants; and the other to give them mould, by the time the people have ſupplied the furrows with plants, ſo that they may be all ready to ſtart together again when the team returns to the head land, from making his ſecond bout.

The plants, on this occaſion, muſt be placed upright in the trench, ſtanding againſt the right ſide of it, which may be done if the plough cuts the ground true, and the mould be well ſcooped out; and this will ſhew care in the perſon that holds it, and that his inſtrument is a good one. There muſt be a perſon to carry a gage, divided into two feet, in each diviſion, ten feet in length, which will contain ſix points, the two ends, and four intermediate ones, numbered from one to ſix; which diviſion and points ſignify, that a plant muſt be placed in the open trench, directly againſt one of thoſe figures, as the gage lies upon the ground, when the man, who has the care of it, lays it down in a ſtrait line, according to his office. In order to ſhew how the plants are to be ranged, in a moſt regular manner, exactly at two feet from each other, in the rows, we will ſuppoſe the ploughman to be juſt ſetting off to go his firſt bout: in this caſe, the gager is to ſtand with his inſtrument, which may be a ſquare piece of wood, of about three inches over, or twelve in the girt, and numbered 1, 2, 3, 4, 5, 6, facing the right ſide of the plough when it ſets off; he muſt lay his right-hand juſt beyond figure 4, and his left juſt beyond figure 3, and, holding it in this manner, he will poiſe the gage very well, and lay it down, take it up, and remove it, without trouble to himſelf.

"Now, by ſtanding about five feet, on the right ſide, from the place where the plough enters, and two perſons

ſons with plants in their aprons, and a woman with a baſket full behind him, ſtanding on the leſt ſide, in this poſture of the people, the plough is then to move on, and when the ploughman has paſſed by the end of the gage, the gager is then to lay it down, but in ſuch a manner, that the end, number 1, may touch the place where the plough entered the ground, and the end, number 6, may lay in the right edge of the trench, on the mould turned out. The firſt man muſt fix his eye on figure 1, and, at the ſame time, the ſecond man on figure 4, and each of them, is to place a plant againſt his own figure; and then the firſt gardener puts down another at figure 2, and another at figure 3, and while he is doing this, the ſecond gardener ſupplies figures 5 and 6, in the very ſame manner; and, when they are ſupplying figures 3 and 6, the gager is to ſtoop down to be inſtantly ready to take up the gage, in the manner before directed, and the gardeners muſt take care to keep time with each other, that there be no delay in moving after the plough, in its progreſſive motion.

"The gager is inſtantly to remove his inſtrument, placing the left end cloſe to the laſt plant, and the other end as before; and the gardeners are to take care of the three figures belonging to their office, the firſt man managing the three firſt numbers, and the ſecond the three laſt. They may go on very faſt in this manner, if they pleaſe, and, if they are three honeſt active men, no plough can out-travel them in making one bout: and in this operation it is expected of the ploughman, that he will make his horſes ſtep on briſkly, which they may very well do with ſuch light work; for, by the ſwifter motion of the plough, there is not only leſs expence attending this culture, but the trench is better cleared of the mould, and leſt ſquare; and the furrow is thrown ſo far to the right as to be in leſs danger of falling back again, which it may otherwiſe do, from a creeping ſluggiſh motion of the plough.

"Though two active gardeners, or huſbandmen, when the latter are uſed to the nature of plants; and placing them in the ground, may get forwards as faſt as the plough; yet, in order to have the plants properly put againſt the figures, it may be better to have them take their time, and to proportion their work in ſuch a manner, that they may finiſh by the time the team is at their heels, in ending the ſecond bout. The gager, and the two gardeners, need not be afraid of too much ſtooping; for the gager, when he ſtoops to put down his gage, has walked five feet, from the laſt place where he took it up, and, in fact, is only diverſion and exerciſe for him; and the firſt gardener, when he ſtoops to put down his three plants, ſtepping along at the ſame time, in that poſture, has ſix feet of ground to walk upright upon, which he may diſpatch very nimbly, if occaſion requires it; and the ſecond gardener, in like manner; and as a perſon attends them at their backs with a baſket of plants, they may, without loſs of time, be ſupplied, while they are walking, and take leſs or more into their aprons, or hands, as they ſee convenient, and conſiſtent with diſpatch.

"When the gager gets up to the far end of the ground, he muſt remember to keep on the furrow ſide of the plough, that is, on that ſide towards which the mould is turned; and the ploughman is now to receive farther directions how to proceed, when he has gone the two bouts, mentioned before. He was deſired to draw out a very ſtrait furrow when he firſt went up the ground, by taking ſight of a tree, buſh, or any other mark, exactly in the middle of the ground, and directly oppoſite to the place where he is to ſet off from, and which he judges to be in the middle; or he may uſe any method agreeable to himſelf, provided a ſtrait line be only drawn out by the plough, for on this depends the regularity of all the reſt of his bouts, and the operations of horſe-hoeing and ploughing during the growth of the cabbages. The firſt furrow being thus drawn out, the next buſineſs is, to turn the horſes to the right, and then to meaſure three feet and a half, from the edge of the land ſide of the firſt furrow, or that edge cut with the coulter; and, making a mark at the end of three feet and a half, he muſt put the ſhare point in there, and come ſtrait back again, keeping exactly three feet and a half from the fat edge of the other furrow; and then, as was ſaid before, he muſt go a ſecond bout, to turn the mould into the open furrow where the plants are placed, which he may very well do without doing them any harm: if he proportions the depth of the furrows, where the plants are put, to their ſize, as they will be greater or leſs, juſt as the ſeaſon has been for their growth on the beds whereon they grew.

"When all this is performed, and the ploughman is ready to ſet off again, in order to make another bout, he is to turn to the right, to draw out another furrow, which is to receive the plants which muſt ſtand four feet and a quarter from the row of plants now on his right-hand; to do which he is to conſider, that the near edge of the open furrow next to him is the breadth of two furrows, or eighteen inches, from that row of plants; and taking eighteen inches from four feet and a quarter, the remainder is thirty-three inches; and becauſe the plants muſt ſtand on the furrow ſide, therefore we muſt add the breadth of the plough, which is nine inches, to the above thirty-three, which then will make three feet and a half from the edge of the open furrow next to him; and now meaſuring three feet and a half from that furrow, he muſt make a mark, and go his bout, turning to the right, and making the ſame mark from the outtermoſt furrow as before, and ſo proceeding ſtrait back again.

"He is now to go another bout, to earth his plants, and when he has done this, he muſt ſtill turn to the right, and make a halt on the head land, to conſider what is next to be done: he knows the edge of the open furrow, now on his right-hand, and next to him is eighteen inches from the neareſt row of plants, and that the furrow he is going to open is for the plants to ſtand juſt two feet from the laſt row; and therefore taking eighteen from twenty-four, the remainder is ſix: and becauſe the breadth of the plough is nine, therefore he muſt meaſure fifteen inches from the edge of that open furrow next to him, and making a mark there, that is the place where he is to ſet off: and when he gets to the far end of the ground, he muſt turn to the right, and meaſure off fifteen inches from the edge of that open furrow next to him, as he comes down again: he is to go another bout to earth his plants, and then all things will be eaſy to him, as it will be only repeating what he did before; for as he is now going another bout, he is to meaſure three feet and a half, from the near edge of the open furrow next to him on his right-hand, and go ſtrait up, and turning ſtill to the right-hand, he muſt

meaſure

meaſure the ſame diſtance, as he comes down again from that open furrow, and when he has made another bout to earth thoſe plants, he meaſures fifteen inches from the edge of that furrow; and when the plants are put into that he is now making and earthed, he then proceeds to meaſure off three feet and a half, which forms the interval, and ſo on earthing, and then meaſuring fifteen inches alternately with the other, for the partitions, till all is finiſhed.

"By which operations the whole ground will be planted with two rows, at two feet the partitions, and four feet and a quarter the intervals. Thus, then, upon the whole of theſe directions, when he firſt ſets off, and gets to the far end, and, turning to the right, he meaſures three feet and a half; when he has earthed plants, he meaſures three feet and a half for the next bout to receive the plants; and, earthing theſe, he meaſures fifteen inches for another row of plants; and, earthing theſe, he meaſures three feet and a half; and earthing theſe, he meaſures fifteen inches; and ſo on, alternately, three feet and a half, and earthing; then fifteen inches, and earthing; then three feet and a half again."

The farmer will, doubtleſs, be glad to know what crop he is to expect from his land after all his labour: he has already been informed, that the number of cabbages on an acre, if they have all ſtood to maturity, will be ſix thouſand, nine hundred and ſeventy: theſe may be allowed to weigh, one with another upon a medium, three quarters of a ſtone each; and if an ox be allowed to eat nine ſtone a day, that is, twelve cabbages, then ſix oxen will live three months on one acre of them; ſo that ſuppoſing one acre of turnips, raiſed in the common method of huſbandry, to be ſufficient during the ſame ſpace of time for two oxen, we may ſtill expect, in proportion, three times more benefit from the cabbages than from the turnips.

Mr. Randall aſſures us, that the oxen will grow very fat upon ſuch food; that he has given it to many cows for a long time together, without perceiving the leaſt diſagreeable taſte, either in the milk or butter: on the contrary, the milk was rather richer and ſweeter; and that both oxen and cows are exceedingly fond of this food. The ſame may be ſaid of ſheep, which improve in their fleſh very faſt, and grow ſurprizingly fat on cabbages; yet has the mutton no diſagreeable taſte; ſo that there is perhaps no vegetable which will raiſe lean ſheep of the largeſt breed ſooner than cabbages. *Randall's Semi-Virgilian Huſbandry, p.* 315.

CADDOW, a name given in the jack-daw, in ſome of the northern counties of England.

CADMA, the leaſt of the pigs which a ſow has at one farrowing; for they have generally one which is remarkably leſs than the reſt.

CALF, the young of a cow.

There are two ways of breeding thoſe calves you deſign to rear; the one is to let them run with the dam all the year, which is the common way uſed in the cheap breeding countries, which they reckon makes the beſt cattle; and the other way is, to take them from the dams after they have ſucked about a fortnight: then they teach them to drink flet or ſkimmed milk, which they make juſt warm for them, it being very dangerous to give it them too hot. The beſt time for weaning of calves is from January to May. Let your calves have milk for about twelve weeks; only a fortnight before you wean them from milk, let water be mixed with the milk; and after your calf hath drank milk about a month, take ſome of the freſheſt, ſweeteſt hay you have, and put little wiſps of it into ſome cleft ſticks, which place ſo as the calf may eaſily come at them to learn to eat; and after Lady-day, when the weather is fair, turn your calves to graſs, taking them in a few nights at firſt, giving them milk and water, and ſometimes giving the ſame to them in a pail in the field, till you find they are able to feed themſelves, ſo as not to deſire it: but by no means let your graſs be too rank, but ſhort and ſweet, that they may get it with ſome labour. All wean their calves at graſs; for if you wean them in the houſe with hay and water, it is apt to make them big-bellied, and to rot; and when you have reſolved which of the males to keep for bulls, let the others be gelt for oxen, which the ſooner you do the better: when they are about ten or twenty days old, is the beſt time, and leaſt dangerous.

In Hertfordſhire, Eſſex, and moſt places near London, they commonly fat all their calves for the butcher, becauſe they have there a good market for them, and the lands are not ſo profitable to breed on as in cheaper countries; a good calf there often ſelling for as much as a good heifer, eſpecially if they are very fat and white, which they take a great deal of care to make them. Their way of doing this is by keeping them clean, giving them freſh litter every day, which they lay upon their old litter; for they clear out their coops but two or three times in a year, and moſt commonly at a time when they have no calves in them: they conſtantly alſo let them have a large chalk-ſtone or two to lick, which they bore a hole through, and hang up by a ſtring in a corner of the coop, which prevents their fouling it with dung and urine. They alſo obſerve to ſet their coops where they may have as little ſun come to them as they can, that they be not made cloſe and ſtifling, and that they ſtand a yard above the ground, that the urine may run from them: and to make them white, they often let them blood when they are about a month old, and a little before they kill them; and becauſe they are often looſe, they do not let them ſuck their fill; but inſtead of it they ſometimes give them chalk ſcraped into milk, which they pour down with a horn; alſo ſalt and water, and ſometimes they cold bathe them, and give them bole-amoniac and chalk, which they moiſten with milk, and make it into balls, and give it them. If a cow will not let a ſtrange calf ſuck her, rub both hers and the calf's noſe with a little brandy. *Mortimer's Huſbandry, vol.* I. *pag.* 228.

A young calf is left with its dam the firſt five or ſix days, that it may be kept always warm, and ſuck whenever it pleaſes: but if in thoſe five or ſix days it grows and gathers ſtrength, there is a neceſſity for making a ſeparation, as he would exhauſt the cow if left always with her. Sucking two or three times a day will now be ſufficient. If you intend to fatten him ſpeedily, and, at the ſame time, render his fleſh fine and delicate, let him have every day raw eggs, boiled milk, and the crumbs of bread: by this means the fleſh, at the end of four or five weeks will be excellent. Calves, therefore, intended for the butcher ſhould not ſuck above thirty or forty days; but thoſe deſigned for the dam for two months at leaſt; as the more they ſuck, the ſtronger and larger they will prove. The beſt for bringing up are thoſe calved in the months of April, May, and June. It is

ſeldom

ſeldom that thoſe which come later acquire ſufficient vigour to ſupport them during the inclemency of the following winter; the cold cauſing them to droop, and many of them to die. Thus calves deſigned for keeping ſhould be weaned at two, three, or four months; but before taking them totally from the milk, a little good graſs, or chopped hay, ſhould be given them, that they may become accuſtomed to ſuch aliment; for when they are to be entirely ſeparated from their dam, they muſt never be ſuffered to come near her either in the ſtill or paſture, whither they ſhould be ſent every day, and remain there, during the ſummer, from morning to evening; but at the ſetting in of the cold weather in autumn, they muſt not be let out till late in the morning, and brought back early in the evening. And as the pinching cold of winter will be extremely detrimental to them, they ſhould be kept very warm in a cow-houſe, and well ſupplied with water; ſaintfoin, lucern, &c. ſhould be mixed with their common hay. They muſt be let out only in warm weather. A great deal of care is neceſſary to bring them through the firſt winter, which is the moſt dangerous period of their lives; for they will acquire ſo much ſtrength during the following ſummer, that they will have nothing to fear from the cold of a ſecond winter. *Buffon's Hiſtoire Naturelle, tom.* IV.

The deſire of profiting by the milk of the cow, is often the cauſe of the calf's being too early weaned. A month or two more, in ſhort the time required by nature, would ſtrengthen it in its youth; it would grow more ſucceſsfully, and, in time, fetch a profit with good intereſt. But this is hardly done any where. No ſooner is it believed that it can ſubſiſt without the mother's milk, than the farmer thinks he gains a great deal by weaning it: ill fed, and infirm, it grows at beſt to be a ſorry bull, or feeble bullock, from which little profit, and much leſs ſervice, can be expected.

Ignorance and want of reflection form the principal ſource of this abuſe! People do not know, or do not reflect, that the vital flame, incloſed in the heart of a new-born animal, muſt be cheriſhed and augmented; that it attracts and is nouriſhed by that contained in the milk; that this vital flame, weak at firſt, would ſcarce have power to ſeparate the auxiliary fire from the milky particles with which it is incorporated, if milk was a leſs delicate ſubſtance than nature hath formed it for this firſt ſervice; but in proportion as the vital fire acquires force, the milk grows thick, becauſe its groſſer particles are deſtined for forming and conſolidating the body of the animal. When the vital flame is arrived at ſuch a degree, as to be ſuperior to the ſuccours which the milk can afford, nature excites the animal to ſeek a more ſolid nouriſhment, and then, but not before, is the time for weaning it. For, by anticipating that time, you run the riſque of leaving the animal imperfect in its interior parts: the aliment which is adminiſtered being above its ſtrength, it cannot perform a perfect digeſtion, and the nouriſhment it receives is ſo much the leſs; becauſe, in all natural bodies, the ſtrongeſt juices, and the moſt efficacious qualities are always mixed, and, as it were, blended with the hardeſt particles. Hence it happens, that a ſickly animal does not derive from the ſame food ſo much nouriſhment as an animal in health. Indeed the vital flame, too much employed in reſiſting the attacks of the corrupted humours, hath not force enough to extract from the aliment the neceſſary auxiliary fire it contains. Beſides, the food being only in a part diſſolved, paſſes away in the excrements, and forms only a thin inefficacious manure.

As therefore we may be aſſured, that by weaning a calf too early, it will continue infirm and of ſmall value, ſo by leaving it with its mother, as long as its conſtitution requires, we may expect it will become ſtrong and vigorous; and by following this method, we can hardly fail of raiſing a breed of cattle, that will redound both to the honour and profit of the farmer.

Young calves are apt to be attacked by inſects, which diſturb and torment them, and, at the ſame time, prevent their fattening. In order to preſerve them from theſe inſects, and even cure them when they are attacked, it will be proper to prepare an ointment of melted hogs-lard and quickſilver, well rubbed together in a marble or iron mortar. Spread this ointment upon a linen cloth, which wrap up in three folds, and ſtitch it for a collar to the calves. It will not only cure them, but alſo diſperſe the inſects.

There is no better nouriſhment for young calves, than vetches ſoaked in water till they ſwell; but obſerve to ſteep no more than will ſerve them for once; becauſe when they continue moiſt for any conſiderable time, they are apt to grow ſour, and would then do them more harm than good. *Journal Oeconomique.*

CALKINS, a name given in ſome parts to a ſort of horſes ſhoes, made for froſty weather.

Theſe ſhoes, by forcing the horſe to tread wholly on the toes of his hind feet, are apt to occaſion bleymes, and ruin the back ſinews. The farrier, therefore, ſhould be ordered to pare the horn a little low at the heel, and turn down the ſponge upon the corner of the anvil, ſo as to make the calkin reſemble the point of a hare's ear, which will remove the conſequences often attending the common ſquare calkin.

CALTHA, the marſh marygold, the name of a perennial plant, growing naturally in the low meadows in many parts of England.

M. du Hamel recommends this plant to the notice of farmers, as very uſeful to be cultivated as a winter paſture for cattle; and experience has juſtified his recommendation. Perhaps it might prove as uſeful in this country as in France, eſpecially as cattle are known to be extremely fond of it, and the plant might be eaſily cultivated.

CAMMOCK, the name of a troubleſome plant infeſting arable lands; but more generally known by the name of reſt-harrow. *See the article* REST-HARROW.

CANARY-*Seed*, the name of a ſmall ſeed produced by a gramineous plant, cultivated in ſome parts of England.

A correſpondent of the editors of the Muſeum Ruſticum, has given us the method practiſed by the farmers of the iſland of Thanet, in the culture of canary-ſeed. He obſerves, that they generally chuſe to ſow it in freſh land; that is, ſuch as has only borne graſs. After ploughing up the lay, and bringing the land into tolerable rough tilth, they ſow it with peas; theſe are kept clean hoed as uſual, and yield a good crop. The next year the land is well ploughed, and planted with horſe-beans, which thrive well in that iſland. Theſe two crops effectually kill the greenſward, or graſs, take off the rankneſs of the ſoil; and the frequent hoeings, which are neceſſary to keep the weeds under, bring the land

into fine tilth. After the beans are off, a thorough ploughing is given to the land, and in that condition it remains till the ſpring: about the beginning of March, if the weather be fine, and the ſeaſon dry, the land is ploughed for the laſt time; immediately after which the canary-ſeed is ſown.

The farmers in that iſland uſed formerly to ſow canary-ſeed with a broad caſt, ſpreading it all over the land; but when this was the practice, they found it very difficult to hoe and keep the plants clean from weeds: at preſent they ſow it in furrows, made a-croſs the land, conſtantly taking care to make the ridges between the furrows as ſharp as poſſible: by this means the ſeed, which is ſown by hand, ſlips from the ſides and tops of the ridges in the furrows, and the plants come up in regular rows. The plants muſt be kept very clear of weeds by means of the hoe, weeding-hook, &c. and if it be a wet ſummer, the intervals muſt be hoed ſeveral times; but of this the intelligent farmer is the beſt judge.

Three pecks of ſeed are, in general, enough to ſow an acre, ſometimes more, and often leſs. The canary-ſeed ſeldom comes on till the wheat harveſt is entirely over, and the corn houſed: but it muſt be obſerved, that the wheat harveſt is generally very early in that iſland. It is reaped with a hook, and as faſt as it is cut, the reapers lay it on the land in wads, as they call them, or parcels about the quantity of half a ſheaf of wheat unbound: in this manner, if the weather be favourable, it is left near a fortnight, at the end of which time, the wads muſt be turned, that the other ſide may be dried. If the weather be very wet, they muſt be turned oftener, to prevent the ſeed from ſprouting.

The price of reaping canary in that iſland is from ſix to eleven ſhillings per acre; and the price of threſhing and dreſſing it is five or ſix ſhillings a quarter. According to the goodneſs of the land, and the tillage that has been beſtowed upon it, the farmers there expect their return to be from twenty-five to fifty buſhels per acre; but the common crop is from thirty to thirty-four. It muſt, however, be obſerved that the farmers never pay ſo much as ten or eleven ſhilling per acre for reaping this crop, unleſs the canary be very much lodged and tangled, which it often is, owing to the land in which it grows being freſh, rich, and rank, and to the high winds to which that iſland is ſubject.

They ſow ſucceſſive crops on the ſame land for eight or ten years; and ſowing canary would be a very great improvement to lands which lie convenient for water carriage to London markets, was it not a crop the farmer ought by no means to depend upon, not only becauſe the return, or quantity it yields, varies greatly, but alſo on account of the fluctuation in the price of this ſeed in the London markets, where the greateſt and indeed almoſt the whole demand is. *Muſeum Ruſticum*, *vol.* I. *p.* 22.

CANKER, a ſmall ſpeck made by a ſharp humour, which gnaws the fleſh almoſt like a cauſtic.

This diſtemper often attacks the foot of a horſe, and generally proceeds from thruſhes, when they prove rotten and putrid, though many other cauſes may produce this diſorder. The method uſed by farriers for the cure is generally with hot oils, ſuch as vitriol, aqua fortis, and butter of antimony, which are very proper to keep down the riſing fleſh, and ſhould be uſed daily till the fungus is ſuppreſſed, when once in two days will be ſufficient, ſtrewing red precipitate powder over the new grown fleſh, till the ſole begins to grow.

There is one great error committed often in this cure, which is, in not having ſufficient regard to the hoof; for it ſhould not only be cut off, wherever it preſſes upon the tender parts, but ſhould be kept ſoft with linſeed oil; and as often as it is dreſſed, bathe the hoof, all round the coronet, with chamberlye. Purging is very proper to complete the cure. *Bartlet's Farriery*, *p.* 314.

CANCER, in trees, implies a wound or blemiſh in the trunk, which does not heal up naturally, but will increaſe and damage, if not endanger, the whole tree.

The canker in fruit trees is moſt commonly occaſioned by wet, which gets in at the cleft where the tree was grafted, or at ſome other wound which has been neglected: but it alſo proceeds ſometimes from the ſoils not agreeing with the nature of the tree.

If this diſtemper be only ſuperficial, ariſing from a bruiſe, for example, which the bark may have received, it may be cured by cutting the injured part out with a ſharp knife, and then binding over it a mixture of cow-dung and earth, tied on with a wiſp of hay, likewiſe daubed with cow-dung. This muſt be done before the ſap begins to riſe; for otherwiſe the bark will peel, looſen, and wither much farther than the bruiſe, to the great hazard of the whole tree, eſpecially if the ſtem be the part affected: for as to a bruiſed branch, the beſt way is to lop it off at once, if there be the leaſt ſuſpicion of danger. But when the canker has been bred in the tree, or when it has extended from the trunk to the branches, or from the branches to the trunk, ſo that after cutting away to the very quick, there till remains an eye, or ſpeck, like that which is ſometimes ſeen to run through a whole plant of diſtempered corn, the ſhorteſt way is, to commit the tree to the fire, and to plant another in its ſtead. Mr. Nourſe is indeed inclined to think that, if the canker has not penetrated too far the tree or ſtock, ſuppoſing it to be of the apple kind, it may poſſibly be ſaved, by regrafting it with a winter quinnin, a boderan crab, a boon apple, or a golden pippen; neither of which he had obſerved ever to canker: but how accurate his obſervations may have been in that reſpect, we ſhall not pretend to determine. Certainly it may be worth while to try a change of fruit in all ſuch caſes, if they are not abſolutely deſperate. He aſſerts, upon his own experience, that the apple which we call a woodcock, is no way apt to canker, or to be blaſted.

This, if it be fact, renders it by ſo much the more worthy of cultivation, as it is a great and conſtant bearer, and yields an excellent juice. The misfortune is here, as well as in the attempts which have been made to ſuit the ſoil and the fruit, that each of theſe is diſtinguiſhed, either by ſuch general appellations and deſcriptions as ſerve only to puzzle the huſbandman when he comes to real practice, or by names which are not known out of the places where they are uſed. Doctor Cullen will render a great ſervice to mankind, if he ſhould happily ſucceed in that important point, which, if we are rightly informed, is the object of his preſent ſtudies; viz. to aſcertain by an exact analyſis, which no one can be better qualified to do with the utmoſt preciſion, what are the component particles of each different ſpecies of ſoil, and what proportion they bear to each other. This, diveſted of that parade of ſcience, and of ſcientific terms,

which

which the learned are too apt to diſplay, and which ſerves only to embarraſs common underſtandings, will, ſhould ſuch a work appear, as it is hoped that it will ſoon, anſwer a very eſſential purpoſe in agriculture, as well as lay a fine foundation for uſeful entertainment to gentlemen whoſe leiſure permits them to proſecute ſuch ſtudies. But the taſk, conſidered in all its various branches, is arduous indeed! worthy of that able phyſician, we uſe the word here in its moſt extenſive and moſt proper meaning, and ſkilful chemiſt, whoſe love for the welfare of mankind has prompted him to undertake it.

Mr. Worlidge aſſures us, that he himſelf cured a tree deſperately diſeaſed with the canker, by cutting off as many as he could of the cankered boughs, laying its roots bare during all the winter, and applying to them in the ſpring a great quantity of ſwines dung, not too new, mixed with the earth, which was then returned into its former hole. If this does not do, he condemns the tree to be grubbed up, as being paſt recovery. *Nurſe's Diſcourſe in the Benefits and Improvement of Huſbandry, page* 138. *Worlidge's Syſtema Agriculturæ, cap.* viii. *ſect.* ii.

CAPELLETS, in horſes, are particular ſwellings which thoſe animals are ſubject to, of a wenny nature, which grow on the heel of the hock, and on the point of the elbow, they ariſe from bruiſes and other accidents, and when this is the caſe, ſhould be treated with vinegar and other repellers; but when they grow gradually on both heels or elbows, we may then ſuſpect the blood and juices to be in fault; that ſome of the veſſels are broke, and the juices extravaſated. In this caſe the ſuppuration ſhould be promoted, by rubbing the part with marſhmallow ointment; and when matter is formed the ſkin ſhould be opened with a lancet, in ſome dependent part towards one ſide, to avoid a ſcar: the dreſſings may be turpentine, honey, and tincture of myrrh. The relaxed ſkin may be bathed with equal parts of ſpirit of wine and vinegar; to which an eighth part of oil of vitriol may be added. The contents of theſe tumours are various, ſometimes watery, at others ſuety, or like thick paſte; which if care be not taken to digeſt out properly with the bag, will frequently collect again: was it not for the diſfigurement, the ſhorteſt method would be to extirpate them with a knife, which, if artfully executed, and the ſkin properly preſerved, would leave very little deformity.

When thoſe tumours proceed from an indiſpoſition of the blood, they are beſt let alone, eſpecially thoſe of the watery kind, which will often wear off inſenſibly, without any applications: but when they are like to prove tedious, you ſhould endeavour to diſperſe them by bathing the parts with repellers, and have recourſe to rowels, purges, and diuretic medicines, to carry off the ſuperfluous juices and correct the blood. *Bartlet's Farriery, p.* 277.

CAPO, a word uſed in Cheſhire, to ſignify a working houſe.

CAPON, a cock chicken gelded as ſoon as left by the hen, or at leaſt as ſoon as he begins to crow.

Capons are very uſeful to lead chickens, ducklings, young turkeys, pheaſants, and partridges, which they will do better than the hen, and at the ſame time make a ſtouter defence againſt kites and buzzards. The largeneſs of their body is alſo of great advantage, as they will cover between thirty and forty of them.

CARBERRY, a name given in ſome parts of England to the gooſeberry.

CARCASE, a name generally given to the body of a horſe.

The carcaſe of a horſe ought not to be too ſmall and ſlender; for a ſmall carcaſed horſe is generally weak. On the other hand, a very large carcaſed horſe proves often heavy and unactive, and when he happens to be underlimbed, it is reckoned a great fault, though this remark often fails, and horſes, that have been reckoned very much underlimbed, have proved as ſtrong, and fully as ſerviceable as any other.

A low back is another fault that almoſt every body complains of, and indicates weakneſs, though a moderate ſinking below the withers is not at all amiſs, if the back be otherwiſe ſtrait. When this ſinking is not great, the forehand generally riſes well. But when a horſe has a low back, and is higher behind than before, it is not only ugly, but ſuch horſes are generally weak, are apt to be pinched in their ſhoulders, and have an aukward way of going, owing to the heavineſs of their hind parts, which hinders them from geting on.

Some are fond of horſes which are home ribed, which is indeed a property that denotes both beauty and ſtrength, as thoſe that are open ribed are looked upon to be weak and looſe; but in ſome horſes the ſhort ribs approach ſo near the haunches, that they have ſcarce liberty to breathe, and ſuch horſes are the moſt out of wind of any other when put upon hard exerciſe, and eaſily go broken winded. But a horſe that is open and looſe in his flanks, like a grey-hound, is liable to many diſadvantages, which it would be tedious here to relate; ſuch are always narrow over the chine, have little or no belly but what is forced by art and feeding; and though we find ſome of this kind more vigorous than others, and even exceed all expectation, yet the generality of ſuch horſes are ſeldom fit to carry a great weight, or to hold out in hard riding. Some are great admirers of ſhort backed horſes, which is a right way of judging, ſo far as this ſtands in oppoſition to a very long back. But ſome horſes are ſo very ſhort, notwithſtanding they are otherwiſe of a good ſize, that they ſeem to be loſt under common furniture. But when a tall horſe happens to have a ſhort carcaſe, and very long legs, like a ſpider, ſuch a horſe is ſeldom good for much. If a horſe's back be ſhort, his whole body and limbs ought to be ſhort, and then it denotes ſtrength and firmneſs; but moſt of theſe make but a ſlow progreſs on a journey, though they will endure and hold out as long as any other, unleſs they are urged on with horſes of greater ſpeed.

It always denotes ſtrength in a horſe, when his carcaſe is of a moderate ſize, his ribs large, his flanks not hollow but ſmooth and full, with a ſtrait back, or but a very little ſinking, his hinder parts, or uppermoſt haunches not riſing higher than his ſhoulders. *Gibſon on horſes, vol.* I. *pag.* 31.

CARDOON, a kind of wild artichoke, propagated only by its ſeed, which is of an oval form, about as big as a grain of wheat, of a very dark green, or blackiſh colour, and marked with black ſtreaks from one end to the other. There are two ſeaſons for ſowing it: the firſt is from the middle to the end of April; and the other about a month later. The ſoil ſhould be rich, deep, and fine. In a bed of ſuch mould, four or five feet wide, two trenches ſhould be opened, a foot wide,

ſix inches deep, and at leaſt three feet aſunder: or, to anſwer the ſame intention, the rows of holes of the ſame depth ſhould be dug ſtrait by a line ſtretched along the bed. Theſe holes ſhould be three feet aſunder, and in quincunx order; or, if a trench is uſed, the quincunx form ſhould be obſerved in ſowing the ſeeds, which is performed in the following manner. Five or ſix of the ſeeds are dropped nearly together, at the diſtances before mentioned, and then covered over: not with a deſign to let ſo many plants grow cloſe together in a thick cluſter; but, as the growth of theſe ſeeds is ſomewhat precarious, to be the more certain of having two or three plants at each ſtated diſtance: for if all of them come up, they are immediately thinned to that number; and if they miſcarry entirely in any one ſpot, the chaſm is filled up with plants taken from another place, generally a hot-bed, on which ſome of theſe ſeeds are moſt commonly ſown when its heat is expiring, for a recruit in a caſe of need. The firſt ſowing will generally come up in three weeks, and the latter in about fifteen days. Great care muſt be taken to keep thoſe plants clear from weeds, and to water them frequently, in order to make them increaſe in bulk, and not run to ſeed. But this intention will doubtleſs be much better anſwered in every reſpect by a judicious application of the principles of the New Huſbandry; we mean, by deep and frequent ſtirring of the ground on each ſide of the bed, letting the ſhare or ſpade approach to within a very few inches of the plants.

Towards the latter end of October, the cardoons thus cultivated will be fit for tying up, in order to be blanched. In order to this, a dry day ſhould be choſen, when all the leaves of each cluſter being collected cloſe together, wiſps of ſtraw, or long litter, ſhould be twiſted round them ſo as to prevent the acceſs of the air to any part of them, except their very top, which ſhould be left open. In a fortnight or three weeks the plants thus covered will become white and fit to eat.

This tying up, and blanching of cardoons, may be continued till the winter approaches, and then thoſe who are ſo fond of them as to think it worth their while to be at the trouble, may take them up, with ſome earth about their roots, and remove them into a green-houſe, if they have one, or into a cellar, and by that means keep them for uſe all the winter. Some of theſe may be replanted in the ſpring, in an open border, as before, to ſeed in June or July; or they may be cut down to the ground, when thus planted anew, and their ſecond year's ſhoots may be tied up and whitened as before.

Beſides the uſe which the Italians, French, and Spaniards, make of this cardoon, in eating it raw with pepper, ſalt, oil, and vinegar, many think it preferable to celery, when ſtewed, becauſe it is mellower, and much more tender.

CARLICK, the ſame with charlock. *See the article* CHARLOCK.

CARPET-WAY, a green-way, or path left in an arable field, without being ploughed.

CANE, a hollow place where water ſtands. It alſo implies a wood of alder, or other aquatic trees in a moiſt boggy place.

CARRIAGE, a general name for carts, waggons, and other vehicles, employed in carrying timber, corn, perſons, &c. from one place to another.

CARRIAGE, alſo ſignifies a furrow, or trench, for conveying of water to overflow and improve meadow-land. It is diſtinguiſhed into two ſorts; the main carriage, which ſhould be made with a convenient deſcent; and the leſſer carriages, which ſhould be ſhallow, and as many in number as poſſible.

CARROT, the name of a root too well known to need any deſcription here.

The Society for the Encouragement of Arts, &c. being perſuaded that the cultivation of carrots for the food of cattle could not fail of being advantageous to the farmer, publiſhed a premium of twenty pounds to the perſon who ſhould ſow the greateſt number of acres with carrots, for the feeding of cattle only; adding, that it was expected the perſon who received the premium ſhould give an account of the ſoil, culture, time of taking up, and their effects on the cattle fed with them.

This premium was accordingly given in the year 1766 to Mr. Robert Billing, a very intelligent farmer at Weaſenham in Norfolk; he having ſowed thirty acres and two rods of land with carrots, for feeding cattle only. At the ſame time he ſent an account of the methods he uſed in the culture of his carrots, which was ſo well approved of by the Society, that it was publiſhed at their requeſt: an abſtract therefore of this pamphlet muſt, we preſume, be very acceptable to the reader.

Mr. Billing obſerves, that the uſe of carrots for the winter feed of cattle has been long known and practiſed in the eaſtern parts of Suffolk, where it is common to make carrots ſerve the ſame purpoſe turnips have many years done in moſt parts of the county of Norfolk; beſides, that many are ſent from thence to the London market: but carrots never have been ſown in the latter county, for the maintenance of cattle, till he tried a ſmall parcel in the year 1761, and another in the year 1762.

He thought it prudent, he ſays, to make thoſe trials before he became a candidate for the premium offered by the Society; the hopes of deſerving which encouraged him to venture a pretty large and unuſual expence, as well as the loſs of a great part of his winter crop, and which has thus become the means of making known, in his part of the country, a ſpecies of huſbandry with which they had before no acquaintance but by hearſay, being above fifty miles from the country where it had before prevailed.

In the year 1763, he ſowed thirty acres and an half by menſuration.

This quantity of land lying in three parcels, one, of thirteen acres, bore wheat in the year 1762; one, of half an acre only, had borne clover; and the laſt, of ſeventeen acres, turnips that year. The piece of thirteen acres is a cold loamy ſoil, ſhallow, and upon a ſort of loamy gravel. The half acre is a ſoil much mixed, upon a moiſt clay, the ſeventeen acres may be divided into two parts, the one of fourteen acres, and the other of three. Both are a light and dry ſoil, newly improved with a marle; the former, an exceeding good tempered ſoil, upon a marle; the other, a ſhallow black ſand, upon a kind of imperfect grit-ſtone, called, in Norfolk, a carr-ſtone.

Previous to giving an account of the ſucceſs of his crop of carrots, and of the uſe he made of them in feeding cattle, he deſcribes the manner in which he cultivated

tivated theſe ſeveral pieces of land, founded as well on the beſt information he was able to procure, as upon the obſervation afforded him by his own experience of the former year.

The wheat and clover ſtubble he ſplit down with the plough early in the preceding November, and is ſatisfied, from all the obſervations he has made ſince he firſt begun the cultivation, that whether the wheat ſtubble be, as it is called in Norfolk, flat work, or in ridges, or the carrots are to be ſown after clover or rye-graſs, the land cannot be ploughed too early; ſo that the froſt and ſnow may have their full effect in mellowing the ground for the reception of ſo ſmall a ſeed; and this is the more neceſſary to be attended to, the ſtiffer and tougher the ſoil ſhall chance to be.

The land that had been turnips he let alone till the end of January, or beginning of February, thinking this time enough, becauſe the earth was thoroughly cleaned by the cultivation and ſummer hoeing neceſſary for the crop of turnips.

Of the thirteen acres of wheat ſtubble, ſix were dunged for wheat, but not for carrots; four and a half not dunged at all; and two and a half for the carrot crop only. The clover land was dunged for the carrots: and of the ſeventeen acres that had been turnips in 1762, part had been tathed for the turnips, that is, where ſheep had been folded; and the whole crop of turnips was fed off by ſheep and neat cattle.

Four pounds of ſeed on an acre is ſufficient: but as the ſeed is very ſmall, light, and hard to ſeparate and diſperſe equally on the ground, he was at firſt a good deal puzzled how to overcome this difficulty; and though he was adviſed to make uſe of a mixture of ſand, he did not find it anſwer, becauſe the weight of the ſand carried it all to the bottom of the ſeed-cot: he ſows it therefore now unmixed, as they do turnips, after having forced it through a fine chaff-ſieve by rubbing.

It will be three weeks, after ſowing, and ſometimes longer, before the carrots appear: this is the principal advantage, beſides the difference of expence, that turnips have over them, for the latter are not ſown till about Midſummer, and coming quicker to the hoe, get the better of the weeds more eaſily; for weeds do not grow near ſo faſt about Midſummer, as in the ſpring.

The carrots lying a longer time before they come up, and continuing afterwards a long time very weak, they are ſeven or eight weeks before they are fit for the hoe, and in the mean time afford the weeds an opportunity to get ſtrength, in a ſeaſon too, when unluckily they grow the faſteſt: Mr. Billing is therefore of opinion, that though it is neceſſary to ſow carrots before turnips, it is better to ſow them as late as you can with ſafety to the crop; for of his, thoſe ſown in April on the clover ſtubble came much the ſooneſt to the hoe, though later ſown.

The wheat and clover ſtubble were ploughed three times; the piece after turnips but twice; the firſt time ſhallow, the ſecond as deep as the ſtaple of the ground would permit; and on this ploughing the carrots were ſown.

As it would remove ſome of the objections to a carrot crop, and lighten much the expence of weeding, could they be ſown later; and as this might be done could the ſeed be made to come up ſooner, this ſenſible farmer imagines the ſeed might he ſteeped in ſomewhat that would forward its vegetation, and afterwards ſown, when dry enough to ſeparate.

Yet however expenſive the ſtrength of the weeds in a crop of carrots makes the hoeing of them, the crop itſelf is not apt to ſuffer, for though the young carrots are quite covered in a thicket of weeds before hoeing, and ſhould be buried in earth after the hoeing; yet they ſeem no way hurt if they get clear again, as they generally do in a fortnight after, if not cut off, or buried too deep, for want of ſkill in the labourer.

The Norfolk hoe is ſix inches wide. If the carrots chance to be tolerably clean, they may be hoed the firſt time for eight ſhillings per acre; but if the ground be full of weeds, occaſioned either by much rain, the foulneſs of the ground before ſowing, or the length of the time between the ſowing and hoeing, the firſt hoeing will amount to ten or twelve ſhillings per acre.

About ten days or a fortnight after hoeing, they ſhould be harrowed: this will diſplace the weeds, and prevent their growing again, which many of them will otherwiſe probably do, eſpecially if it be ſhowery weather; the harrowing does not hurt the carrot plants, but, on the contrary, does them much ſervice, by bringing freſh earth to them, as well as killing the weeds.

About three weeks after the harrowing, in caſe it has not perfectly cleared the ground of weeds, or in caſe new weeds come up, Mr. Billing hoes the carrots a ſecond time, which coſts about four or five ſhillings per acre, as the ground is more or leſs foul; and after this, if there ſtill remain any weeds, which will be the caſe if much rain falls during the time of the ſecond hoeing, a ſecond harrowing is beſtowed.

Where the weather has been favourable, and thoſe employed in hoeing have done their duty, the carrots once hoed and harrowed have been as clean as thoſe on which two hoeings, and as many harrowings have been beſtowed.

Mr. Billing next proceeds to inform us of the ſucceſs he had in the year 1763, on the ſeveral parcels of ground already deſcribed. His carrots proved beſt on the piece of two acres and a half that had been wheat, not dunged for the crop of wheat, but dunged for the crop of carrots, and on the half acre clover ſtubble dunged for the carrots.

Many of the carrots out of both pieces meaſured two feet in length, thoſe on the former from twelve to fourteen inches in circumference at the upper end, and thoſe of the latter from twelve to ſixteen; a difference of bulk owing, perhaps, both to the difference of ſoil, and the effect of former crops.

On the two acres and a half Mr. Billing computes he had from twenty-two to twenty-four loads per acre, and about fifty-five, or fifty-ſix cart loads on the whole: the half acre on clover ſtubble produced about twelve loads; the ſix acres and a half dunged for wheat, but not for carrots, produced from eighteen to twenty cart loads per acre, and in the whole about one hundred and four loads; the four acres not dunged for either wheat or carrots, produced from twelve to fourteen loads per acre, and in the whole fifty-two loads.

He had but an indifferent crop of turnips the ſucceeding year, on the ſeventeen acre piece, but had from ſixteen to eighteen cart-loads per acre of carrots on fourteen acres of it, but a very poor crop on the three remaining acres; ſo that he computes he might have on the

the ſeventeen acres after turnips not quite two hundred and ſeventy loads, which make, with the former, about five hundred and ten loads of carrots, equal in uſe and effect to near one thouſand loads of turnips, or three hundred loads of hay, as experience has convinced him from the various methods in which he had tried them.

Mr. Billing thinks it is not improbable that he might beſides loſe five or ſix loads, which the poor people took, inſtead of a ſingle load they might have ſtole, had the land been cropped with turnips; but this loſs will be evidently much lightened, ſhould the growth of carrots become general in the country.

The beſt method of drawing the carrots is with a four tined fork, with which a man breaks the ground ſix or eight inches deep, very carefully without injuring the carrots; and is followed by a little boy, who gathers the carrots, and throws them in heaps.

Our farmer began to draw his carrots for uſe about three weeks after Michaelmas; but as the cattle he intended to feed on them had never been uſed to ſo hard food, he thought it beſt to give them, at the ſame time, both cabbages and carrots, leſt they ſhould ſuffer by a diſtaſte at the beginning.

He had about forty load of cabbages growing on one half acre, equal in uſe, as appeared on trial, to about ſeventeen or eighteen loads of carrots. He obſerved, that cattle of every ſort naturally eat the cabbages as readily as they would have done turnips; and ſoon after having gradually learnt to eat carrots, began to prefer them. Both the cabbages and carrots, and afterwards the latter with turnips, were brought from a place where they grew, to a paſture cloſe; and, without any other preparation than ſhaking off the dirt, they were diſperſed on the ground for the cattle to feed on promiſcuouſly.

From the experience Mr. Billing has had in fattening cattle on turnips in houſes or ſtalls, he is perſuaded that by this means the carrots might have been made to go a great deal further; but beſides the great trouble attending this method, eſpecially if the number of beaſts be great, and the hazard of beaſts foundering in the way to London, an accident that often happens to ſtall fed cattle, and that the benefit of their ſtale is loſt to the ground, he is convinced the beef is not ſo good, though perhaps more ſightly.

The firſt flock he began to feed in this manner conſiſted of twelve neat beaſts, and forty-nine ſhearing weathers, or thoſe not quite two years old: ten of the former were Norfolk bred ſteers, and began to feed on the firſt carrots he drew: at the ſame time he put on a cow, and a heifer three years old. At old Martinmas Mr. Billing bought ſeventeen Scotch bullocks, which, with a cow from his dairy, made up the number thirty; and ſoon after he increaſed this number to thirty-three, by adding three more from his dairy.

It is, however to be obſerved, that when the cabbages were ſpent, he allowed a load of turnips each day for ſome time for this flock of cattle, which, with three loads of carrots, was a ſufficient proviſion for them. This enabled him to determine, that one load of carrots is nearly equal to two of turnips; for if the cattle had been fed on turnips only, it would have coſt him little leſs than ſeven loads, computing on the experience of many years fattening cattle with turnips; yet he declares he never knew cattle thrive faſter.

Nine of the ſteers were ſold fat in Smithfield on the ſeventeenth of February, and weighed about forty Norfolk ſtone, that is, ſeventy London ſtone, each. Another ſteer and cow were killed in the country, the latter at Weaſenham town, and which died very fat, about the ſame time: the Scotch were ſold at St. Ives about the beginning of May: the ſteers ſold in Smithfield for about ſeven pounds fifteen ſhillings each.

Our farmer being told the market was then low there, ſold all the Scotch, except one, at St. Ives, where they fetched him about ſeven guineas each.

The former coſt about four pounds ten ſhillings each; the latter three pounds fifteen. The other Scotch he ſent to London, where, though it weighed but a little above ſixty ſtone, it ſold for eight pounds, and was ſaid to be ſome of the fatteſt beef killed in London that winter, as Mr. Billing was informed by Mr. Brownſworth the ſaleſman: the others were not inferior.

The forty-eight weathers were ſold at St. Ives in the month of May, at about fifteen ſhillings each.

Theſe thirty-three beaſts, and forty-eight ſheep, brought Mr. Billing, according to his computation, about one hundred and twenty pounds profit; out of which deducting one tenth for the ſhare the cabbages and turnips had in fattening them, which is rather too much, eſpecially as the cattle ſoon began to leave the turnips, there remains one hundred and eight pounds to be carried to the account of the carrots.

The large quantity of carrots our induſtrious farmer had growing gave him alſo an opportunity of trying their uſe in feeding dairy cows, ſheep, horſes, and hogs.

In the month of April he found he ſhould have nine or ten acres to ſpare, beyond what was neceſſary to complete the fattening his bullocks. This happened too at a time when his turnips, as well as thoſe of his neighbours, began to decay, and enabled him to ſupply that defect, to which the Norfolk farmers are very ſubject in the ſpring of the year, and which no method of managing their turnips ever exempted them from, when the weather is wet and froſty by turns; and from this decay the carrots ſeem protected by their hardineſs. From this time he fed his whole dairy of thirty-five cows, and his flock of twenty-one ſcore of ſheep, on carrots.

At the ſame time he thought of a method of getting the carrots out of the ground with more eaſe and expedition than he had done before, which was of great uſe when he had other occaſions for his ſervants; beſides which it alſo prepared the land better for the enſuing crop.

They were ploughed up with a narrow-ſhared wheel plough; going ſlow, the ſhare opened the earth, and cut very few of the carrots; thoſe few being only ſuch as chanced to meet the very point of the ſhare.

The plat or earth-board, turned moſt of the carrots out of the ground, and, by harrowing afterwards, were moſt of them quite cleared from the earth. Though the roots extended a good way into the ground, and below the pan, he did not think it neceſſary to plough ſo deep, and conſequently the land ſuffered no damage, which otherwiſe it might have done, as ſome few of the carrots inſtead of being turned out, were buried: it is alſo neceſſary to plough the land and harrow it a ſecond time; but though this ſhould be at an interval of a month, the buried roots will take no harm.

Mr. Billing turned his dairy cows and flock of ſheep on this

this land after the ploughing, without any further trouble or preparation, and had all the reaſon in the world to be pleaſed with the event; both took readily to eating the carrots, though he thinks the cows more ſo than the ſheep.

The former not only gave more milk than is uſual at that time of the year, but many continued to give milk, which would with ſuch turnips as he had then to give them, have been nearly dry. The butter made was likewiſe much better than that of turnips; and both ſheep and lambs did much better than he ever remembers them to have done at this ſeaſon of the year: beſides this, the land was evidently very much improved from the ſtale of the cattle, of which he plainly perceived the benefit in the enſuing crop.

It is proper to obſerve, that in this method, ſome few of the carrots continued buried, even after a ſecond ploughing; but theſe were turned out upon a third ploughing, when barley was ſown, and were clean eaten up by a flock of ſheep, without any injury to the new ſown barley.

In this manner the cows and ſheep were fed for three weeks, which Mr. Billing values at about twenty pounds; and, conſidering how he might have ſuffered, had he wanted turnips, and not been able to ſupply that want with carrots, he thinks, he might value his feed at a great deal more.

In November 1763, he began to feed ſixteen horſes, which did all his farming work, with carrots: they had neither hay nor corn, except his team that carried his corn to Brancaſter, a ſea-port, at fifteen miles diſtance: to this team he allowed a buſhel of oats a day to the whole team: the reſt had nothing beſides carrots, except peaſe-ſtraw and chaff, until the ſowing barley. In April he increaſed their work ſo much, that he thought it neceſſary to give them a few oats; but they continued to ſubſiſt chiefly on carrots, until they were turned to graſs, the latter end of May.

Mr. Billing declares he never knew his horſes in better order, or do their work better; and they were ſo fond of carrots, that he frequently found, that when the team mentioned before was ſo fatigued, that they refuſed to eat their corn, they would eat it when mixed with the carrots chopped.

It may be proper to obſerve, that he always chopped off the heads and tails of the carrots he gave his horſes, and ſometimes gave them another cut. Though he could not find it was neceſſary, he maſhed them alſo for his horſes, none of which trouble he found at all requiſite or even uſeful for other beaſts: the gathering and removing the carrots, and diſperſing them about the paſture-land where he fed his cattle, were ſufficient.

Mr. Billing gave the ſixteen horſes two loads of carrots every week; and theſe two loads, he computes, ſaved him more than a load of hay; which, at twenty-five ſhillings a load, amounted to thirty-five pounds.

To this might be added, the benefit received by the ſwine, to which he threw all the tops and tails of the carrots uſed for the horſes; and they throve exceedingly, and were ſo fond of them, that he never could find that any dirt which might ſtick to them, prevented their eating them: but as the principal part of the food of the ſwine was milk at firſt, and afterwards peaſe, our farmer has not ſet any value on this part of his profit; the total of what he has eſtimated is on the other articles, amounting to one hundred and ſixty-three pounds.

Of the thirty acres and a half, four were ſown in the year 1764, with oats, all the reſt with barley: the four acres were part of the land where he ploughed up the carrots; the reſt of this piece was ſown with barley; both produced a prodigious crop, not leſs than three loads of corn in the ſtraw, per acre: on the reſt of the land his crop was leſs bulky, and ſhorter, yet very good, perhaps not leſs in the quantity of grain than the other. And here it may not be improper to mention, that when in a former year, he had ſown the two ends of a large cloſe with carrots, without dung, and the middle with turnips, for which the land was well dunged, yet, when the whole encloſure was, the next year, ſown with barley, that after the carrots was the beſt.

Another recommendation of carrots is, that our intelligent farmer finds them a more certain crop, both for growth and duration, than turnips: the latter are exceedingly apt to fail, as well as rot, towards the ſpring, when moſt wanted. Perhaps the former is, in ſome meaſure, owing to the lands in Norfolk being, as the farmers expreſs it, ſurfeited with turnips, to which they have been ſo long accuſtomed. But however this be, there are many reaſons for chuſing both, that if one fail, we may rely, for ſo neceſſary a winter proviſion, on the other.

This candid farmer thinks he ought not, however, to conceal, that at the firſt beginning of a new ſort of huſbandry, many difficulties ſtand in the way: the expence is very heavy, much beyond the expence of turnips, and is, perhaps, increaſed by the aukwardneſs of labouring men and ſervants, who are both ignorant and perverſe about moſt new employments: beſides this, the cleaning of carrots from weeds is much more neceſſary than of turnips, and yet goes on much ſlower, ſo as ſometimes hardly to be completed: and, moreover, if a long continued froſt ſhould happen, it will be very difficult to get carrots out of the ground (indeed the turnips in this caſe are apt to ſpoil); but this inconvenience may, in ſome meaſure, be prevented, by drawing the carrots before the froſt; though this will be attended with difficulty when the quantity amounts to fifty or a hundred loads.

Such is the account given by Mr. Billing, with regard to the culture and uſe of carrots, for the feeding of cattle. And as theſe experiments were made ſo much at large, the farmer may, without heſitation, adopt this method; and if his ſoil is adapted to the growth of carrots, he need not doubt of greatly increaſing his annual profit. That they are wholſome feed for cattle has been long known; but that ſuch advantages reſulted from their uſe as Mr. Billing relates, few farmers could have imagined.

Wild CARROT, *Bird's-neſt*, or *Bee's-neſt*, the name of a biennial weed common in paſture grounds. It greatly reſembles the cultivated carrot, of which indeed it is only a ſpecies. The wild ſort however differs from the cultivated in its roots, which are ſmall and ſticky. In both ſorts, after they have done flowering, the umbels contract themſelves into the ſhape of a bird's neſt.

CAR SICK, a term uſed in ſome of the northern counties to ſignify the cart rut, or gutter made by the wheel of a cart or waggon.

CART, a vehicle mounted upon two wheels, and drawn by one or more horſes.

The chief difficulty in the conſtruction of wheel carriages,

riages, conſiſts in properly adapting the wheels and axle, which ought to be done in ſuch a manner, that the carriage may move with the leaſt force poſſible. *See the article* WAGGON.

CART-LODGE, a ſmall out-houſe for ſheltering carts, waggons, &c. from the weather.

Farmers ſhould be very careful to place their waggons, carts, &c. under proper ſhelter, when out of uſe, as they will laſt twice as long by this means, as they would if expoſed in the yard to all weathers; for as they are thus ſometimes wet, and ſometimes dry, they ſoon rot, and become unfit for uſe.

CART-LADDER, a kind of rack, placed occaſionally at the tail of a cart or waggon, to make it hold the larger quantity of hay, ſtraw, &c.

CART-RAKE, the cart track, or furrow made by the wheels of a cart or waggon.

CART-RUT, the ſame with cart-rake. *See the preceding article.*

CARTWRIGHT, a perſon whoſe buſineſs it is to make carts, waggons, &c. generally called a wheelwright.

CARUE, or KERUE, ſour. Thus to carue, ſignifies to grow ſour, and is generally applied to cream.

CARUNCLE *of the eye*, the fleſhy ſubſtance in the inner corner of a horſe's eye, next the noſe.

CASINGS, or COW-BLAKES, dried cows dung, uſed in ſeveral parts for fewel.

CAST, a flight of birds, inſects, &c. Thus a caſt of bees, ſignifies a ſwarm or flight of bees.

CATCH-LAND, a name given to ſuch land as is not certainly known to which pariſh it belongs; and therefore the miniſter, who firſt gets the tithes of it, enjoys it for that year.

CATERPILLAR, a general name for all inſects of the butterfly kind, while they continue in their reptile or worm ſtate.

It is well known, that all winged inſects paſs through a reptile ſtate, before they arrive at perfection. This great change from a worm to a fly, or butterfly, was formerly eſteemed a real metamorphoſis, or change of one animal into another; but later diſcoveries have put it beyond all doubt, that the embrio butterfly, with all the lineaments of his parent, is contained within the external caſes, or coverings of the caterpillar. When the included animal has acquired a ſufficient degree of ſtrength, theſe coverings are thrown off, and it appears in its genuine form of a fly, or butterfly. It muſt, however, be obſerved, that before the creature can free itſelf from theſe coverings, it muſt paſs through a ſtate of reſt, called by naturaliſts nymph, or chryſalis ſtate.

Mr. Hitt obſerves, that there are two ſorts of caterpillars, at leaſt thoſe of two colours, which feed upon fruit-trees, the one black, and the other green. The black generally make their appearance in March, if the ſeaſon be dry, upon the pear, apple, and ſeveral other trees.

Sometimes great numbers of them are contained in a ſort of kel, or web, and, if they are to be come at, ſhould be taken off; for otherwiſe they will diſperſe themſelves to all parts of the tree, and there feed upon the bloſſoms, leaves, or their buds, before they are unfolded. After they have lived ſome time in this active ſtate, they generally conceal themſelves in a bunch of leaves, or in a cavity of the rind of a tree, where many of their eggs are hatched the ſame ſummer, and become very deſtructive. There is alſo reaſon to think, that ſome of their eggs are preſerved in thoſe places during the winter, as many of them, and ſome kindled or animated, have been found in old nail holes, and under pieces of dead bark, during the month of February.

The walk ſhould therefore be well waſhed, and the dwarfs and ſtandard trees well dreſſed and cleanſed at that ſeaſon.

The green caterpillars, which may, perhaps, be the ſame with the former at their firſt appearance, till their colour is gradually changed by living wholly on green food, are never ſeen ſo early in the ſpring as the former; but are very prejudicial to both the young branches and fruit of the apricot, cherry, plum, apple, pear, currant, gooſeberry, &c.

They are never ſeen in great numbers together incloſed in a kel or web; but are generally found ſingle, wrapt up in the extremity of a new made branch of the abovementioned trees, or in a bunch of bloſſoms of an apple, pear, or cherry-tree, and ſometimes on an apricot, with a leaf to cover them. Part of their bad effects may be prevented in wall-trees, or dwarfs, whoſe branches are within reach. If they be at the extremity of a branch, it will appear in a round knob, and they generally eat off the part they had wrapt together, which ſpoils the branch the next year. When they have incloſed themſelves in a bunch of bloſſoms, or young fruit, then they prove very deſtructive, by generally eating into all they had joined together, which cauſes much fruit to drop off ſoon after, and others when they are more grown.

Some of thoſe which are but ſlightly eat, will continue upon the tree till the time of gathering; but they never make good fruit, being generally ill taſted, and many times have a white grub within them.

When the caterpillars are firſt perceived upon the wall or dwarf trees, whether before or after they are wrapt up, a brine ſhould be prepared, and the trees ſwept all over with a bruſh or beſom dipt in it. This will deſtroy many of the inſects, by beating ſome off, and killing others. This work ſhould be often repeated, if there be a neceſſity for it, as there generally is in dry ſeaſons. Perhaps a ſmall engine would be the propereſt and moſt effectual inſtrument for this work.

But gentlemen, who have leiſure ſufficient, may eaſily preſerve their fruit-trees from the ravages of caterpillars, by carefully inſpecting them every day in the ſpring; for it will eaſily be ſeen when a bunch of bloſſom-leaves, or young fruit, are joined together by a caterpillar; and, on the firſt diſcovery, the leaves are to be ſeparated by the hand, and the caterpillars killed; this will ſave a young branch or bunch of fruit, which would otherwiſe have been certainly deſtroyed. Whoever perſeveres in this work will never have much of their fruit deſtroyed by ſuch inſects, which experience has ſufficiently demonſtrated to be more deſtructive to the fruit, than any other cauſes that happens in the ſpring, though many will attribute the ſcarcity of fruit to blaſts or lightnings, or to the branches being ſun-burnt, which are the common conſtructions put upon the effects of theſe inſects.

When ſtandard trees are properly ordered with cutting and dreſſing, they will not be much ſubject to be infected with caterpillars; for by taking off the old rind, and cleaning the cankered parts of thoſe trees, many of the inſects are deſtroyed, together with their eggs concealed

in thoſe places; and by keeping the branches thin and open, they are more eaſily ſhaken off by the winds. *Hitt on Fruit-Trees, page* 265.

Caterpillars not only deſtroy the leaves and bloſſoms of fruit-trees, but they alſo deſtroy cabbages, and other productions of the garden; and are generally the effect of great drought.

To prevent their numerous increaſe on trees, gather them off in winter, taking away the prickets which cleave to the branches, and burn them; but if they get on cauliflowers or cabbages, take ſome ſalt water, or ſtrong brine, and water the plants with it, and it will kill the inſects: the ſame effect may be produced by taking ſome of the caterpillars themſelves, bruiſing them with garlic, and infuſing the mixture in water; or you may ſmoke them with wiſps of dry ſtraw in March, juſt as the bud begins to open.

In the ſummer while they are yet young, when, either through the coldneſs of the night, or ſome humidity, they are aſſembled together on heaps, you may take and deſtroy them; or you may waſh your trees with water, in which wormwood, tobacco-ſtalks, and coloquintida have been diſſolved; or take lime duſt, and when the wind is high, and the trees wet, ſprinkle the duſt, ſo that the wind may blow it on the trees. *Mortimer's Huſbandry vol.* I. *p.* 325.

CATKINS, a name given to ſuch flowers as have an aggregate of ſummits hanging down, in the ſhape of a rope, or cat's tail.

CAT's-FOOT, a name given in ſome countries to ground-ivy.

CAT's-TAIL, a round ſubſtance growing upon nut-trees.

CATTLE, a general name for beaſts of paſture, that are neither wild nor domeſtic; but generally confined to thoſe of the ox kind.

Cattle are known to be very advantageous to the breeders of them; and therefore thoſe in middling fortune would do well to apply ſome part of their time and farms to this uſeful work: but people in theſe circumſtances, finding it impracticable to make large profits, too often reject, with diſdain, the ſmall advantages continually in their power. In vain the wiſe man informs them, that whoever neglects ſmall profits will daily decay; in vain reaſon dictates, that from a ſmall ſtock, they muſt be contented with ſmall gain; but that a great number of ſmall profits, which it is eaſy to multiply by labour, becomes in a ſhort time an object of conſideration.

It muſt not however be imagined, that in order to derive a conſiderable advantage from cattle, it will be ſufficient to have a great number, and to give them the neceſſary fodder: there are many other circumſtances to be attended to, without which it would be in vain to flatter ourſelves with the expectation of riches. They are often kept in too narrow a cow-houſe, from whence many inconveniencies ariſe. Sometimes they fight, and wound one another. The moſt voracious ſtarve their neighbours, from whom they carry off all the fodder within their reach; and the injured cows decay inſenſibly, become languid, or give little milk. In ſummer the heat incommodes them, a circumſtance which makes them grow lean, and diminiſhes the quantity of their milk. Care muſt therefore be taken that they have ſufficient room in their ſtalls; that they be cool in ſummer, and warm in winter. At all ſeaſons let them be dry, for that is a material point. Even in ſummer, humidity is diſagreeable to them, and in winter it chills them. To prevent this double inconvenience, it will be proper to pave the cow-houſes on a gentle deſcent, and to dig a pit to collect all water and ſtale. By this means the cattle will lye always dry, and the ſtale be collected for good purpoſes. Horned cattle ſometimes contract a habit of licking one another; and that injures ſo much, that a butcher who perceives it, will give leſs money for them than for others. They are cured of this habit, by rubbing the places they have licked with cow dung, the bitterneſs of which prevents them from purſuing it.

We ſhall inſiſt on the advantages attending the breeding of young cattle, whatever trouble it may coſt; becauſe there is no prudent countryman who is not fully perſuaded they are real. To buy what he may have of his own growth is to a farmer no acquiſition, but a diſſipation; becauſe the land produces no money, which is only to be obtained by the ſale of commodities, and very often the purchaſe of ſome goods deſtroys all the profit reſulting from the ſale of others. It ought, therefore, to be an inviolable maxim, eſpecially with thoſe in narrow circumſtances, to ſpare no pains in improving their ſtock, not making ſmall eſtimation of what has coſt them no money, but frugal as if they had bought it. By this means, if we accept unforeſeen accidents, which can never be prevented, they will find wealth flow in upon them annually, though ſlowly, and lay the foundation of a ſolid fortune. *Journal Oeconomique.*

Fattening and feeding CATTLE. Cattle are bought in to fat at ſpring, and about Michaelmas. Thoſe you buy in at ſpring will be fat in July, Auguſt, or September, according as they are forward, and you have keeping for them; and thoſe which you buy in Auguſt, September, or October, muſt be either to ſell in winter or in ſpring, and muſt be forward in fleſh to be improved the beginning of winter, and only kept up in fleſh during the hard time of winter, either with burnet hay, turnips, carrots, &c. to be fit for a good market whenever it offers; or they muſt be young, lean, cattle, that may by their growth pay for their wintering, and to be fit to fat the next ſummer. Some upon ordinary land buy in young Welch heifers, which, if they prove with calf, they ſell in ſpring, with a calf by their ſide for the dairy; and thoſe that are not with calf they fatten: all which ways turn to good account, according as prices fall out; but moſt commonly all meat, either at Chriſtmas or in the ſpring, is one third part dearer than in ſummer: becauſe all have not the conveniency either of hay, turnips, &c. to fatten cattle with in winter; and it is but in a few places, eſpecially near London, which is the chief market for fat cattle, that hay can be afforded to fatten them with; for they reckon an ox, that coſts about ſix pounds, will require about two loads of hay to keep him up all the winter.

For the wintering of cattle, you muſt about September turn out them you deſign to keep up for a winter or a ſpring market, and your cows, that give milk into your rowens, till either ſnow or a hard froſt comes on, as by that means they will need no fodder; but when either ſnow or froſt comes, you muſt give hay to ſuch cows as are near calving, or thoſe that have lately calved, or that give a great deal of milk, and alſo to your fattening cattle. This muſt be done every morning and evening, in proportion to the quantity of rowen you have upon the ground; for the more rowen you have, the leſs quantity

of hay will do, and even the ſour graſs which your cattle would not eat before, will, when the froſt hath taken it, become good, ſweet food for them, and what they will eat with pleaſure, if it be not covered ſo deep with ſnow, that they cannot come at it. But for your lean cattle, and thoſe that give but little milk, ſtraw will do well enough to fodder them with; only you muſt obſerve to give barley-ſtraw firſt, and the oat-ſtraw laſt, except you value your milk: if you do, give ſuch cows your oat-ſtraw, provided the quantity of milk they give doth not deſerve hay, or hay be ſcarce with you; for barley-ſtraw will quite dry up the little milk they have, though it is good food for dry cattle. But if your hay and carrots fail you, pour ſcalding hot water upon your malt-duſt, and, when near cold, give it the cows you deſign to continue the milk of, and it will cauſe them to give a great deal, though they eat ſtraw with it. A buſhel, which coſts about three-pence, will be ſufficient for a cow a week. But about London, where they have grains in plenty, they give them to their cows in winter, which makes them give a great deal of milk; but is apt to rot them, if given in too great quantities, and for too long a time.

When your rowen is quite eaten up, which will commonly be about February, you muſt houſe your milch-cows, which you give hay to all night in your cow-houſe, and your other cattle in your yard; for which uſe you ſhould have two yards; one for your cattle which eat ſtraw, with racks and other conveniences to fodder them in; obſerving to feed them often, and not to give them too much at a time; becauſe when they have blown upon it, they will not eat it; both your yards ought to be well ſheltered, and made as dry as poſſible, and a good deal of ſtraw given them to lye dry and warm in, which is a very great advantage to them, and will greatly increaſe the quantity of your dung.

As to the buying of fat cattle, milch-cows, or lean cattle, experience, and the advice of ſuch perſons as underſtand them are the beſt inſtructors.

For the feeding of land, you may do it with beaſts and horſes together, or with beaſts firſt, and horſes afterwards; and after both put in ſheep. But let not your graſs be too rank before you feed it; for if you do it will be ſour, and your cattle will eat the tops only, ſo that the other part will lie untouched, and rot upon the ground, as hardly any beaſt will eat ſour graſs, till the froſt hath taken it, except Welch heifers. Obſerve alſo, where you have incloſures, to be often changing of your cattle from one paſture to another; for by that means you will give your land an opportunity of getting a freſh head, freſh graſs being a great help to the feeding of cattle. *Mortimer's Huſbandry, vol.* I. *p.* 231.

Cattle are frequently well fed in the winter with rye-ſtraw, mixed with a little hay; with the ſtraw or halm of buck wheat; with the leaves of white beet; with turnips, the turnip-cabbage, carrots, cabbages, burnet, and the bruiſed tops of furze; as may be ſeen under each article. They are alſo well fed and fatted with the cakes of lin-ſeed and rape-ſeed, or cole-ſeed. *See the articles* COLE-SEED *and* LIN-SEED.

It is really ſurprizing that though plants have been conſtantly obvious to the eyes of every man, nothing has been delivered down to us in any book, concerning the kinds of plants proper for the different kinds of cattle; the conſequence of which inattention frequently is, that the farmer, by not diſtinguiſhing and ſelecting the ſeeds of proper graſſes, fills his paſtures with weeds, or, which is here equivalent to them, with bad graſſes, unfit for the nouriſhment of the animal he intends to rear.

The illuſtrious Linnæus in his journey through Dalecarlia in the year 1734, made the firſt attempt to lay down rules for the farmer's direction in this intereſting ſubject. In his journey he obſerved, that the horſes eaſily diſtinguiſhed wholeſome from noxious food; for, being very hungry, they devoured all ſorts of plants, except the meadow-ſweet, valerian, lilly of the valley, angelica, looſe-ſtrife, marſh-cinquefoil, crane's-bill, hellebore, monkſhood, and ſeveral ſhrubs. This gave him a hint to recommend to the curious to apply themſelves to examine what plants ſuch animals as live on vegetables will not touch.

The ingenious author of the Swediſh Pan, in order to encourage inquiries of this kind, very properly obſerves, that we admire the wiſdom of the Creator, which has made ſome vegetables abſolutely diſagreeable to ſome animals, while they are agreeable to others; and plants, which are poiſonous to ſome, are wholeſome to others. This did not happen by chance; it was ordained for wiſe purpoſes: for if the Author of nature had made all plants equally grateful to all kinds of quadrupeds, it muſt neceſſarily have happened, that one ſpecies of them having remarkably increaſed, another ſpecies muſt have periſhed by hunger, becauſe it would have got into better paſture. In like manner we find it contrived in relation to the plants themſelves, which do not all grow in the ſame country and climate; but every plant has its place, in which it grows more abundantly than elſewhere. From hence we may obſerve, that thoſe animals which live chiefly upon particular plants, abound moſt in certain places. Thus one animal leaves that which is poiſonous to itſelf, for another animal, which feeds upon it deliciouſly. Long-leaved water hemlock will kill a cow, whereas the goat browſes on it greedily. Monkſhood kills a goat, but will not hurt a horſe. Parſley is deadly to ſmall birds, while ſheep, hares, rabbits, and ſwine eat it ſafely; and pepper is mortal to ſwine, and wholeſome to poultry. Hunger will often drive animals to feed upon plants which nature never intended for them: but after this has happened once, they become more cautious for the future.

Perhaps many of the terrible diſeaſes to which cattle are ſubject, and which has ſwept away innumerable multitudes, may, in part at leaſt, be owing to the mixture of noxious plants among their food. The great Linnæus was of this opinion; and the following paſſage in the writings of that admired naturaliſt is too intereſting to be omitted in a work of this kind:

"When I arrived, ſays he, at Tornea, the inhabitants complained of a terrible diſeaſe than raging among the horned cattle, which died by hundreds, ſoon after their being let into the paſtures in the ſpring. They deſired I would conſider this affair, and give them my advice what was to be done, in order to put a ſtop to this evil. After a proper examination, I thought the following circumſtances worth obſerving:

"1. That the cattle died as ſoon as they left off winter fodder, and returned to grazing.

"2. That the diſeaſe diminiſhed as the ſummer came on; at which time, as well as in the autumn, few died.

"3. That this diſtemper was propagated irregularly, and not by contagion.

"4. That

"4. That in the ſpring, the cows were driven into a meadow near the city, and that they chiefly died there.

"5. That the ſymptoms varied much, yet agreed in this; that the cattle, in grazing indiſcriminately on all ſorts of herbs, had their bellies ſwelled, were ſeized with convulſions, and in a few days expired with dreadful bellowings.

"6. That no man dared to flea the recent carcaſſes; as they found by experience, that not only the hands of ſuch as attempted it, but their faces too, had been inflamed and mortified, and that death had enſued.

"7. The people enquired of me, whether there were any kind of poiſonous ſpiders in that meadow; or whether the water, which had a yellowiſh tint, was not noxious.

"8. That it was not a murrain was clear, becauſe the diſtemper was not contagious, and becauſe that diſtemper is not peculiar to the ſpring. I ſaw no ſpiders but what are common all over Sweden; and as to the water, the ſediment at the bottom, which cauſed the yellowneſs, was nothing but what came from iron.

"9. I was hardly got out of the boat which carried me over the river into the meadow, before I gueſſed the real cauſe of the diſeaſe; for I there beheld the long-leaved water hemlock. My reaſons for gueſſing this were the following:

"10. Becauſe in that meadow where the cattle firſt fell ill, this poiſonous plant grows in great plenty, chiefly near the banks of the river. In other places it was ſcarce.

"11. The leaſt attention will convince us, that brutes ſhun whatever is hurtful to them, and diſtinguiſh poiſonous plants from thoſe which are ſalutary, by natural inſtinct; ſo that this plant is not eaten by them in the ſummer and autumn, which is the reaſon that few cattle died in theſe ſeaſons; thoſe only which eat of it by accident, or were driven to it by extreme hunger.

"12. But when they are let into the paſtures in the ſpring, partly from their greedineſs after the herbs, and partly from the hunger they had undergone during the winter, they devour every green thing that comes in their way. It alſo happens that herbs, at this ſeaſon, are ſmall, and ſcarcely ſupply food in ſufficient quantity. They are beſides more juicy, and covered with water, and ſmell leſs ſtrong; ſo that what is noxious is not eaſily diſcerned from what is wholeſome. I obſerved likewiſe, that the radical leaves were always bitter, and the others not, which confirms what I have juſt ſaid.

"13. I ſaw this plant in an adjoining meadow mowed along with graſs for winter fodder; and therefore it is no wonder, that ſome cattle, though but a few, ſhould die of it in the winter.

"14. After I left Tornea, I ſaw no more of this plant, till I came to the vaſt meadows near Limmingen, where it appeared along the ſides of the road; and when I got into the town I heard of the ſame complaints as at Tornea, of the annual loſs of cattle, with the ſame circumſtances.

"15. It would therefore be worth while to eradicate carefully theſe plants, which might eaſily be done, as they grow on marſhy grounds, and generally by the ſides of pools and rivers. But if this cannot be performed, the cattle ſhould not be ſuffered to go into ſuch places, at leaſt during the ſpring: for I am perſuaded that later in the year they can diſtinguiſh this plant by the ſmell alone." *Lin. Flora Lapponica.*

Were experiments carefully and judiciouſly made on the above beneficial plan, we ſhould ſoon know with certainty what ſpecies of animals any paſture affords the beſt nouriſhment for. We ſee, for example, heifers fall away in encloſures, where the meadow-ſweet grows in abundance, and covers the ground ſo that they can hardly make their way through it: while the country people, imagining that the paſture is too rich for them, are quite amazed, and never dream that the meadow-ſweet affords them no nouriſhment: whereas the goat, which ſtands bleating on the other ſide of the hedge, is not ſuffered to go in, though he longs to be browzing upon this plant, which is to him a moſt delicate and nouriſhing food. Long experience has taught us, that ſheep take up poiſon in marſhy grounds, though no one till lately knew what the particular poiſon was: yet the ſpiderwort, the mouſe-ear ſcorpion-graſs, the mercury, the ſun-dew, the hairy wood-graſs, the leſſer ſpearwort, and the butterwort, have evidently ſuſpicious marks.

Hence we ſee, that what makes low grounds ſo noxious to ſheep is not wholly the moiſture, but the plants which grow there; for it is remarked by ſhepherds, that the great danger to ſheep is immediately after a freſh ſpring of graſs, when it is natural to think they lick up the young and tender ſhoots of poiſonous plants along with their proper food, not being then able to diſtinguiſh the one from the other.

From obſervations of this kind the huſbandman may form a right judgment of his meadows, and turn into each the animals beſt adapted to the nature of the paſture.

"The induſtrious farmer, ſays the author of the Swediſh Pan, may judge from hence, when he ſows his meadows with hay ſeeds for paſture, that it is not indifferent what kind of ſeeds he chooſes, as the vulgar inadvertently think: for ſome are fit for horſes, other for cows, &c. Horſes are nicer in chooſing than any of our cattle. Plants, whoſe ſeeds grow in pods, are particularly reliſhed by them. Goats feed upon a greater variety of plants than any other cattle; but then they chiefly hunt after the extremities and flowers. Sheep, on the contrary, paſs by the flowers, and eat the leaves. And again, different animals have different diſpoſitions as to grazing more or leſs near the ground. The huſbandman, who underſtands theſe things, and who, in conſequence thereof, knows how to lay out his lands, ſo as to aſſign to each ſort of cattle its proper food, will neceſſarily have his flocks and herds healthier and fatter, than he who is unacquainted with theſe principles. The good manager will alſo obſerve the ſame precautions in the making of his hay: for although many herbs are eaten when dry, which would be refuſed while green, it does not from thence follow, that they yield good nouriſhment. Much might be added concerning the propenſity of cattle to this or that plant: for example, that ſheep delight above all things in the feſcue graſs, and grow fatter upon it, than on any other kind of graſs; that goats preſer certain plants, but, being led by an inſtinct peculiar to themſelves, they ſearch more after variety, and do not willingly ſtick long to any one kind of food; that geeſe are particularly fond of the ſeeds of feſcue graſs; that ſwine hunt greedily after the roots of bullruſh, while they are freſh, but

will not touch them when they are dry." *N. Haſſelgren. Acad. Upſalenſ. Academ. Suec. tom.* II.

If a farmer, ſays the intelligent Mr. Liſle, intends to graze cattle in a hill country farm, theſe three things are eſpecially to be regarded; firſt, to raiſe a good quantity of French graſs for hay and aftermaths. Secondly, to turn a good quantity of hill country meadow into rich paſture, by ſeeding it, dunging it, and laying on it other manure, to make it fit for raiſing the bullock or heifer in the ſpring, when he comes firſt from hay into graſs-leaſe, and to receive him with a vigorous aftermath, when other graſſes, as clovers, and French graſs aftermath, goes off. Thirdly, to have hovels in your bartons, incloſed with cloſe court-walls, to ſhelter your cattle in the winter from wind and rain. All theſe three things are neceſſary and uniform, correſponding with one another; without them, grazing muſt be carried on very defectively, and to little profit, by the hill country farmer.

By the methods here preſcribed, in order to the fattening of cattle, plenty of French graſs hay will enable the grazier to purchaſe barren beaſts before the ſpring graſs comes, when it is moſt likely they will be cheap, and may be bought to the beſt advantage, allowing the value of the hay they may eat in conſideration with the purchaſe; and if by winter-hayning ſome meadow ground (after it has been kept high in heart, by feeding and ſoiling it) you can early in the ſpring, by April, or ſooner, have a bite to take off ſuch grazing beaſts from hay to graſs, it will be very advantageous before clovers can be ready, which are ſeldom ſo, in the hill country, till a week or a fortnight in May; and by hayning up ſuch meads for an aftermath, which towards the end of ſummer are in very good heart, you will ſupport your bullock, and carry him on when the ſpirit of other graſſes fail. Then ſuch cattle as are unfiniſhed being brought to French graſs hay, and tied up under hovels or coverings, and within court-walls, will proceed in thriving by being ſecured from the wind and rain, and the tedious hill country rimes, that often continue whole winter days, all which makes cattle brought from graſs to pitch, and maſhes them out. Beſides, if you have not plenty of French graſs hay, you cannot make the beſt of a milch-cow that warps, or of a cow that towards the latter end of winter you may perceive proves barren, or of a fat cow that caſts her calf before you kill her. The neceſſity of French graſs hay only, and not of clover hay, is mentioned here, becauſe it is ſuppoſed that the hill country farmer, who provides ſtore of French graſs hay, will be wiſe enough not to mow his clover to feed them, in order to improve his lands; for the hill country farmers have generally ſo much land for their money, that all they can do is little enough to keep their arable land in ſuch heart as it ought to be in for their profit.

If the foregoing cautions are not obſerved, the ill conſequences that will follow muſt be ſuch as theſe: if the firſt of the three foregoing cautions be diſregarded, your cattle cannot at any time of the year be made fat, as they ought to be, and then you muſt be under the neceſſity of ſelling them half fat, of which neceſſity the buyer never fails to take the advantage; and ſell them you muſt, notwithſtanding there be ever ſo fair a proſpect of prices riſing in a month or two; and you will commonly find, that you have nothing for the meat they have eat whilſt they have been fattening. In the ſecond place, we will ſuppoſe that very few will be ſo unwiſe, as to begin to fat a beaſt in October with hay, and ſo to keep him upon hay during the winter: but we may reaſonably ſuppoſe, that warping beaſts, barren heifers, &c. may, and commonly are begun to be fatted with hay from Chriſtmas, in which caſe, though hay be plenty, yet if an early ſpring graſs be wanting, ſuch cattle muſt be kept on it at leaſt, till the middle of May; for till then, in the hill country, it will not give a beaſt a bite, and then commonly, where the maſter is at a loſs and diſappointed, the cattle evidently ſuffer before he can make the moſt of them, and, in this caſe, he will find a beaſt plainly pitch before he can find a purchaſer for him. Again, if early ſpring graſs be wanting, you cannot begin ſummer fattening of cattle, nor buy a barren heifer till towards the middle of May, and then they are commonly very dear: and, in the hill country, from ſo late a beginning, the ſummer graſs will hardly fat a beaſt, the ground falling early off its ſtrength, being generally poor. And then, if you have not a quick growing aftermath treaſured up, by keeping ſuch ground as was formerly meadow in good heart for that purpoſe, it is plain you muſt again run into the firſt evil; and, if you have ſuch an aftermath, you may again often want hay in November and December, to finiſh ſummer fatted beaſts; ſo that plenty of hay is always neceſſary, &c. And, laſtly, though you have both hay and graſs, if you want winter ſhelter, the cattle muſt ſuffer.

All fattening cattle, whether lambs, ſheep, barren cows, or oxen, require a proportionable progreſſion from coarſer to better food, as they grow more and more into good fleſh; otherwiſe when half fat they will go back, and you will not without great difficulty raiſe them again, which will be a great loſs; nor will ſuch beef ſpend kindly.

A gentleman, who would make a good hill country grazier, ought, againſt the time he buys in his heifers, to take care to be provided with an overplus ſtock of middling good hay, or of winter vetches, or of barley ſtraw, and autumn graſs, mixed together, layer and layer of each. Be it what it will, it ought to be at leaſt better than barley ſtraw; for he is to ſuppoſe he has bought barren heifers, which have been kept all the winter upon ſtraw: if they have been kept better, for inſtance, on ſtraw and rowet, there is ſtill the greater reaſon for him to mend their keeping; and he is, from the time of buying, to conſider, that he ought to begin to raiſe them in fleſh; for the better caſe they are in when turned to ſpring graſs, they will take to fattening the kinder, and bear their firſt ſcouring the better. If he could turn them into the field, for an hour or two in the day, where there is a little rowet, it would do well, and to have change of the above dry meads would keep them the better to their ſtomachs.

Oxen are turned off to fattening at two ſeaſons of the year, which, in ſeveral reſpects, are very convenient. The firſt is about May-day, when the labour of the ox is pretty well over for the ſpring ſeaſon, the ſpring corn being then generally all ſown. The ſecond is the beginning of winter, namely, from the firſt of October, to the middle of November, when the wheat and winter vetches are generally all ſown, and the ploughman's hurry relaxes.

Oxen turned out at May-day will hardly get fat before

fore Chriſtmas, and if not turned out till June, will not be fat till March, April, or May; which again falls out very fortunately, becauſe from Chriſtmas till the latter end of May cow-beef is very ſcarce, and is generally ſupplied with ox-beef; but then it is obvious, when an ox gets half, or three quarters fat by or before winter, he muſt be ſupported and carried on by a great quantity of hay, and that very good, for the beaſt will then grow nice.

Thoſe that are turned from the plough in October and November, ordinary food will ſerve for ſome time; for ſhould you lay the beſt hay before ſuch an ox, then hungry and poor, he will devour more than the profit. The moſt you can propoſe by this method is to get him fat by July, inſtead of September or October; during all which interval of time, heifer-beef will be plenty, and ſink the price of ox-beef; ſo chargeable a method therefore will not quit coſts.

What the grazier ought to do in this caſe is to bring his ox eaſily and gently into good fleſh by a rowet; for which purpoſe he ought to have hayned up his grounds, and of which rowet he ſhould give him the worſt firſt, except it be of ſo ſour a kind as to want the correction of the winter froſts before he will eat it, of which kind ſtubble rowet commonly is, and in ſuch caſe that food muſt be reſerved till then, or rather for young beaſts and milch-cows. He ought to give him variety of dry meat along with his rowet, in which he ſhould conſult his tooth, by flinging before him, alternately, every ſort of good ſtraw, giving now and then a lock of winter vetches, or coarſe hay, but of every thing good in its kind, *i. e.* ſweet and well made; and thus the ox ought to be carried on throughout the winter. About the beginning of March he ought to have better hay; not only becauſe the rowet may be ſuppoſed to be all gone, but alſo becauſe the ox, mending in fleſh, grows nicer and will be weary of dry meat, through the tediouſneſs of being foddered ſo much with it during the winter; therefore his hay muſt be mended, for not proceeding is going back. Againſt April, if poſſible, a ſhort head of graſs ſhould be got for him in your paſture grounds for cow-cattle, by hayning the paſture in February, that he may have graſs along with his hay, as was before obſerved in the fattening of barren heifers; and againſt May a head of hop clover muſt be in readineſs, in the hill country, to receive him into his firſt full grazing; for it is not to be ſuppoſed that the meadows of the hill country, which according to this ſcheme are to be converted into paſture, can be fit before the firſt of June to entertain a grazing ox; and it is alſo to be noted, that in the hill country, in the month of May, hop-clover will not afford a good bite for an ox or cow, unleſs the autumnal bud be hayned, and preſerved by being fed by ſheep: in the month of May, if it ſhould prove a dry ſpring, the fattening oxen and cows muſt alſo have good hay given them, with their hop-clover, if it be ſhort.

Fattening in the hill country, eſpecially if you give your cattle hay in the winter, is more chargeable than in the vale; not only becauſe hay is dearer there, but alſo becauſe the winter ſeaſon begins a month ſooner, and continues a month later in the former than in the latter. The farmer in the hill country muſt likewiſe, by forcing nature as it were, provide rowet and ſeveral ſorts of graſſes in their due order, exactly accommodated to the ſeaſon of the year, beſides winter meat, &c. Whereas all may be procured by the latter in the natural courſe, with very little care and trouble.

It will be neceſſary to obſerve, that every hill country grazier goes to work without his tools, who does not lay down from fifty to an hundred acres of land proper for it, with French graſſes, not only on account of making up the deficiency of the meadows not laid down to paſture, being converted to other uſes, but alſo to anſwer many other demands. *Liſle's Obſervations in Huſbandry, vol.* II. *pag.* 18.

A ſtalled ox in the winter, if he be kept to hay only, will eat at leaſt a load every two months. *Ibid. p.* 5.

Fourteen pounds weight of hay is the conſtant allowance on the road to every fat beaſt that is drove to London; they that entertain cattle fling fourteen pounds of hay for each beaſt into the rack in the evening when they come into the inn, which is to ſerve alſo next morning for their breakfaſt; ſo that half a tod, or ſeven pounds of hay, is ſuppoſed ſufficient for a fat ox's bait at night, and the ſame in the morning. *Ibid. p.* 9.

For the manner of feeding and fattening cattle with cabbages, carrots, turnips, turnip-cabbages, &c. *See the articles* CABBAGE, CARROTS, &c.

CAUTERY, a name given to a red hot iron, uſed by farriers to deſtroy fungous fleſh, &c.

CAUTING-IRON, an iron with which farriers ſear thoſe parts of a horſe that require burning.

CELLS, the ſmall diviſions in honey-combs, which, geometers have obſerved, to be always regular hexagons.

CELLS, alſo denote the hollow places between the partitions in the pods, huſks, and other ſeed-veſſels of plants.

CENTAURY, the name of a weed abounding in arable lands, and generally called blue-bottle. *See* BLUE-BOTTLE.

CERES, a pagan deity, the inventor, or goddeſs of corn.

CERT-MONEY, a fine paid yearly by the reſidents of ſeveral manors to the lord thereof, and ſometimes to the hundred, for the certain keeping of the leet.

CHAFF, the huſks of corn that are ſeparated by thraſhing and winnowing. *See the articles* THRASHING *and* WINNOWING.

CHAFF alſo ſignifies the rind of corn: thus, barley that has a thick rind is ſaid to be thick chaffed.

CHAFF, likewiſe implies ſtraw, &c. cut ſmall, and given to horſes and other cattle, mixed with corn. *See the article* CUTTING-BOX.

CHALK, the Engliſh name of the white dry marl, with a duſky ſurface, found in hard maſſes.

Chalk is a laſting manure for ſuch lands as it agrees with, which are particularly thoſe of a cold ſour nature, and ſtiff untractable clays. Pliny tells us, it was the cuſtom of the ancient Britons to chalk their lands, by which they received a great and laſting improvement.

Farmers are apt not to diſtinguiſh ſufficiently between the different kinds of chalk. The hard, dry, and firm, is much the fitteſt for burning into lime; but the fat unctuous chalk is by far the beſt to be uſed crude. This oily, viſcous ſort of chalk, is uſed in many places inſtead of marl, to which it is nearly allied, though of an inferior quality. It it even called marl in the iſle of Wight, where their chalk is of a remarkably fat ſoapy nature; and they ſometimes lay twenty-five waggon-loads

loads of it upon one acre of ground. *Liſle's Huſbandry, vol.* I. *p.* 66.

A correſpondent of the editors of the Muſeum Ruſticum ſtrongly recommends chalk as a manure for clay lands; but adds, it ſhould be laid on rough, in large clods whereby the land will gradually receive the greater benefit by it. The ſalts in the air will penetrate, and crumble the clods; and the land, on which the chalk is laid, will ſoon be brought into a ſtate of fermentation, reduced and pulveriſed in a ſpecial manner, inſomuch, that afterwards, one ploughing will go as far towards bringing it into tilth as two before.

The quantity of chalk ſhould be proportioned to the ſtubbornneſs of the ſoil; from fifteen to thirty tumbril-loads on an acre.

The virtues of this manure are not exhauſted under, at leaſt, twenty years; nor are they much perceived till the third year; but for twelve or fourteen years the farmer will have reaſon to thank thoſe who adviſed him to the ſtep of chalking his clay lands: and happy is he who can afford to do it, provided he has a long leaſe; for lands not worth five ſhillings an acre have, by this means been, in a year or two, worth twenty. *Muſeum Ruſticum, vol.* II. *p.* 305.

An old experienced farmer in the hundreds of Eſſex has, in the ſame work, given an excellent account of the benefits reſulting from chalk laid on clay lands, where, he juſtly obſerves, it inſinuates itſelf into the ſmall pores, and, raiſing a fermentation, expoſes the clay more to the operations of the froſts, rain, ſun, and air, by which means its too coherent particles are looſened, and it is reduced to a ſtate of pulverization.

"We all know, adds this intelligent huſbandman, that clay, when reduced, either by fermentation or attrition, into ſmall and minute particles, is an excellent ſoil for affording plenty of nouriſhment to almoſt every kind of vegetable: it is therefore natural to us, when poſſeſſed of a ſtiff clay, to go in ſearch of means for producing theſe deſirable effects.

"Chalk has been long allowed the palm in this reſpect: our anceſtors, the ancient Britons, uſed it with great ſucceſs; and the practice, as warranted by conſtant experience, has been handed down to the preſent age: is it not then a pity but a cuſtom ſo profitable ſhould not be made known to every part of his majeſty's dominions?

"The chalk we uſe in Eſſex is moſtly brought from Kent: it agrees well with our clays, and many fine fortunes have been made in this country by chalking farms: yet what may appear very ſtrange, but is not leſs true, this ſame chalk, when laid on the clayey lands in Kent near the pits, does by no means anſwer the farmer's expectation.

"It has been a common ſaying among farmers, that chalk laſts only for a certain number of years, after which it leaves the land in a worſe ſtate than that in which it found it: but this is probably a miſtake, owing to prejudice, negligence, or ignorance.

"When land has been chalked, under a notion it cannot be hurt by cropping, they generally keep it in almoſt conſtant tillage, and it pays well for the ploughings; but then the ſoil being, by ſuch conſtant working, reduced to a pulverized ſtate, the chalk eſcapes through the now-enlarged pores of the clay, and forms a cruſt under the looſe ſtratum on the ſurface of the hard clay beneath, being waſhed down by the rains.

"The particles of clay being now deprived of their coatings of chalk, adhere one to the other, enlarge their ſurfaces, and become at length a coherent maſs of ſtiff ſoil, like what it was before the land was chalked at all, not worſe in quality, but nearly in the ſame ſtate. Probably the chief reaſon which induces farmers to think the land impoveriſhed by chalk is, becauſe they have, whilſt the manure acted with its full vigour, being for many years uſed to great crops, forgetting, or perhaps never knowing, what crops the land yielded before any chalk was laid on it.

"A great deal of care is requiſite in land after it is freſh chalked: if the large lumps are buried before they are ſtrongly impregnated with the influences of the atmoſphere, they will lie under ground undiſſolved, in a hard maſs, for a great number of years, without benefiting the land in the leaſt. For this reaſon, the farmer muſt not be in a hurry to bury his chalk: in fact, the longer it lies above ground the better, as it will then gradually be reduced into an impalpable powder, which, being mixed and incorporated with the clay, leſſens the coheſion of its parts, enlarges its pores, and diſpoſes it to yield that nouriſhment to vegetables, which, in its natural ſtate, it is too retentive of.

"Clay is, by nature, poſſeſſed of a large ſtock of the food, whatever it be, which plants moſt delight in; but it is a ſtubborn ſoil, and will not, till compelled to it by ſome extraneous cauſe, give forth any of its riches. If it is pulverized by the inſtruments of huſbandry which act by attrition, it becomes a proper bed for the reception of the roots of vegetables; but this pulverization is not to be effected without great expence of time and trouble: and it was the difficulty of this operation that induced our anceſtors to ſearch for ſome eaſier and ſhorter method for reducing the ſolid particles of clay; they effected it by means of fermentation, and this fermentation was raiſed, for the moſt part, by rotten horſe-dung.

"When this manure became ſcarce, and difficult to be procured, it was neceſſary to have recourſe to ſome other remedy to correct ſtiff ſoils. Chalk was found well adapted to the purpoſe: the uſe of it was after many years almoſt univerſally adopted, and experience has now, for many ages, juſtified the practice.

"It has been already obſerved, that chalk improves clay, not by adding to it any vegetative quality, but by mixing intimately with its ſubſtance, and leſſening the coheſion of its parts.

"Let us, by way of illuſtration, ſuppoſe any given quantity of clay mixed and incorporated with a proper proportion of chalk, it will be found that the clay will poſſeſs a degree of lightneſs, which nature has denied it. Let this mixed earth be ſpread on a floor expoſed to the weather in winter time; let it be frequently ſprinkled with water, and be ſtirred about ſeveral times a day for ſome months: on an examination, it will then be found, that the chalk has ſubſided, and the clay become more compact than it was, but not ſo compact as it was before any chalk was mixed with it.

"The ſubſided chalk will form a complete ſtratum under the bed of clay.

"I have been the more particular in this account, becauſe on the principle of ſubſidence I have founded a practice, which I have experienced to be profitable to myſelf, and therefore I think it not totally improper to be recommended to the notice of others.

"I had

" I had heard it long complained of, that the benefit reſulting from chalk ceaſed after a courſe of years. I always thought, and indeed found, that the chalk ſubſided: this made me form an opinion that the chalk, even after it had ſubſided, might, in part at leaſt, be retrieved; for the earth, which had been looſened to a certain depth, was, at the bottom of the looſe mould, a hard compact body, which the chalk could not penetrate: here therefore it muſt, of courſe, reſt in its ſubſidence, forming a thin coat on this hard body.

" About forty years ago I chalked the greater part of my farm in the manner preſcribed by the cuſtom of this country. For about fourteen years I enjoyed very good crops; but at the end of that time they began to fail a little. As neceſſity is the mother of invention, I came to a reſolution of trying an experiment on a field of twenty acres: accordingly, when the time came in which it was to receive a whole year's fallow for a crop of wheat, I cauſed the whole of it, ſoon after harveſt, to be ploughed twice in a place, one plough following another in the ſame furrow.

" By theſe means I turned up an intire new earth, on which I immediately laid in the proportion of about three loads of chalk an acre, ſuffering it to lie rough all the winter.

" In the ſpring I gave it a ſecond ploughing, and beſtowed on it three more ploughings before Chriſtmas, when I again left it rough for the winter.

" I muſt not, however, fail obſerving, that in all the plowings after the firſt, the ſhare went only the ordinary depth.

" In the ſecond ſpring I raiſed as fine a mould as I could, by various operations, and ſowed the field with barley, of which I had, at harveſt, a crop to my entire ſatisfaction: my next crop was wheat, on which I ſprinkled ſome clover-ſeed, which brought the land into the uſual courſe of huſbandry.

" The reaſon why my land begins to fail, in about fourteen years after chalking is, becauſe I allow more ploughings to each crop than any of my neighbours, and theſe frequent ſtirrings cauſe the chalk, as I imagine, to ſubſide ſooner.

" My method anſwered ſo well, that I managed all my chalked land in the ſame manner with good ſucceſs; and had, in conſequence, a ſucceſſion of good crops for ten years more.

" When the ten years were expired, I gave my land another trench-ploughing, which never failing to recover the chalk, I renew it at regular intervals, but lay no freſh chalk on it after the firſt trench-ploughing, being in all the reſt content with what is already in the land.

" This method has ſtood the teſt of many years experience, and I have not the leaſt reaſon to aſcribe it to any thing peculiar in the quality of my ſoil: why, therefore, ſhould it not ſucceed as well with others as it has done with me?

" Let me perſuade ſuch of your readers, as it may any ways ſuit, to make the experiment; it cannot be any great expence, and the reſult may turn out very greatly to their advantage.

" This doctrine of the ſubſidence of chalk is certainly founded on reaſon: the predominant natural ſoil will always precipitate that which is only adventitious, and in ſmaller quantity; for the ſame obſervation holds good when clay is laid on chalk.

" This ſubſidence may alſo be obſerved when clay is laid on ſand, or ſand on clay, as a manure; and might, perhaps, be extended to many other articles, ſo as to be deemed a general principle.

" Few know the benefits reſulting, on ſome occaſions, from deep ploughing: but in this, as well as in every other matter, diſcretion is to be the grand guide; and I would, by all means, adviſe the farmer to examine into the depth of his ſoil, by remarking what is thrown out of his ditches, or by the help of a borer. Let him judge by this, and he cannot well go aſtray.

" I muſt alſo give another caution to my honeſt brethren the farmers, which is, not to be in too great a hurry to crop a field after it has had a trench-ploughing; for the ſoil turned up from any conſiderable depth will be ſomewhat crude in its nature, till it is meliorated by the influences of the ſun and air.

" I have generally found that one whole year's fallow is ſufficient to effect this; but two winters and a ſummer I never knew to fail: it is chiefly froſt which contributes to pulverize the chalk, and ſweeten the ſoil; not but that it receives great benefit from the rain and ſunſhine, and particularly from ſnow, which is ſtrongly impregnated with nitrous particles; all I mean to inſinuate is, that one day's froſt, contributes more to ſweeten a ſtiff, rough, ſoil, than two day's ſunſhine, rain, or ſnow.

" Let me in this place hazard a conjecture, which may, however, prove a fact: the reaſon why froſt ſo much contributes to diſunite the particles of clay may be owing to its ſwelling the clods, and increaſing their ſurface: the cavities occaſioned by this ſwelling are filled with ice: when a thaw comes on, wherever the ice was, is a vacuum, and the particles of which the clay is compoſed, being ſeparated one from the other, crumbles and fall in pieces; when they are in this ſtate, and the land has been chalked, a ſingle ploughing, well-timed, will cover their ſurfaces with the chalk-powder, and prevent them from ſpeedily adhering one to the other.

" Your readers, who have been in countries where there are quarries of ſtone, muſt have obſerved, that, whilſt in the quarry, it works better than after it has been expoſed to the ſun; for it hardens conſiderably after it has been out of the quarry ſome time. It is the ſame with chalk, which is apt to be hardened by lying a ſummer in the ſun: for this reaſon, it is adviſable, that the chalk intended for manure ſhould be dug as ſoon as the winter ſets in, and laid preſently on the land. This method and time of chalking may occaſion ſome increaſe in the expence; but the farmer will be well paid for it in the end, and he will, by this management, ſooner reap the benefit of his labours.

" Let it not be imagined from any thing I have ſaid here, that I truſt ſolely to chalk for bringing me good crops; no, I always beſtow, once in a courſe of three or four years, a reaſonable coat of compoſt dung. I do not lay on the chalk with any intention that it ſhould enrich the clay: my deſire is, that it ſhould bring it to the nature of a loam, as the dung will then take effect, and enſure the farmer a large crop, provided he guards himſelf againſt the depredations of weeds, which are too apt to have their ſeeds mixed with the dung made of long ſtraw, and often grow faſter than the corn, with which the land ſhould be cropped. Dung, when prudently applied, is, like many other things, of great

uſe;

uſe; but it is dangerous in the hands of an ignorant land-holder. The expence of procuring it in quantity will ruin him, and his crops will go near to be choaked by the encroaching weeds." *Muſeum Ruſticum, vol.* III. *page* 198.

"If chalk, ſays Mr. Liſle, be laid on clay, it will in time be loſt, and the ground again return to its clay; and if the clay be laid on chalk, in time the clay will be loſt, and the ground return again to its chalky ſubſtance. Many people think the land, on which the other is laid for a manure, being predominant, converts the manure into its own ſoil; but I conceive, in both caſes, the chalk and clay is filtrated through the land on which it is laid, by time, and, being ſoluble by rains into ſmall corpuſcles, is waſhed through the land on which it is laid; for neither of theſe manures is able to unite, in its fineſt corpuſcles with the corpuſcles of the land on which it is laid, ſo as to form ſo ſtrict an union and texture with it as the land doth with itſelf, and is therefore liable to be borne downwards with rains, till no ſign of it be left.

"It is ſaid to be a common practice with many tenants in Hampſhire, three or four years before they leave their farms, to chalk their meadows; by which means they will for three or four years fling out a great crop of graſs, but that they will be much the worſe for it ever after. This ſeems to carry ſome reaſon with it; for the chalk ſo mellows and opens the pores of the meadow, that it enables the land to exhauſt its ſtrength in all parts: for chalk does not carry ſo much fatneſs as dung does to the land it is laid on; but it diſpoſes the land to bear ſuch crops by its ſweetneſs, and well diſpoſing of, and correcting an ill quality the land had before: but ſtill I do not ſee that this is any objection to the chalking of meadows, provided, whilſt, by virtue of the chalk, they are bearing ſuch burthens, you take care to refreſh them with dung.

"Though chalk laid on meadows enables them to give a great crop for three or four years, and will then impoveriſh them, yet I take it to hold quite contrary in paſture; for the graſs being thereby ſo much ſweetened and increaſed, keeps conſtantly ſo much the more ſtock, by which it is maintained always in the ſame vigour.

"It is probable, that chalk ſpread on ſandy or wood-ſeary ground, laid up for paſture, may waſh and ſink in, and fill up the interſtices, and thereby conſolidate and mend the texture of ſuch ground, and ſweeten it, as it is a great alkali; and though in time moſt of the chalk may be waſhed downwards, ſo that the ground may loſe its virtue, yet I do ſuppoſe the ſtrength of the ground may ſtill continue much better, by reaſon that ſuch manure having made the ſward of the graſs come thicker and ſweeter, the good paſturage on both accounts enlarges the quantity, and betters the quality of the dung the cattle leave on it, which, in return, maintains a better coat and ſurface to the ground: and as chalk fills up the vacuities of ſandy, or wood-ſeary ground, ſo, on the contrary, it inſinuates its particles into obſtinate clayey and ſtrong land, and divides it, by making in a manner, a ſciſſure, thereby hollowing and mellowing it; ſo that the two contrary extremes are cured by chalk.

Chalk laid on hop-clover and rye-graſs is a mighty ſweetener and improver of theſe graſſes, being laid upon it after harveſt, at the beginning of the winter, or whenſoever one can beſt tend it; the benefit will be ſoon conſpicious, eſpecially if the ground be of a ſour clay, and apt to run to coarſe graſs. *Liſle's Huſbandry, vol.* I. *p.* 66.

CHALKEY *Lands*, are thoſe which are impregnated with chalk, and from their white colour, are in ſome counties, called white lands.

The beſt produce of corn in chalky lands, is barley and wheat; oats will do well on them. Their natural produce for weeds is poppies, May-weed, &c. For graſs-ſeed, ſaintfoin, trefoil, and, if rich, clover. The beſt manure for theſe lands is rags, dung, folding of ſheep, &c. Theſe lands, if rain happens to fall on them juſt after ſowing, before the corn gets up, will cauſe the earth to bind ſo hard, that the corn cannot get through it; but may be much helped by a light harrowing.

In Hertfordſhire they manage theſe lands for corn in the ſame manner as they do their clay lands. In Oxfordſhire they commonly manure theſe lands with half rotten dung, which, they ſay, prevents the binding of it, and ſome mix it with ſand, which cauſes it to work ſhort, eſpecially if any thing dry; they commonly ſow them there with wheat, miſlen, and barley; only after wheat they ſow peaſe or vetches: in ſowing of which they are obliged particularly to take care to have fine weather, becauſe of the land's binding; but if they have only two nights dry weather, they will do well enough. *Mortimer's Huſbandry, vol.* I. *pag.* 68.

CHANFRIN, the fore-part of a horſe's head from one hand to the other.

CHANGE *of crops*, a very judicious part of huſbandry, conſiſting in a change of different ſpecies of grain on the ſame ſoil.

Experience ſoon taught men, that even the moſt fruitful ſoil cannot conſtantly yield the ſame grain; and this of courſe laid them under a neceſſity of ſeeking for means to remedy the defect. They found the plough the moſt ready, and perhaps the moſt effectual: and hence all the antient writers ſo highly commend a thorough ploughing. At the ſame time the apparent loſs of the produce of the ground during the year of fallow, put them upon enquiring how this inconvenience might be prevented, conſiſtently with keeping the land in good heart. Repeated obſervations convinced the Romans, the moſt attentive of all nations to every thing relative to huſbandry, that, beſides the alternate reſting of the land, wheat may, as Pliny obſerves, be ſown after lupines, vetches, beans, or any other plant which has the quality of fertilizing and enriching the ſoil. This, ſays Mr. Liſle, deſerves to be well noticed, becauſe our farmers imagine they cannot make their rent, if they pay twelve ſhillings an acre, without ſowing their land every year; nor will they be perſuaded to lay it down to graſs.

The moſt rational change of crops hitherto pointed out by any writer, is the following, planned by Camillo Tarello, and which he preſented to the ſenate of Venice in the year 1566.

"Let the ploughings hitherto given to corn land divided into two portions (each of which being reſted every alternate year, receives four ploughings that year) be transferred to the half of one of thoſe portions, ſo that it be ploughed eight times, including the ſeed ploughing; I mean, that every farm in tillage be divided into four equal parts, and that only one of theſe parts, taking them alternately, be ſowed with corn in any one year, after it has been ploughed eight times. Two

of

of the other parts ſhould be laid down to graſs; and the fourth ſhould be fallowed a year, during which it ſhould receive the above-mentioned number of ploughings.

"He, therefore, who has now, for example, ten acres under corn, ſhould for the future ſow only five, and ſo in proportion for a larger or leſſer extent; and all the manure and labour formerly beſtowed upon his ten acres ſhould be appropriated to the five only; that is, he ſhould plough them eight times, unleſs the ſoil be extremely light.

"The huſbandman ſhould begin to plough in October or November, about ten months before he ſows, or ſooner if he can; but always in dry weather. He ſhould lay on his dung before the laſt ploughing; and ſhould not ſow more than two thirds of the quantity of ſeed hitherto commonly uſed, and that ſeed ſhould be of the growth of the country.

"Whoever follows this method may always depend of reaping the following advantages:

"1. This way of cultivating land leſſens the expence and labour; it being eaſier to plough one acre eight times, than to plough two acres four times each: becauſe, after the third time, an acre and a half, at leaſt, may be ploughed as ſoon as an acre could have been before; and if he begins his work in October or November, while the land is in good condition for ploughing, he may continue it the following year, at ſuch times as he will have little more urgent buſineſs, ſo as to have four ploughings done about the end of May. By this means the four ſummer ploughings will not require ſuch ſtrong ploughs as ſome people now uſe, to the great hurt of their cattle, and fatigue of the ploughman, becauſe the ground will be already well looſened.

"2. Theſe repeated ploughings will deſtroy the ſeeds and roots of weeds, which rob the corn of its food, choak it, and hinder it from growing.

"3. A field reſted, and then prepared in this manner, will yield more than double the produce of two equal ſpaces of land cultivated in the common manner, as I have often experienced. This is more than doubling one's income.

"4. Over and above this great advantage, we likewiſe ſave two thirds of the quantity of ſeed hitherto commonly uſed: for, by ſowing only a quarter inſtead of half of the land in tillage, there is an immediate ſaving of half of the ſeed formerly required; and by ſowing only two thirds of the uſual quantity upon that quarter, we again ſave two twelfths, that is one ſixth of all the former ſeed: now half and one ſixth makes two thirds, to be deducted from the former uſual quantity.

"5. We ſhall have a ſufficiency of ſtraw of every kind for all our uſes, eſpecially for litter and dung, ſo indiſpenſibly uſeful.

"6. We ſhall have hay and fodder enough to keep many cattle; becauſe we may, and ſhould ſow one half of our ground with graſſes, which will thrive extremely well, while the land is thus reſted for two years, in order to be afterwards broken up, ploughed, and ſowed with corn in its turn: for I again adviſe ſowing only a quarter part of the whole farm with corn, and breaking up another quarter immediately after ſeed-time, before winter: and, on the contrary, neither of the other quarters ſhould be ploughed during two years. But as the earth is deſtined continually to yield productions of one kind or another, even while it reſts, we ſhall do well in following the path pointed out by nature, by helping it to produce clover, and other plants fit for fodder, which are of ſingular ſervice to us, not only on account of the hay we reap from them, but alſo becauſe their roots greatly improve the ſoil. In the country about Breſcia, plentiful crops of the fineſt flax are reaped from fields where a quantity of clover has been lately mowed; and lands are let there for a great price, not only becauſe the ſoil is rich, and can be watered, but alſo becauſe it has juſt been under clover. If ſuch value is ſet upon land intended only for flax or millet, how much more would good wheat land juſtly deſerve?

"7. A ſeventh advantage will be, that land reſted regularly for two years (I ſay, with Virgil, that it reſts when it is not ploughed) being well conditioned, afterwards well prepared, ploughed, enriched by the roots of the graſſes, and kept clear of weeds, will yield crops more than twice as great as any we now reap; a truth which I have practically experienced, which the moſt ſenſible and moſt judicious huſbandmen that ever lived have long told us, and of which a trial will ſoon convince the moſt incredulous.

"8. One of the moſt conſiderable advantages attending this method, is the eaſe with which a great number of cattle may be reared, by means of the increaſed quantity of hay and green fodder. We ſhall conſequently have more horſes, more oxen, more cows, more ſheep, and more poultry. Every one knows of what infinite ſervice all theſe are, to feed us, to cloath us, and to help us in our work. He, therefore, who has hitherto been obliged to have two yoke of oxen will, in this method, want only one, and may, inſtead of the other, feed two or three cows: for as the labour is hereby leſſened, and the quantity of good fodder increaſed, two oxen will be ſufficient to plough the land, eſpecially as the ſoil will, by theſe means, be brought daily into better and better tilth.

"9. From hence naturally ariſes a ninth advantage, which is, the quantity of manure produced by the increaſe of cattle and of fodder; an advantage which no good huſbandman will neglect to purchaſe, if the means of doing it are but pointed out to him.

"The tenth and laſt of the advantages which I ſhall here enumerate, as reſulting from this new method of culture, is, that poor and barren lands are hereby rendered, by degrees, good and fertile: for ſuch is the conſtitution of the earth, that ploughing and manuring alter its very nature, and improve it more and more, as experience repeatedly demonſtrates. Valerius Maximus inſtances the ſtriking example of Maſiniſſa, king of Numidia, who made agriculture flouriſh ſo much, that he left his country, which he found barren and deſolate, ſtored with riches and every good thing. It is in our power to do the ſame. On the contrary, it is not leſs true, that even though the earth be rich and good, it will yield but little fruit, if it be not well cultivated; reſembling therein the capacity of the human mind, which according to Cicero's fine compariſon, is enlarged only by ſtudy and exerciſe. Induſtrious labour will not only procure us the neceſſaries, nay, the ſuperfluities of life, but will even change a barren country into a kind of garden. *Ricordo d'Agricultura di Tarello.*

M. Duhamel, after obſerving that the French farmers, in general, change their crops, not on any principle dictated by reaſon, but merely becauſe it was the cuſtom

of their forefathers, or they themſelves perhaps have occaſion for ſome particular growth, draws a pararellel between the practice of dividing arable land into three parts, or into two, in order to their being alternately ſown, and reſted. "I have, ſays he, ſome acquaintance with the methods of practice in Guienne, and in part of Normandy; and am obliged to M. le Baron de Sournia, governor of Querebus, for enabling me to give an account of the methods uſed in the neighbourhood of Perpignan, where his eſtate lies.

"In this hot climate they ſow their lands in September, and begin to cut wheat about the twelfth of June; ſo that their harveſt is generally finiſhed by Midſummer.

"They divide their lands into two portions only; ſo that in one year they ſow wheat, and the other the land ſhould be ſuffered to reſt. But, on ſuch part of their lands as are moſt valued, they have ſeveral crops during the year of reſt: this impoveriſhes their lands, and they are obliged to ſow their wheat too late, which leſſens the crop. We ſhall mention an inſtance given by M. Sournia.

"In land they can water, they ſow clover immediately after wheat-harveſt, ſcattering the clover-ſeed among the ſtubble. The land is then immediately watered, and is afterwards ſeveral times repeated during the ſummer: in the winter they feed it with ſheep and lambs. Such as have no flocks ſell their paſture to the upland farmers, who have flocks, but no winter fodder, their land being covered with ſnow: this paſture therefore fetches a very high price.

"In ſpring, when the green fodder has been eaten down by cattle, they water the land, and by that means the clover ſprouts apace; when it is in bloſſom they mow it, make it into hay, and lay it up with the reſt.

"Immediately after this crop, they dung the land; and ſuch as are not afraid of exhauſting it, plough it, and ſow either kidney-beans, or ſmall millet: but as they cannot plough for wheat till theſe crops are off the ground, there is not time ſufficient for giving the land proper tillage; the ſowing is retarded, and the rich particles of the dung are partly conſumed by theſe crops, while the manure might be more uſefully employed on lands they cannot water. M. de Scurnia is, by repeated experience, convinced, that, to have good crops of wheat, they muſt be contented with the crop of clover, and only ſow kidney-beans, millet, &c. in ſmall quantities for the uſe of the family.

"In Guienne, as well as in Anjoumois, they raiſe a crop of maize, which is a great impoveriſher of the ground, during the year of fallow.

"The good huſbandmen alſo think, that in the rich lands, which they cannot water, it is the beſt, in a farm of three hundred and fifty acres of wheat, to be careful to give proper tillage to the one hundred and fifty acres that ſhould be in fallow, to make them proper for the reception of wheat. This is alſo the practice of ſome diſtricts of Normandy, where the climate being colder, and the ſoil more backward, they have ſcarcely an opportunity of having any crop but wheat. However, when the land has been well dunged and tilled for maize, as they beſtow three ploughings on that plant, there is commonly the next year a very good crop of wheat.

"It is evident, that by dividing a farm, that has three hundred acres in tillage, into two equal portions, which are ſown alternately every other year, the tenant, during a nine years leaſe, will reap one thouſand three hundred and fifty acres of wheat: whereas, if the land be divided into three portions, it will amount to nine hundred acres only. But, in the latter caſe, the former has nine hundred acres of ſpring corn, which being eſtimated at half the value of the wheat, make it juſt equal to one thouſand three hundred and fifty acres of wheat. It follows therefore, that in grazing countries, where they plough with oxen, and uſe but few oats, it is moſt advantageous to divide the land into two portions; but that this is not to be done in farms that are tilled with horſes, becauſe the neceſſary purchaſe of oats would amount to the value of the four hundred and fifty acres of wheat extraordinary.

"The farmers about Bayeux, in Lower Normandy, have two methods of changing their crops.

"According to one of thoſe methods, 1. They ſow buck-wheat towards the end of June; 2. When the roots and ſtems of this plant are dead and withered, which is about All-ſaints day, they plough, and immediately ſow wheat: the wheat is therefore ſown on one ſingle furrow. Theſe lands have indeed been ploughed for buck-wheat, and even thoroughly dunged; and plenty of manure can ſupply the place of good tillage, and the latter can ſupply the place of the former. 3. After reaping the wheat, they plough in the ſtubble as ſoon as poſſible; and, after giving the land a ſecond ploughing in February or March, they ſow it with oats; or a third ploughing is beſtowed upon it, in order to crop it with barley: 4. They plough in the barley ſtubble in winter, and after giving the land one ſpring ploughing, ſow either peas or tares: 5. Immediately after this crop is off, they turn down the land, that it may receive two ploughings before October, when it is ſowed with wheat. 6. The following year they ſow oats mixed with a little clover-ſeed; after which it is laid down in paſture for three or four years. It would be needleſs to mention that the farmer varies the order of his ſucceſſive crops, according to the nature of the ſoils, and his own occaſions; but by this method, ſix crops are reaped in ſix years; two of wheat, two of oats, one of buck-wheat, and one of peas or turnips; and the field is then left in clover to be fed for four years.

"According to the other method, they ſow no buck-wheat on the land they break up; it is left in fallow from February or March, when it is turned up, till October; and during this interval they manure it, and give it ſeveral ploughings to prepare it for wheat. In this caſe the crop is generally more plentiful, than when buck-wheat has been ſown. In other reſpects, the change of crops is the ſame as was mentioned before." *Culture des Terres, tom.* VI. *p.* 34.

The changing of crops, upon rational principles, though of infinite conſequence in agriculture, ſeems to have been neglected, and even forgotten, after the time of the ancient Romans, till Camillo Tarello pointed out its great importance, as we have already obſerved in this article: nor do we, ſince him, find much attention paid to this eſſential part of huſbandry, till very lately, when the culture of turnips probably gave the

the uſeful hint; the farmer obſerving, that his land, inſtead of being impoveriſhed by that root, was enriched, and prepared to yield a better crop of barley in the ſpring. This might naturally ſuggeſt to him, that other ſucculent plants, which cover the earth with their leaves, might have the ſame effect. The ſucceſs has anſwered his utmoſt expectation: for it is now found that a fallow does not become neceſſary in ſeveral years; the ground being kept in heart by a variety of crops when rightly timed, and properly managed. The Society for the Improvement of Agriculture in Scotland, from whom we ſhall borrow the following judicious inſtructions, have the honour of ſetting this diſcovery in its proper light.

They obſerve, "That ſome crops, as peas, beans, clover, and all plants of the pulſe kind, are enrichers and cleaners of the earth; while wheat, oats, barley, and the whole tribe of vegetables, whoſe roots are fibrous, and ſpread far, impoveriſh and rob the ground. The latter are alſo foulers of it, by giving way to weeds and graſs, which, being the natural product of every ſoil, are more readily nouriſhed by it, than any plant which it does not ſpontaneouſly produce; and if the earth be fed with any ſort of manure, it will, while the weeds and graſs remain undeſtroyed, like a tender mother, cheriſh and nouriſh them in proportion to the food ſhe receives.

"Wheat and oats are great robbers of ſoils. Wheat remains a long time in the ground, during which the land untils itſelf, coaleſces, and becomes of the nature of uncultivated earth; while the weeds, meeting with no oppoſition, ripen, and ſhed their ſeeds. Oats do not continue ſo long: but they bind the ſoil by their ſtrong roots, and give many weeds time to ripen. Barley, as it ſtands only a few months, and ſeveral ploughings are given for it, binds the earth leſs than either wheat or oats. Peas, beans, tares, &c. are ſuppoſed to draw much of their nouriſhment from the atmoſphere, and that in proportion to the ſucculency of their ſtems and leaves, whereby it is probable their roots diſcharge a moiſture under ground; and their leaves, covering the ſurface of the earth, return the moiſture and dews deſcending through them, which mellow and rot them into a kind of manure." *Maxwell's Collection*, *p.* 219.

From the above obſervations, the farmer will be able to vary his crops in ſuch a manner as always to keep his ground in heart, and free from weeds; particulars which cannot fail of producing very great advantages.

CHANNEL, of a horſe, is the hollow between the two bars of the under jaw bone, in which the tongue is lodged.

CHARCOAL, a ſort of fuel, conſiſting of wood charred, or half burnt.

The duſt of charcoal has been found, by repeated experience, to be of great benefit to land, eſpecially to ſuch as is ſtiff and ſour. It is to be uſed in the ſame manner as ſoot and wood-aſhes. *See the articles* ASHES *and* SOOT.

CHARLOCK, called alſo *Chadlock*, *Catlock*, *Carlock*, and *White-Rape*, is a weed too generally known to need a particular deſcription, the figure we have given of it on Plate V. Fig. 32. will be abundantly ſufficient. Almoſt the whole plant is covered with bent pellucid hairs.

There are two ſorts of charlock, one bearing white, and the other yellow flowers, but they ſeem to be only varieties of the ſame plant. The young plants of charlock ſo nearly reſemble thoſe of turnips, that they are not eaſily diſtinguiſhed but by the taſte; the charlock being hot and bitter, and the turnip mild. Farmers ſhould therefore be very careful in weeding their turnips, leſt they miſtake them for charlock.

Mr. Liſle obſerves, that cold wet lands are always more ſubject to charlock than white or chalky lands: becauſe the charlock-ſeed being very oily, reſiſts putrefaction, and is not eaſily opened or penetrated by moiſture, whereas white and light earth is ſoon dry after rain, and the water does not continue long enough on it to make ſuch ſeed germinate ſo effectually as in the other. By an experiment which he made in ſowing charlock-ſeed and turnip-ſeed at the ſame time, he found that the turnips will appear in three days, but the charlock in not leſs than ten. A hint that may prove very uſeful to the huſbandman. *Liſle's Huſbandry*, *vol.* II. *pag.* 297.

Mr. Mortimer, after remarking that both the white and yellow charlock are very prejudicial to corn, and that ſome lands are very ſubject to it, eſpecially if manured with cow-dung alone, which he thinks increaſes it more than any other manure, unleſs it be mixed with horſe-dung, or ſome other hot manure, mentions his being told that a perſon who had vaſt quanties of this weed in a field of barley, mowed the whole when the charlock was in flower, and ready to ſeed, which is commonly about the middle of May, as low as he could, without taking off more than juſt the tops of the blades of the barley; and that this gave the corn an opportunity to get above it, in ſuch a manner, that he had four quarters of barley on an acre. He adds, that where a fallow is full of charlock, it will be right to turn in ſheep, which will eat it very readily. *Mortimer's Huſbandry*, *vol.* I. *p.* 311.

CHASE, a word uſed in ſome counties to ſignify a row or rank. Thus in the planting of quickſets, a ſingle chaſe implies a ſingle row; a double chaſe, means another row planted below the firſt, not immediately underneath the upper plants, but under the middle of the intermediate ſpaces. *Liſle's Huſbandry*, *vol.* II. *pag.* 405.

CHATS, the keys of trees, ſuch as the aſh, ſycomore, &c.

CHEDDER-CHEESE, a name given to a very large kind of cheeſe made at Chedder, a village near Mendip-hills in Somerſetſhire, famous for its paſtures. It is common in this place for three or four dairies to join their milk, to make one great cheeſe, which generally weighs from one hundred and fifty to two hundred weight; and which they often ſell at ſix-pence per pound on the ſpot.

CHEESE, a well-known ſpecies of food, prepared from curdled milk, preſſed from the whey, and afterwards dried for uſe. *See the article* DAIRY.

CHEESE-LIP, a bag in which the dairy-women prepare and keep their runnet for making cheeſe. *See* RUNNET.

CHEESE-PRESS, a preſs uſed in dairies for ſqueezing the whey out of the cheeſe. We have given a drawing of the common cheeſe-preſs, on Plate VI. Fig. 1. where AB is the preſs, CE, and FG, are levers moveable

moveable about the points D, E, F, G, by applying the hand at C; S is the ſtone or weight; and H the cheeſe to be preſſed.

CHEESE-RENNET. *See* YELLOW LADIES BEDSTAW.

CHERRY-WINE, a very cooling and pleaſant drink, made from the juice of cherries, properly fermented. The chief care neceſſary in making it, is to let the cherries hang upon the trees till they are thoroughly ripe, by which means their juice, which they yield in great abundance, will be the better perfected and enriched by the ſun; to gather them in dry weather; preſs out their juice, and add a quantity of ſugar proportioned to the ſtrength you deſire in the wine; for the more ſugar there is added to the natural juice of the cherries, the ſtronger and richer the wine will prove, when of a proper age. When this is done the whole muſt be regularly fermented, according to the method laid down under the article fermentation. *See* FERMENTATION.

CHEST, the breaſt, or that part of an animal's body which contains the heart, lungs, &c.

CHEST-FOUNDER, a diſtemper incident to horſes, and occaſioned by an improper treatment of an inflammation between the ribs. For if the inflammation be not diſperſed in time, and the viſcid blood and juices ſo attenuated by internal medicines, that a free circulation is obtained, ſuch a ſtiffneſs and inactivity will remain on thoſe parts as will not eaſily be removed; and this ſtiffneſs is generally called cheſt-founder.

The ſigns of this inflammation, are a ſtiffneſs of the body, ſhoulders, and fore-legs; attended ſometimes with a ſhort dry cough, &c. a ſhrinking when handled in thoſe parts.

Bleeding, ſoft pectorals, attenuants, and gentle purges, are the internal remedies; and externally the parts affected may be bathed with equal parts of ſpirit of ſal ammoniac, and ointment of marſhmallows, or oil of chamomile.

Theſe outward inflammations frequently fall into the inſide of the fore-leg, and ſometimes near the ſhoulder; forming abſceſſes there, which terminate the diſorder. *Bartlet's Farriery, pag.* 57.

CHESNUT-TREE, the name of a tree, which well deſerves the planter's care, affording excellent timber, and a very agreeable ſhade. It will grow to a very great ſize, and ſpread its branches finely on every ſide where it has room.

The leaves are large, and of a lucid green, and continue late in the autumn; nor are they ſo liable to be eaten by inſects, as thoſe of the oak; nor is there any better food for deer, and many other animals, than the fruit of this tree.

Cheſnut-trees are propagated by planting the nuts in February, in beds of freſh undunged earth. The beſt nuts for ſowing, are ſuch as are brought from Portugal and Spain, provided they are not kiln dried, which is generally the caſe of thoſe brought from abroad, to prevent their ſprouting during their paſſage; if they cannot, therefore, be procured freſh from the tree, it will be much better to uſe thoſe of the growth of England, which are full as good to ſow for timber or beauty, as any of the foreign nuts, though their fruit is much ſmaller. The nuts ſhould be preſerved in ſand, until the ſeaſon for ſowing, otherwiſe the mice and other vermin will ſoon deſtroy them. Before you ſet the nuts it will be proper to put them into water, to try their goodneſs, which is known by their weight; ſuch of them as ſwim upon the ſurface of the water ſhould be rejected as good for nothing; but ſuch as ſink to the bottom, you may be ſure are good.

In ſetting theſe nuts, the beſt way is to make a drill with a hoe, about four inches deep, in which you ſhould place the nuts at about four inches diſtance, with their eye uppermoſt; then draw the earth over them with a rake, and make a ſecond drill at about a foot diſtance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, in order to clear the beds, &c. When you have finiſhed your plantation, you muſt be careful that it is not deſtroyed by mice, or other vermin: which is very often the caſe, if they are not prevented by traps, or other means.

In April theſe nuts will appear above ground; you muſt, therefore, obſerve to keep them clear from weeds, eſpecially while young: in theſe beds they may remain for two years, when you ſhould remove them into a nurſery at a wider diſtance. The beſt ſeaſon for tranſplanting theſe trees, is either in October, or the latter end of February; but October ſhould be preferred. The diſtance theſe trees ſhould have in the nurſery, is three feet row from row, and one foot in the rows. If theſe trees have a downright tap-root, it ſhould be cut off, eſpecially if they are intended to be removed again; this will occaſion their putting out lateral roots, and render them leſs ſubject to miſcarry when they are removed for good.

The time generally allowed them in the nurſery is three or four years, according to their growth; but the younger they are tranſplanted, the better they will ſucceed. Young trees of this ſort are very apt to have crooked ſtems; but when they are tranſplanted out, and have room to grow, they will, as they increaſe in bulk, grow more upright, and their ſtems will become ſtrait.

After they have remained three or four years in the nurſery, they will be fit for tranſplanting where they are to remain; for the younger they are planted out the better they will ſucceed. But if they are propagated for timber, it is by much the better method to ſow them in furrows, and let them remain unmoved; for theſe trees are apt to have a downright tap-root, which, being hurt by tranſplanting, often checks their upright growth, and cauſes them to ſhoot out into lateral branches.

If you deſign a large plantation of theſe trees for timber, after having two or three times ploughed the ground, the better to deſtroy the roots of weeds, you ſhould make your furrows about ſix feet diſtance from one another; in which you ſhould lay the nuts about ten inches apart, covering them with earth about two inches deep; and when they come up, you muſt carefully clear them from weeds. The diſtance allowed between each row is for the uſe of the horſe-hoeing plough, which will diſpatch a great deal of this work in a ſhort time; but it ſhould be performed with great care, ſo as not to injure the young plants; therefore the middle of the ſpaces only ſhould be cleaned with this inſtrument, and a hand-hoe uſed to clean between the plants

in

in the rows, and alſo on each ſide, where it will be unſafe for the plough to be drawn; and in hand-hoeing great care muſt be taken not to cut the tender rind of the plant. But for the two firſt years after ſowing, it will be adviſable to dig the ground each winter; becauſe the plants will be too ſmall to admit the hoeing plough, and in ſummer to hand-hoe the ground.

When theſe have remained three or four years, you will, if the nuts have ſucceeded well, have many of theſe trees to remove; which ſhould be done at the ſeaſons before directed, leaving the trees at about three feet diſtance in the rows; at which diſtance they may remain for three or four years more, when you ſhould remove every other tree, to make room for the remaining, which will reduce the whole plantation to ſix feet ſquare; which will be ſufficient for them, till they are large enough for poles, when you may fell every other tree, within a foot of the ground, in order to make ſtools for poles, which, in eight or ten year's time, will be ſtrong enough for making hoops, hop-poles, &c. for which purpoſes they are preferable to moſt other trees; ſo that every tenth year here will be a freſh crop, which will pay the rent of the land, and all other incidental charges, and, at the ſame time, a full crop of growing timber left upon the ground.

Cheſnut-trees were formerly much cultivated in England, and doubtleſs produced good profit to the owners; for the wood of this tree is equal in value to the beſt oak, and, for many purpoſes, far better; particularly for making veſſels to hold all kinds of liquor, it having the property, when once thoroughly ſeaſoned, of maintaining its bulk conſtantly; and is not, like other timber, apt to ſhrink or ſwell; and hence all the large caſks, tuns, &c. for wines in Italy, are made of this timber, as being preferred by the inhabitants to any other timber whatſoever. It is alſo very valuable for pipes to convey water under ground, as enduring longer than the elm, or any other wood. In Italy it is planted for coppice wood, and is much cultivated in ſtools, to make ſtakes for ſupporting their vines, as it will endure ſeven years, which is near double the time any other ſtakes will do. *Millar's Gard. Dict.*

CHEWING-BALLS, the name of a medicine adapted to reſtore a loſt appetite, an infirmity which horſes are often ſubject to, proceeding from a ſalt humour, and a bitter phlegm, which obſtructs the paſſage of the throat, and makes them loath their food.

Theſe balls are made in the following manner: Take a pound of aſſa fœtida, as much liver of antimony; half a pound of the wood of bay-tree; an equal quantity of juniper-wood; and two ounces of pellitory of Spain: pound all theſe ingredients apart into a groſs powder, in order to which the woods muſt be previouſly well dried. Then put them all together into a mortar, and incorporate them with a ſufficient quantity of good verjuice, well clarified, pouring it in by degrees, till the whole is reduced to an uniform maſs. Make the whole into balls of an ounce and a half each, and dry them in the ſun. Wrap one of theſe balls in a linen cloth, and faſtening a thread thereto, make the horſe chew it for two hours in the morning, and he will eat as ſoon as you take off the bridle; do the ſame at night, and continue this method till the horſe recovers his appetite. When one ball is conſumed, put in another.

Theſe balls may be uſed on the road, as you travel, being faſtened to the bit of the bridle.

CHICKLING-*vetch*, called by gardeners, the common everlaſting pea, and by C. Bauhine, *lathyrus latifoliis*, a perennial plant, growing naturally in many parts of England.

A correſpondent of the editors of the Muſeum Ruſticum recommends this plant as well deſerving cultivation for the food of cattle, as the root, which will grow in almoſt every ſoil, yields every year a great burden of excellent provender.

"I ſowed, ſays this gentleman, three years ago, a rood of land, light, and but poor in quality, with this ſeed: the work was done early in the ſpring, the land being prepared as for barley.

"I ſowed it not in the broad-caſt way, as I ſhould have found it much more difficult to keep down the weeds; but I cauſed a ſlight furrow to be drawn the length of the land, with a light plough; and when the ſeed was thinly ſprained, or rather dropped into this, another was drawn at a foot diſtance, in which the ſeed was dropped in the ſame manner.

"An interval, or fallow ſpace, was then left at leaſt two feet wide; and then two more rows of the vetches, till the whole land was ſown. I muſt obſerve, that I covered the ſeed by means of a light harrow with wooden tines, drawn backward and forward acroſs the land.

"When the plants came up, I had them well hoed to clear the ground of weeds; and when they grew a little ſtrong, they were ſet out with the hoe to about a foot diſtance in the rows, that they might have room to ſpread and branch.

"The firſt year they yielded no great quantity of fodder, but they have ſince made me ample amends.

"The ſecond ſpring they came up very ſtrong and vigorous, branching out much; and when I turned a couple of horſes in to feed, they were very fond of it, eating it very greedily, though they were taken out of a good natural upland-paſture.

"The laſt ſummer the land was almoſt entirely covered, and it yielded a great deal of ſeed indeed; for experiment ſake, I cauſed a few roods to be mowed juſt before it flowered, and it made good hay, ſweet, and without being ſticky.

"I therefore think, from my little experience in the matter, I have ſome foundation for recommending this plant to the notice of the public. I could wiſh, indeed, I had been more accurate in my experiment; but what is paſt cannot be recalled: and ſome other perſon may, perhaps, hereafter, give the public more uſeful information on this head."

CHICKWEED, called by botaniſts *cucubalus*, flowers early in the ſpring, and, if it be ſuffered to grow, ſeveral times in the courſe of the year. The way to deſtroy it is therefore to pluck it up from time to time, before it can ſhed its ſeed.

The berry-bearing ſort, which grows with ſmooth, erect ſtalks, globular empalements, and ſtamina longer than the petals, is the wild lychnis, or white behen of the ſhops. This is a very rambling weed, natural to moſt parts of England, and is frequently called ſpatling poppy. Its roots are perennial, and ſtrike ſo deep into the earth, that they are not eaſily deſtroyed by the plough; for which reaſon, bunches of this plant are too common among corn, in land which has not been perfectly well tilled.

tilled. Summer fallows, and carefully harrowing out every part of the roots, which ſhould then be burnt, will here prove the beſt and moſt effectual remedy.

CHICKWEED is alſo the name of an annual weed, called by botaniſts *alſine*. This weed, though it periſhes every year, will ſoon become very troubleſome, if ſuffered to ſtand till it ſheds its ſeeds, which Mr. Liſle thinks it will do ſeveral times in the year; for he obſerved on the 23d of October, a great deal of this weed, the branches of which carried many buds of bloſſoms, many flowers full blown, and many pods with white ſeeds almoſt ripe; ſo that its increaſe may be the leſs guarded againſt by any ſort of huſbandry in the common way. The repeated horſe-hoeings in the new huſbandry muſt here be of ſingular advantage; and, at all events, particular care ſhould be taken, to prevent the ſeeding of this plant upon dung-hills, where it is too often ſuffered to grow unnoticed and undiſturbed: for its ſeeds ſcattered there, and intermixed with the dung, will ſoon give birth to a multitude of weeds in the land upon which it is ſpread; unleſs it be kept, as indeed all dung uſed for manure ought to be, till it is thoroughly rotted, and the ſeeds have loſt their vegetative power.

To CHISSUM, to put forth roots, to grow.

To CHITT, to ſprout out, to grow.

CHITTED, ſprouted, ſhot out, grown.

CHIZZLE, bran, the huſky parts of ground wheat.

CHOCKY, the ſame with chalky, reſembling chalk, mixed with chalk, or of the nature of chalk.

CHOLIC. *See* GRIPES.

CHURN, the name of the veſſel in which the cream is coagulated by agitation

There are two ſorts of churns, one called the common, or Dutch churn, and the other the barrel churn.

The common churn is repreſented on Plate VI. Fig. 2, 3. where Fig. 2. is the arbor or ſtaff; and Fig. 3. the body of the churn. The lower end of the ſtaff is placed in the body of the churn, and being raiſed with a pretty quick motion by the hand on the upper part of the ſtaff, the cream in the body is agitated, and by that means coagulated into butter.

Fig. 4, 5, 6, 7. repreſents the ſeveral parts of the barrel-churn.

Fig. 4. is the arbor of the barrel-churn. Fig. 5. its bung, or cover. Fig. 6. the body of the churn. And Fig. 7. the ſtand on which it is placed. The arbor cannot be taken out of the body of the barrel-churn, without the help of the cooper; but is here repreſented by itſelf, to ſhew the manner in which it is made. In Fig. 6. the churn is repreſented with the arbor on it, but not placed on its ſtand, in order to ſhew the latter. When the utenſil is to be uſed, the churn is placed upon its ſtand; the cream poured into it through the bung-hole, and the hole cloſed with its bung. The arbor is then turned round pretty faſt, by which the four leaves of the arbor agitate the cream, and coagulate it into butter. *See the article* DAIRY.

CIBOULES, a ſort of ſmall onions propagated only by ſeeds, which, if ſown in March, will be ripe in Auguſt; and theſe are reckoned the beſt for keeping; but they may be ſown in almoſt every ſeaſon. They differ from the onions, of which they are probably a degeneracy, in that they do not form bulbs at their roots, but ſhoot out ſeveral upright blades, and thoſe which produce the greateſt number of theſe, are reckoned the beſt. Their culture is the ſame with that of onions, like which they muſt be thinned, and well weeded. They will increaſe greatly, even in very dry ſummers, if they have been tranſplanted into beds of good earth, and thoſe beds are kept well watered. The reddeſt, hardeſt, and mildeſt are the moſt eſteemed.

CIDER, *or* CYDER. *See the article* CYDER.

CLASPERS, the threads or tendrils of creeping plants.

CLAVER, a word uſed in ſome counties of England for clover. *See* CLOVER.

CLAW, the foot of a beaſt or bird, armed with ſharp nails.

CLAY, and unctuous and tenacious earth, juſtly accounted the ſtiffeſt of all ſoils.

Clays are of different ſorts, and of as different colours. One kind of them is ſo obſtinate, that ſcarce any thing will ſubdue it; and another ſo hungry, as not to be ſatiated without uncommon pains, becauſe it abſorbs whatever is applied, and turns it to as bad a clay as itſelf. Some clays are fatter than others, ſome more ſlippery; all of them tenacious of water on the ſurface, where it ſtagnates, and chills the plants, without penetrating the ſoil; and in dry ſeaſons they harden with the ſun and wind, are very barren, and extremely untractable. The cloſeneſs of clay hinders plants from extending their roots to ſearch for their neceſſary food, and prevents the entrance of water, which would help to convey it to them.

The more unctuous and fat clay frequently lies upon the other, and has often a bed of chalk beneath it: but neither is this worth any thing till looſened, and fitted to admit the influence of the ſun, air, froſt, &c. The blue, white, and red clay, if ſtrong, are all unkind: the ſtony and looſer ſort is ſometimes tolerable; and the light brick-earth does very well with moſt fruit-trees.

Clay, in general, of whatever kind it be, is, of all earths, the very worſt for vegetation: yet even this, as well as any other untoward ſoil, may, with induſtry, and proper correctives, be made to produce roots and plants which require the lighteſt and holloweſt mould.

Among all the manures for clay, ſea-ſand claims the preference, founded upon experience, as beſt ſuited to break its too great cohefion. Dr. Cox has given us a very accurate account of the ſea-ſand uſed by the farmers of Cornwall, by which the lands are greatly benefited, and their crops largely increaſed. Doubtleſs the huſbandmen of other parts of the kingdom, whoſe lands lie within a moderate diſtance of the ſea, might find the ſame advantage from uſing the ſame manure, which many of them are too apt to overlook.

"The ſea-ſand made uſe of in the agriculture of Cornwall, ſays that ingenious gentleman, lies commonly at or near the ſhore. To diſtinguiſh it from what is uſeleſs, it is proper to obſerve, that this ſand is formed by the grating of ſtones, ſhells, &c. rolled, and tumbled over by the waſh of the ſea. If the matter be ſhelfy, as it is called, that is, the particles formed by the rubbing of ſtones only, it is of ſmall value: but if it be notably ſhelly, it is the thing deſired. Of this ſhelfy ſand there are three colours. About Plymouth, and the ſouthern coaſt, it is bluiſh, or grey, like aſhes; which I conceive to be from the breaking of muſcles chiefly, and oiſter-ſhells mixed with it. Weſtward, near the land's-end, the ſand is very white; and in Scilly,

glittering

glittering. This I think comes from the mouldering of moor-ſtones, or a kind of free-ſtone, mingled with the white ſhells of the ſcallop-fiſh, On the north-ſea about Padſtow, and eaſtward of Lundy, the ſand is rich, of a reddiſh-brown colour tinged with yellow, and conſiſts chiefly of the broken ſhells of cockles; which I gueſs to be of that colour there, from the waſh of the Severn, which falls very dirty into the Severn-ſea.

"Beſides theſe differences in the colour of the ſand, there is alſo another in the bigneſs of the grain. The ſmall is reckoned beſt for the tenant, who takes to tillage only for four years; becauſe it works ſooneſt, and yields the moſt ſpeedy return. The larger grain is thought to be more profitable for the landlord, becauſe it abides longer in the ground, and make the paſture afterwards the richer.

"In Falmouth-haven, near St. Mawe's Caſtle, there is a ſort of ſand, or rather coralline, that lies about a foot under the ooze; which ooze being removed, and the bed opened, this ſand is taken up by a dredge, and is uſed about Truroe, Probus, &c.

"Weſt of the mount, in Portcuthnoe-cove, is a large ſhelly ſand. In White-ſand-bay, and about St. Ives, it is very white and ſmall.

"About Minver, Perinſand, and Lelant, the ſands are frequently blown up by the wind, and cover abundance of good land. Some houſes and even churches have been buried in it; nor has any method hitherto diſcovered been able to prevent its devaſtation.

"Of all theſe ſands, the beſt are accounted, as to colour, firſt the reddiſh, next the blue, then the white. As to kinds, the moſt ſhelly, and the coralline are the beſt, eſpecially if it be taken up from under the ſalt-water, either by dredges, or being left almoſt dry by the ebbing of the tide. The blown ſand is accounted of no uſe: and, in general, if ſand be only well drained of ſalt water, ſo that it can be conveniently carried, it is better than that which has lain long drying in the ſun and wind, which takes off much of its virtue.

"Theſe uſeful ſands are carried by lighters as far up into the country as the tides will ſerve for that purpoſe, and there they are caſt on ſhore. From thence they are fetched, in ſome places, by wheel-carriages; but in moſt, by reaſon of the hilline's, narrowneſs, and badneſs of the ways, on horſeback; one horſe carrying about thirteen or fourteen gallons. One man drives ſeven or eight of theſe horſes, tailed together, to the diſtance of nine or ten miles from the ſand-place; and each horſe-load comes to about eight-pence or nine-pence, in ſome places; though not ſo much in others: for where it is dredged out of the ſea, it coſts but twelve or thirteen ſhillings the lighter, containing ſixſcore horſe-loads, at the landing-quay, or ſand place; and where it is loaded from the dry-beach, after the ebb, it is not above four ſhillings the lighter, excluſive of the land-carriage, which is computed at about thirty-two thouſand pounds a year, in the whole of that country.

"When this ſand is brought home, it is ſpread on the ground intended for wheat; or uſually in the firſt crop of four, whatever be the grain. For after four crops, the Corniſh farmers generally leave their land to paſture for ſix or ſeven years, before they till it again: and indeed the graſs is ſo good, immediately after tillage, that they commonly mow it the firſt year, and which they call mowing of gratten.

"The Corniſh acre contains eight-ſcore yards, of eighteen feet to the yard. On one of theſe acres, if near the ſand-place, good huſbandmen beſtow three hundred ſacks, or horſe-loads: if within the reach of three turns a day, two hundred; if within two turns, one hundred and fifty; where only one turn can be made, eighty or an hundred; and ſo in proportion at greater diſtances, even to twenty or thirty ſacks on an acre rather than none.

"The effect generally is, that where much ſand is uſed, the ſeed is as much as the ſtraw little. Land thus manured has produced barley, of which the ear has been as long as the ſtalk it grew on. But where leſs ſand is uſed, there is but little, and that little hungry grain." *Philoſoph. Tranſact. Numb.* 113.

Where this excellent manure is found, it is taken up by a large bag of the ſtrongeſt canvas, to the mouth of which is fixed an iron hoop, or frame, to keep it open, and ſink it to the bottom of the ſea, that it may take up the ſand and coral, as it is dragged along by the bargemen. The Rev. Mr. Borlace ſays, that a barge-load, which is uſualy delivered for ten ſhillings, or leſs, if near the place of dredging, will dreſs an acre, provided the land be tolerably good.

Large quantities of this ſhelly ſand lie neglected on moſt of the coaſts of England. The benefits ariſing from it, particularly when laid on clayey grounds, are indeed ſomewhat ſlow, but they are very laſting. The improvement is not the firſt or ſecond year; becauſe this manure conſiſts of hard bodies, ſuch as the ſand itſelf, ſhells, fragments of coral, and other calcarious ſubſtances, which require time to diſolve them, and which afterwards enrich the land for many years. The beſt is that which is mixed with coral, and other hard ſubſtances of that kind. It gives the heat of lime, and the fatneſs of oil, to the land it is laid upon. Being more ſolid than ſhells, it contains a greater quantity of fermenting particles in an equal bulk; nor does it diſſolve into the ground ſo ſoon as ſhells, but decaying more gradually, contines longer to impart its warmth to the juices of the earth.

Similar to this is the practice in Ireland, in that part of the bay of Londonderry, called Loughfoil, towards the eaſtern ſide of which lie ſeveral banks, about the level of low water. They are formed of the ſhells of ſeveral ſorts of ſea fiſh, particularly periwinkles, cockles, limpets, &c. The country people go thither with boats, and take loads of theſe ſhells, which they leave in heaps on the ſhore, till they are well drained, and thereby rendered lighter for farther carriage. They then carry them in boats as far as the river will allow, and afterwards in ſacks on horſes, ſix, ſeven, or more miles up in the country. They allow ſometimes forty, but more commonly eighty barrels to an acre. Theſe ſhells agree with boggy, heathy, clayey, wet, or ſtiff land, but not with ſandy. They ſeem to give the land a ſort of ferment, as yeaſt does to bread, opening and looſening the clods, and by that means making way for the roots to penetrate, and the moiſture to enter into the fibres of the roots. This manure continues ſo long, that the archbiſhop of Dublin, from whom this was communicated to the Royal Society, could not find any perſon able to determine the time of its duration.

The reaſon of its long continuance ſeems to be, that the ſhells melt every year a little, till they are all

ſpent,

ſpent, which requires a conſiderable time; whereas lime, &c. operates, in a manner, at once. But it is to be obſerved, that, in ſix or ſeven years, the ground becomes ſo mellow, that the corn which grows on it cannot ſupport itſelf, and the land muſt be ſuffered to lie a year or two, that the ferment may be a little quieted, and the clods harden; after which it will bear as long again, and continue ſo to do, with the like intermiſſion, for twenty or thirty years.

The good and laſting effects of ſhelly-ſand, for the improvement of clay, afford a ſtrong preſumption that there is an acid in the clay, which the ſhells abſorb or correct: for when that acid is removed, the clay becomes more eaſily ſoluble, or miſcible with water, or, as the farmers term it, is rendered mellow. This is contrary to the opinion of a very ingenious gentleman, Dr. Home, who, becauſe he could not ſeparate an acid from clay, concluded that there was none in it. That the firſt object in the improvement of clay is the deſtroying of this acid, is pretty evident from the qualities of all the ſubſtances uſeful for this purpoſe; every one of them being of the calcarious kind. The tenacity of clay does not ſeem to be owing to the ſmallneſs and unctuous ſmoothneſs of its particles; for in this ſome marles exceed it, and yet are perfectly and eaſily ſoluble in water, probably becauſe they are of a calcarious nature: and if clay be rendered in ſome degree calcarious, by the addition of alcaline or calcarious ſubſtances, ſo long as it continues in that ſtate, it is ſaid to be mellow; that is, it is ſoluble like marle, and continues fit for the production of plants, till the acid in the air either neutralizes the alcali, or ſo far impregnates the calcarious ſubſtances, that they can no longer attract the acid. If this be fact, as it ſeems to be, common ſand can be of little uſe; becauſe the clay will cling as cloſe to a ſtone, or grain of ſand, as it would to part of itſelf, if the ſtone, or ſand, does not ſo far change the body of the clay, as to take off its tenacity; and therefore Dr. Cox ſeems to be very right in ſaying, that the ſand which is formed by the grating of ſtones only, is of little uſe as a manure. However, as ſome eminent writers on this ſubject ſtrongly recommend ſand in general, though they all agree in giving the preference to ſea ſand, it may not be amiſs to hear what they have ſaid on the ſubject.

Columella, ſpeaking in general terms, ſays, that his uncle uſed to carry ſand on clay, and, on the contrary, bring clay on ſandy grounds, with good ſucceſs.

Mr. Worlidge ſays, that the beſt ſand for fertility is that which is waſhed from hills or other ſandy places by the violence of rain; and that ſands which are dry have little fertility in them. *Syſtema Agriculturæ, page* 67.

Mr. Bradley, after dividing ſand into two general ſorts, as Dr. Liſter does, viz. the ſoft, round-grained ſand, ſuch as is found in bogs and hills; and the ſharp or rag-ſand, as it is commonly called, taken from the bottom or rivers, the ſides of high ways, or the ſea; adviſes laying even the former on heavy-ſoils, eſpecially if it happens to be mixed, as it ſometimes is, with rotted vegetable or animal ſubſtances: to which he adds, that its efficacy will be increaſed by the addition of ſand of a ſharper nature, about a load of which laſt if uſed alone, ſhould be ſpread upon every rod of very ſtiff land: for a ſufficient quantity of it muſt be allowed, or elſe the clay will ſoon overcome it. *Complete Body of Huſbandry page* 84.

"The uſe of ſand, ſays Mr. Miller, is to make the clayey earth fertile, and fit to feed vegetables, &c. for earth alone is apt to coaleſce, and gather into a hard coherent maſs, as is apparent in clay; and earth thus glued, as it were, together, is no way diſpoſed to nouriſh vegetables: but if ſand, &c. that is, hard chryſtals, which are not diſſolvable in water, and ſtill retain their figure, be intermixed with ſuch earth, they will keep its pores open, and the ſoil looſe and incompact, by which means the juices will circulate, and plants are nouriſhed thereby. By means of ſand, the earth is rendered, in a manner, organical; pores and interſtices being thereby maintained, ſomewhat analogous to veſſels, by which the juices may be conveyed, prepared, digeſted, circulated, and at length excerned, and thrown off into the roots of plants." *Miller's Gard. Dict.*

Small gritty gravel operates in nearly the ſame manner, as an opener of the earth, and is ſtrongly recommended by Mr. Evelyn, Mr. Worlidge, Mr. Bradley, and Mr. King. Good crops have been produced by very ſtiff and ſour land, after it has been manured with gravel, which, to fit it for this purpoſe, ſhould be ſkreened, or ſifted, ſo as to leave among it as few ſtones as poſſible.

Shell-marle, or any marle, which makes a ſtrong efferveſcence when an acid is dropped upon it, is a particularly good manure for clay; becauſe diſſolving eaſily in water, it gives a ſufficiently free paſſage to this fluid, by which means the clay is kept dry even in winter: and if the ſoil be of a cold ſour nature, the abſorbent quality of the marle deſtroys that mineral acid, and keeps the ground warm.

The foſſile-ſhells which have been found in ſome countries at a great diſtance from the ſea, are a good manure, if they ſtill retain their quality of ſhells: but beſides their being generally petrified, they never are ſo ſerviceable as thoſe which are taken from the ſea-ſhore.

All animal and vegetable ſubſtances are likewiſe proper manures for clay. *See the article* MANURE.

The alcaline quality of the aſhes of all vegetables, and the calcarious quality of coal-aſhes, render them ſingularly beneficial to ſtiff and ſour land, for which purpoſe they are ſucceſsfully uſed in the neighbourhood of ſome great cities where coal is burnt for fuel. They open clayey grounds, and correct their bad qualities. The gardeners and farmers about London know their value, and make a very profitable uſe of them, particularly to bring into order thoſe grounds which have been dug for brick earth. After ſpreading theſe aſhes upon the clay bottom, they either ſow horſe-beans, or ſet the early Spaniſh, or, ſometimes, the Windſor-bean, in thoſe ſpots; or elſe they lay ſuch lands down with rye-graſs, which generally ſucceeds very well. Mr. Bradley, blaming the people of Staffordſhire, and the counties adjoining, where there are coal-pits, for not improving their many heavy grounds around thoſe pits, by manuring them with coal-aſhes, which might eaſily be burned out of the waſte coal, ſays, "That wherever there are plenty of coal-pits, there can be no want of good profitable land." On the ſame principle, we may account for the effects of the calcination of earth, commonly called, burn-baking, or Devonſhiring. *See the article* BURN-BAKING.

Lime, as it is generally uſed, is not found to be of ſo great ſervice in the improvement of clay, as a long eſta-

bliſhed practice might give room to think, or its qualities reaſon to expect; becauſe its particles are ſo extremely ſmall, that when ſeparated, or mixed with the clay, they ſoon become part of its body, and, being ſo much divided, are ſpeedily ſaturated by the acid, either in the clay, or in the air: the beſt method therefore, of uſing lime as a manure for clay is, to ſpread the lime-ſtone unburnt; in which original ſtate acids effervеſce ſtrongly with it, and therefore it will be likely moſt effectually to mellow the clay. It is likewiſe, in this its natural ſtate, attended with the farther advantage of ſaving the expence of burning, and becomes a very laſting manure; nay, probably a perpetual one, if the ſtones are broke into ſmall pieces, which is the proper method of uſing it; as is practiſed at Horneton in Oxfordſhire, where they manure their land with a ſort of ſtone, common in thoſe parts; and about Devonſhire, where a kind of red rock, very tender, and eaſily broken into ſand, is found to be of extraordinary ſervice to clay, or other ſtiff ſoils: for any ſoft ſtone, broken ſmall, will be of advantage to cold lands, if laid upon them. We find by Pliny, that lime was uſed as a manure by the antient Britons, whoſe lands were thereby rendered extremely fertile.

Mr. Evelyn adviſes uſing lime a little ſlacked for cold, wet grounds, and ſtiff clays; and obſerves, that it is apt to over-heat dry ſoils.

Chalk operates in nearly the ſame manner as lime: but, as Mr. Liſle juſtly remarks, if it be laid on clay, it will, in time be loſt, and the ground will return again to its former condition of clay; as we have already mentioned under the article chalk. *See* CHALK.

CLAYEY, mixed with clay, partaking of the nature of clay.

CLAY LANDS, ſuch as partake of the nature of clay. *See the article* CLAY.

The natural produce of clay lands, with regard to weeds, is gooſe-graſs, or wild tanſey, large daiſies, thiſtles, docks, May-weed, poppies, &c.

CLEARING, a term uſed in threſhing corn, to ſignify a heap large enough to winnow.

CLEDGY, ſtiff, ſtubborn, hard, tenacious, mixed with clay.

CLETCH, a brood, as of chickens, &c.

CLOD, a lump of earth or clay.

CLODDING-BEETLE, a large beetle uſed in ſome parts of England for breaking the clods. This operation may be much ſooner performed, and at far leſs expence, by the ſpikey-roller. *See the article* SPIKEY-ROLLER.

CLOVER, the name of a well known plant, and of which there are a great variety of ſpecies; but only three of them cultivated in the open fields for the food of cattle, viz. the red Dutch clover; the white Dutch clover; and the hop-clover.

The firſt ſort is ſufficiently known in England by the name of red clover, and therefore needs no deſcription. It is called by Linnæus, *Trifolium caule erecto, foliolis oblongo-ovatis integerrimis, ſpicis ovatis, calycibus ſetaceis.*

Since red clover has been cultivated in England, great improvements have been made in clay lands, which before produced little except rye-graſs, and other coarſe bents; but, being ſown with red clover, have produced more than ſix times the quantity of fodder they formerly did: whereby the farmers have been enabled to feed a much greater ſtock of cattle, than they could do before, with the ſame extent of ground, which has, at the ſame time, enriched the ſoil, and prepared it for corn; and hence it is now common, where the land is kept in tillage, to lay down their ground with clover, after having had two crops of corn, whereby there is a conſtant rotation of wheat, barley, clover, or turnips, on the ſame land. The clover-ſeed is generally ſown with the barley in the ſpring; and when the barley is taken off, the clover ſpreads and covers the ground; and this remains two years, after which the land is ploughed again for corn.

Clover is a biennial plant, whoſe roots decay after they have produced ſeeds; but by eating it down, or mowing it, when it begins to flower, it cauſes the roots to ſend out new ſhoots, whereby the plant is continued longer than it would naturally do. The common allowance of ſeed for an acre of ground is ten pounds. In the choice of the ſeed, that which is of a bright yellow colour, inclining to brown, ſhould be preferred; and the pale coloured thin ſeed ſhould be rejected. The clover ſeed ſhould be ſown after the barley is harrowed in, otherwiſe it will be buried too deep; and after the ſeeds are ſown, the ground ſhould be rolled, which will preſs the ſeeds into the ground; but this ſhould be done in dry weather, for moiſture will often cauſe the ſeeds to burſt; and when the ground is wet, the ſeeds will ſtick to the roller. The above is the method generally practiſed by moſt people, in ſowing this ſeed with corn: but it will be much better if ſown alone; for the corn prevents the growth of the plants till it is mowed and taken off the ground, ſo that one whole ſeaſon is loſt; and many times, if there be a great crop of corn upon the ground, it ſpoils the clover, ſo that it is hardly worth ſtanding; whereas, when it is ſown without any other ſeed, the plants will come up more equal, and come on much faſter than that which was ſown the ſpring before under corn.

It is therefore adviſable to ſow the ſeed in Auguſt, when there is a proſpect of rain ſoon after; for as the ground is, at that ſeaſon, warm, ſo the firſt ſhower of rain will bring up the plants, and theſe will have time enough to get ſtrength before winter: and if the clover be well rolled ſome time in October, when the ground is not too wet, it will preſs the ground cloſe to the roots, and cauſe the plants to ſend out more ſhoots: the ſame ſhould be repeated in March, which will be found very ſerviceable to the clover. The reaſon for preferring this ſeaſon rather than the ſpring, for ſowing the ſeeds, is, becauſe the ground is cold and wet in ſpring, and if much rain fall after the ſeeds are ſown, they will rot in the ground; and many times when the ſeed is ſown late in the ſpring, if the ſeaſon ſhould prove dry, the ſeeds will not grow. The other ſeaſon is therefore the ſureſt, and conſequently ſhould be preferred.

About the middle of May this graſs will be fit to cut, when the greateſt care ſhould be taken in the making it into hay; for it will require a great deal more labour and time to dry than common graſs, and will ſhrink into leſs compaſs; but if it be not too rank, it will make extraordinary rich food for cattle. The time for cutting is, when it begins to flower; for if it ſtands much longer, the lower part of the ſtems, and the under leaves will begin to dry, whereby it will afford a leſs quantity of hay, and that not ſo well flavoured.

Some people cut three crops in one year of this graſs;

but the beſt way is to cut only one in the ſpring, and feed it the remaining part of the year, whereby the land will be enriched, and the graſs will grow much ſtronger.

One acre of this plant will feed as many cattle as four or five acres of common graſs; but great care ſhould be taken of the cattle when they are firſt put into it, leſt it fill them with wind and kill them, which is called their being hoven. *See the article* HOVEN.

In order to prevent this accident ſome turn them in for a few hours only at firſt, and ſo ſtint them as to quantity; and this by degrees, letting them at firſt feed one hour only in the middle of the day, when there is no moiſture upon the graſs, and ſo every day ſuffer them to remain a longer time, until they are fully ſeaſoned to it: but great care ſhould be taken never to turn them into this food in wet weather; or if they have for ſome time been accuſtomed to this food, it will be at leaſt proper to turn them out at night in wet weather, and let them have hay, which will prevent the bad conſequences of the green clover. Others give their cattle ſtraw while they are feeding upon this graſs, to prevent the ill effects of it; but this muſt not be given them in the field, becauſe they will not eat it, where there is plenty of better food. There are others who ſow rye-graſs among their clover, which they let grow together, in order to prevent the ill conſequences of the cattle feeding wholly on clover; but this is not a commendable method, becauſe the rye-graſs will greatly injure the clover in its growth, and the ſeeds will ſcatter, and fill the ground with bent.

When the ſeeds are intended to be ſaved, the firſt crop in the ſpring ſhould be permitted to ſtand until the ſeeds are ripe, which may be known by the ſtalks and heads changing to a brown colour, when it ſhould be cut in a dry time; and after being well dried, it may be houſed till winter, when the ſeeds ſhould be threſhed out; but if the ſeeds are wanted for immediate ſowing, it may be threſhed before it be houſed or ſtacked; but it muſt then be well dried in the field, otherwiſe the ſeeds will not quit their huſks.

It has been a common complaint among the farmers, that they could not threſh out theſe ſeeds, without great labour and difficulty; but this is chiefly owing to their cutting their ſpring crop, when it begins to flower, and leave the ſecond crop for ſeed; which ripening ſo late in autumn, there is not heat enough to dry the huſks ſufficiently; whereby they are tough, and the ſeeds rendered difficult to get out. This complaint may therefore be entirely removed by leaving the firſt crop for ſeed, as above directed; and then the ground will be ready to plough and prepare for wheat the ſame year, which is another advantage.

When cattle are fed with this hay, the beſt way is to put it in racks, otherwiſe they will tread a great deal of it down with their feet. This ſeed is better for moſt other cattle than milch cows, ſo that theſe ſhould have very little of it, leſt it ſhould prove hurtful to them; though it is not near ſo injurious to any ſort of cattle when dry, as it is when green.

The ſecond ſort, namely, the white Dutch clover, grows naturally in moſt of the paſtures in England, and is generally known among the country people, by the name of white honey-ſuckle. Linnæus calls it, *Trifolium capitulis umbellaribus leguminibus tetraſpermis, caule repente.*

This is an abiding plant, whoſe branches trail upon the ground, and ſend out roots from every joint, ſo that it thickens and makes the cloſeſt ſward of any of the ſown graſſes; and it is the ſweeteſt ſeed for all ſorts of cattle yet known: therefore when land is deſigned to be laid down for paſture, with intent to continue ſo, it ſhould be ſown with the ſeeds of this plant. The uſual allowance of this ſeed is eight pounds to one acre of land; but this ſhould never be ſown with corn, for if there is a crop of corn, the graſs will be ſo weak under it, as to be ſcarce worth ſtanding; but ſuch is the covetouſneſs of moſt farmers, that they will not be prevailed on to alter their old cuſtom of laying down their grounds with a crop of corn, though they loſe twice the value of their corn by the poorneſs of the graſs, which will never come to a good ſward, and one whole ſeaſon is alſo loſt; for if this ſeed is ſown in the ſpring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than the graſs which is ſown with corn will produce the ſecond year. The ſeed of this ſort may alſo be ſown in autumn, in the manner before directed for the common red clover; and this autumnal ſowing, if the ſeeds grow kindly, will afford a good early crop of hay the following ſpring; and if, after the hay is taken off the land, the ground be well rolled, it will cauſe the clover to mat cloſe upon the ground, and become a thick ſward.

The ſeeds of this white Dutch clover is annually imported from Flanders, by way of Holland, whence it received the name of Dutch clover: not that it is more a native of that country than of this, for it is very common in moiſt paſtures, in every county in England: but the ſeeds were never collected for ſowing in this country, till of late years; nor are there many perſons here, even now, who ſave this ſeed; though it may be done if the ſame method, as is practiſed for the red clover, be taken with this ſort: it ſhould therefore be recommended to every farmer, who is deſirous of improving his land, to ſow carefully an acre or two of this white clover for ſeed, which will ſave him the expence of buying for ſome years, when the price is great; and there will be a ſure market for any quantity he may have to ſpare.

The reader will find a farther account of this graſs under the article PASTURE.

The third ſort, namely hop-clover, called by ſome yellow meadow trefoil, and by botaniſts, *Trifolium ſpicis ovalibus imbricatis, vexillis deflexis perſiſtentibus, calycibus nudis, caule erecto*, grows naturally among the graſs in the upland paſtures of this country; but the ſeeds are frequently ſold in the ſhops, and are by many mixed with the other ſorts of clover and graſs-ſeeds, for laying down ground to paſture. This plant grows with upright branching ſtalks about a foot high, garniſhed with trifoliate leaves, whoſe lobes are oblong and heart-ſhaped, but reverſed, the narrow point joining the foot-ſtalks. The flowers, which are yellow, grow from the wings of the ſtalk, upon long foot-ſtalks, collected into oval imbricated heads, having naked impalements lying over each other like ſcales, ſomewhat like the flowers of hops, from whence the plant had the name of hop-clover. But there are two ſorts of this clover, which grow naturally in England. The other is a much ſmaller plant than this,

and

and generally known by the name of noneſuch, or yellow hop-treſoil. *See the article* NONESUCH.

The hop-clover is ſtrongly recommended by the following circumſtances. 1. It not only grows, but flouriſhes on the moſt barren ſands, and therefore muſt be a very proper graſs to cultivate on ſuch unfertile ſoils, where any other graſs that is worth notice will not grow at all. 2. It is not apt to ſwell cattle, as the red clover does. 3. In good ground it will continue long, and bear a very good ſeed or crop, as Mr. Tull, though prejudiced againſt clovers, confeſſes; and, by its flouriſhing both on ſands and clay, which have not been ploughed for many years, it ſeems likely to continue long in any ſoil.

CLOUGH, a valley between two ſteep hills. It alſo ſignifies a cliff.

CLOUT, an iron plate on the axle-tree of a carriage.

CLUMP, a number of trees growing together without ſhape or order.

CLUNG, cloſed up, or ſtopped; ſpoken of hens when they do not lay. It is alſo applied to wood, or any other thing that is ſhrivelled, or ſhrunk up, when it is ſaid to be clung.

CLUSTER, a bunch, a number of things of the ſame kind growing or joined together. Alſo a number of animals, or a body of people, collected together.

M. de Chateauvieux has made a very remarkable experiment on ſowing corn in cluſters, which muſt not be omitted here.

"It is of great conſequence, ſays that ingenious and aſſiduous cultivator, to know which is the moſt profitable way of ſowing beds with corn; I mean, that by which they will be ſtocked with a proper number of plants; for when too much ſeed is ſown, the plants hurt one another; and when too little, the earth is not enabled to produce ſo much as it is capable of doing.

"The buſineſs, therefore is to determine what number of plants would be moſt advantageous. Luckily the difference is wide enough between the too great, and the too ſmall number; and the produce of the crop cannot only be diminiſhed by an exceſs one way or the other.

"But whatever certainty we may acquire with reſpect to this intereſting point, we cannot flatter ourſelves that we ſhall be always able to keep it in our practice. The various accidents to which corn is liable, from the hour of its being ſown till it is reaped, will always fruſtrate the methodical arrangement which we may have intended to give the plants.

"The difficulty of ſucceeding in this enquiry ought not however to diſcourage us: for it would be attended with ſuch advantages, as would make very ample amends for all the labour beſtowed upon it. Let us then have recourſe to experiments. Thoſe that are made with this view can never be quite uſeleſs. If they do not lead us to the very thing we are in ſearch of, they may at leaſt diſcover to others what may be of ſervice.

"According to our principles, the diſtance between each plant ought to be equal throughout the whole length of the rows, that all of them may have an equal quantity of earth to draw their nouriſhment from.

"Several experiments have ſhewn, that ſix inches is not too great a diſtance for the plants to be at from one another. In this caſe it would be ſufficient to ſow one grain of wheat at every ſix inches diſtance. According to this diſpoſition, a field well prepared ought to produce the greateſt crop. The plants will commonly branch out ſo as to have twenty, thirty, or forty ſtalks: I have had ſome with upwards of eighty. It is pity that this exact diſtribution of the ſeed cannot ſubſiſt long. An accident I lately met with ſoon convinced me that it was neceſſary to increaſe the quantity of ſeed, and that very conſiderably.

"This does not, however, yet hinder me from thinking, that if any eaſy method could be found to have a plant of wheat exactly at every ſix inches diſtance in the rows, it would be the beſt way of ſowing lands. I have often conſidered how this could be reduced to practice, as well to ſatisfy my curioſity, as to enable me to proceed with more certainty in my operations. When a theory is known to be good, we are ſtrongly encouraged to draw all poſſible advantages from it for the practical part; we proceed with confidence and pleaſure.

"Experience having convinced me that it never would be poſſible to have a plant at every ſix inches in each row, by ſowing only a ſingle grain of wheat at thoſe diſtances, it naturally followed, that the way to have the ground better covered with plants was, to ſow more grains. The next queſtion was, how many grains ſhould or ought to be ſown in each place? Should it be two, three, or more? Experience only could anſwer this queſtion. I therefore tried the following experiment. I ſowed a different number of grains in cluſters, ſix inches diſtant from each other, putting one grain in the firſt, two in the ſecond, and ſo on to the ſixth, which had ſix grains: then I began again, and went on as before, till the whole length of the row was ſowed in this manner. The produce of each cluſter was to ſhew me whether it would be beſt to double, triple, or quadruple the ſeed, which it was plain had been ſown too thin, when a ſingle grain was dropt at every ſix inches.

"The winter of 1753 was already far advanced when theſe thoughts firſt occurred to me. It was then too late to try this experiment with wheat; but that I might not loſe a year, I did it in the ſpring with barley; not doubting but that corn, which is uſually ſown in March, might furniſh me with ſome future hints for the culture of that which remains longer in the ground.

"Accordingly on the ninth of April 1754, I ordered another bed to be ſowed with barley in my preſence, and in the manner I have juſt related. I counted all the grains of each cluſter myſelf. They were ſown in three rows. I varied the experiment in the rows next the ſouth, by ſowing no cluſters there of leſs than three, four, five, or ſix grains: which I continued the whole length of the row. At harveſt, all the cluſters in which ſeveral grains had been ſowed, were ſo thick, that they touched one another.

"What is of moſt conſequence to our culture is, to know the produce of each cluſter. But it will be neceſſary previouſly to obſerve, that the cluſters were ſown in rows extending forty feet in length, and that the beds were five feet wide.

"Reſults:

The *South row.*

ſowed with 6, 5, 4, and 3 grains,
produced 661, 624, 447, and 493 ſtalks.
In all 2225 ſtalks.

" *The Middle row,*

ſowed with 1, 2, 3, 4, 5, and 6 grains,
produce 48, 72, 147, 204, 219, and 487 ſtalks.
In all 1177 ſtalks.

" *The North row,*

ſowed with 6, 5, 4, 3, 2, and 1 grain,
produce 502, 372, 345, 276, 200, and 92 ſtalks.
In all 1787 ſtalks.

" Conſequently the whole number of ſtalks in the three rows was 5189. They yielded ſeventeen pounds of grain, beſides a very conſiderable quantity ſhed in cutting.

" On the footing of this crop, an arpent of thirty-ſeven ſquare toiſes (equal to about one acre and three quarters of a rood Engliſh) would contain at leaſt forty-four beds five feet wide, which was the breadth of the beds on which this experiment was made. The beds would be 222 feet long: the produce of one of them would be ninety-three pounds, eight ounces; and that of the forty-four, 4138 pounds, eight ounces; a very conſiderable crop, and which might be carried ſtill further by other experiments of the ſame kind.

" The following obſervations deſerve the reader's utmoſt attention. Firſt, by this experiment, I have very nearly effected what I aimed at, viz. to have two or more plants grow ſo cloſe together, as to ſeem but one; and that at ſix inches diſtance from each other. If the three rows had been joined together lengthways, they would have been 120 feet long, and ought to have contained 240 plants only: but the diſtances, which were marked by gueſs, not being exactly ſix inches each, ninety-ſix cluſters were ſown in each row, which made ſixteen cluſters over and above. By this means ſeveral of them were nearer than ſix inches to one another.

" Two hundred and eighty-eight cluſters were ſown, all of which produced plants, except twenty-five, which either did not ſprout, or the plants periſhed. This deficiency is not very conſiderable; but we muſt obſerve, 1. That almoſt all the places where this happened had been ſown with only one or two grains of corn. 2. That it was in the middle row that the greateſt number of plants was wanting. 3. That the ſouth row, in which the ſmalleſt quantity ſown for any one tuft, was three grains, furniſhed and retained its full number of plants: and laſtly, that almoſt all thoſe which were next to the vacant ſpaces, were ſtronger than the reſt, and thereby made amends for the loſs of the others.

" Secondly, the whole number of the ſtalks amounted to 5189, which is after the rate of forty-three ſtalks and a quarter to a foot: but it is much more conſiderable in the ſouth row, which having produced in all 2225 ſtalks, the proportion is fifty-five and a half to a foot. The cauſe of this difference is eaſily ſeen. The expoſition of that row to the ſouth being more favourable than that of the others, may have contributed thereto; but it was very plain that it was chiefly owing to none of the cluſters in that row being ſown with ſo few as one or two grains.

" Thirdly, we ſee that the increaſe of the ſtalks was, in general, in proportion to that of the ſeed; only the cluſters that were ſown in three grains in the ſouth row, produced forty-ſix ſtalks more than thoſe which were ſown with four grains; but ſtill the general reſult of the three rows was exactly in the ſame progreſſion, as appears by the following recapitulation:

RECAPITULATION.

Stalks produced by 1 grain - - - - -	140
2 gr. - - - - -	272
3 gr. - - - - - -	916
4 gr. - - - - - -	996
5 gr. - - - - -	1215
6 gr. - - - - -	1650
Total	5189

" Fourthly, the ears were nearly equal, at leaſt in two thirds of the length of the rows: the other third ſurpaſſed the reſt very conſiderably.

" Fifthly, the difference between the produce of the cluſters ſowed with one, and with ſix grains, is extremely great. The former produced but 140 ſtalks, the other multiplied to 1650. It is true the number of the cluſters of ſix grains is greateſt, which is ſome ſmall diminution of this difference.

" Sixthly, I obſerved ſeveral ſtalks from which others had ſhot out, all as ſtrong, and as long, as thoſe from which they derived their origin. They proceeded from the firſt joint above the ſurface of the earth, generally at the height of three, four, or five inches, and were two, three, and ſometimes four in number. I never perceived this kind of multiplication before; but had till then always obſerved it to be at the neck, or point of ſeparation between the roots which deſcend, and the ſtalks which aſcend, that the ſtalks branched out.

" Seventhly, I ſuſpected, in the ſummer, what was the cauſe of the great vigour of the plants of this experiment; but I ſaw it much plainer after harveſt: for, upon pulling up ſome of the tufts of ſtubble, I found their roots innumerable. This fact is ſtrictly true. I could not count them upon any one plant that had more than fifteen or twenty ſtalks. Theſe roots were in ſuch bundles, and ſo confuſedly interwoven one with another, that after counting ſeveral hundreds of them I was forced to give up the taſk. Their length and thickneſs was anſwerable to their number.

" I muſt now remind the reader of what I ſaid before, that the ſeveral accidents which I met with in my firſt experiments, ſhewed me it was neceſſary to increaſe the quantity of the ſeed. I did ſo, by ſmall degrees, from year to year. It is equally important for the ſucceſs of the New Huſbandry, not to run into another extreme, by loading the earth with more plants than it can nouriſh: the crop would be conſiderably diminiſhed thereby.

" It appears from this experiment, that the plants of the cluſters that were ſowed with ſix grains, did not hurt one another: on the contrary, their being ſown in that manner proved an advantage, ſince they produced much more than the others; whence it follows, that we may, without danger, extend the quantity of ſeed beyond the limits of the New Huſbandry. Its principles are not the leſs true; but they leave the farmer at liberty to uſe his own prudence in the application of them, according to the nature of the ſoil.

" Thoſe principles, which ſuppoſe that every plant is

to ſubſiſt till harveſt, reduce the ſeed to a very ſmall quantity: but numbers of accidents deſtroy many of them. Our reaſon ought therefore to tell us, that without deviating too much from the principles we adopt, we may, and ſhould, judiciouſly ſtock our land with a ſufficient number of plants, in order to guard againſt unavoidable accidents.

"Still I may be aſked, what is the ſufficient quantity? I anſwer, that our experiment ſhews that ſowing ſix grains together in a cluſter, at the diſtance of ſix inches from each other, all the length of the rows, will not be found too thick. By following this rule, we may be almoſt certain that the whole ground will be ſtocked with a proper number of plants. This ought, however, to be looked upon only as a general propoſition, which it will be often proper to deviate from in the circumſtances we are going to mention.

"When the ſowing ſeaſon is favourable.

"When the land is well prepared.

"In countries where the winter is ſeldom ſevere.

"When the land is but little liable to inſects.

"When the land is not in danger of being hurt by too much drought, or too much wet.

"And laſtly,

"When the land is good, and very fertile.

"In all theſe and ſuch like caſes, leſs ſeed ſhould be ſowed; and, in the contrary caſes, more. Prudence, and a careful ſtudy of the nature of the ſoil, ought to be our guides. Two or three years experience will be ſufficient to ſhew us the practice that will be beſt to follow.

"It will be right to repeat our laſt mentioned experiment, and even to vary it. In all probability it will afford us ſtill greater lights. It will be right, for example, to ſow the cluſters with a greater number of grains, beginning with ſix, the produce of which is known, and going on to ſeven, eight, or even more, always in cluſters, till we come to a number at which the crop ceaſes to yield an equal profit. By this means the two extremes may be known, either of too much, or too little ſeed; and the juſt proportion will then be eaſily determined.

"Some farther alterations may likewiſe be made in this experiment. For example, I placed the grains in the earth ſo that they touched one another; they may be placed at ſome little diſtance, and ranged in a kind of circle of about three inches diameter. It is reaſonable to think, that the plants may then make a greater progreſs, as they will not all have one common center: ſome of them will be nearer the ploughed alley; their roots will reach it more eaſily than before, and will multiply there; which may render the plants more vigorous." *Du Hamel's Culture des Terres, tom.* IV.

CLUSTER-GRAPE, the ſmall black grape, generally called the currant.

COAL, the common foſſile fuel.

COAL-ASHES. *See the article Coal-*ASHES.

COAL-BALLS, a compoſition of culm, or the duſt and refuge of pit-coal, mixed up with mud, clay, &c. burnt as fuel.

About Briſtol, Briſlington, and other places in the weſt of England, they commonly make coal-balls of their culm, or ſmall refuſe-coal, which would not otherwiſe be ſaleable.

The method of making theſe balls is, to take a certain quantity of the culm, and an equal quantity of fleech, or mud left by the tide on the ſea-ſhore: theſe ingredients are firſt mixed groſsly with ſhovels, and then blended more perfectly with the hand: after which they are moulded into balls of about ſix inches diameter.

Theſe balls may either be burnt immediately as ſoon as they are made, or laid up and kept as long as the owner pleaſes, without ſuffering the leaſt damage.

The inhabitants of Croken-pill, near King Road, about ſeven miles below Briſtol, are ſuppoſed to make them in the greateſt perfection. They ſeldom uſe any other fuel, and find it anſwers extremely well, being much cheaper than coal, making as good a fire, and laſting longer. They make it a rule to work as much culm into the fleech with their hands, when they mould the balls, as they poſſibly can, without making them crumbly.

Theſe balls have not been uſed above thirty or forty years in the above parts; but are now greatly preferred, though they can have coals laid in at three-pence halfpenny the buſhel.

In Wales, where theſe coal-balls are alſo made, they uſe clay inſtead of the fleech, allowing two parts of culm to one of clay, adding to the heap a ſufficient quantity of water, which they temper with it, in the ſame manner as if they were making mortar mith lime and ſand. And after the culm and clay have been ſufficiently mixed and tempered together, they form the whole into balls, in the manner above related.

The balls made with clay are not ſo pleaſant a fuel as thoſe made about Briſtol with fleech, becauſe the clay is apt to emit a ſtinking ſmoke, eſpecially if the balls are burnt before they are dry: but notwithſtanding this inconvenience, which the lower ſort of people little regard, they afford the poor a good and cheap fuel.

It is ſurprizing that ſome work of this kind is not undertaken in the neighbourhood of London, as it would greatly tend to leſſen the enormous expence to which the poor of the metropolis are every winter ſubject, for fuel; and could not fail of rewarding the undertaker for his trouble. Culm might be imported into the Thames very cheap, and nothing could be more ſuitable than the river mud to mix with it, in order to form the balls; it would, probably, do better than the fleech, being of a richer, and more combuſtible nature.

COAL-SOOT, the ſoot collected in chimnies, &c, where coals are burnt. A correſpondent of the editors of the Muſeum Ruſticum has obliged the world with ſome uſeful obſervations on coal-ſoot as a manure. He obſerves that many farmers in ſome countries are at a great loſs to find a proper dreſſing for their meadows; and to ſuch he recommends the uſe of coal-ſoot, as highly profitable and advantageous; its effects will be very viſible for upwards of three years, during which time no other manure need be laid on the land.

"Coal-ſoot, ſays he, is of a very warm refreſhing nature: it cheriſhes, and gives nouriſhment to the graſs; it kills the noxious inſects that infeſt the crop, and protects it from the effects of froſts, ſnows, and chilling rains; and, what is ſtill of greater conſequence, it will kill the moſs that often abounds in ſour meadows.

"I muſt not however fail noticing, that ſoot will not have theſe good effects if the meadow-land ſhould be ſo damp as to require draining: in this caſe, cuts muſt be made acroſs it, in proper directions, previous to the laying on the coal-ſoot, which would otherwiſe be of little ſervice.

"All

" All rank weeds ſhould be carefully grubbed up from among the graſs, and that before they have perfected their ſeeds; without which precaution, in point of time, the work would be to do over again.

" The general quantity I lay on an acre of meadow-land is twenty-five looſe buſhels: more I find to be rather prejudicial, and leſs does not anſwer all the purpoſes we are to expect from this excellent manure.

" The beſt time for applying this dreſſing, I take to be the beginning of the ſpring: about February is the time I generally lay it on; the gentle rains which then, for the moſt part, enſue, waſh it into the land, and the following crop is greatly benefited by it. This is very ſoon viſible from the fine deep verdure which the graſs aſſumes.

" Some of my meadow-land is particularly ſubject to be damaged by froſts, ſnows, &c. on this I generally lay the proper quantity of ſoot in the beginning of November; and ſometimes, if the winter is likely to be ſevere, I venture to allow thirty buſhels to an acre, which in other caſes I never do.

" Having myſelf found great benefit by uſing this coal-ſoot as a manure for meadows, I am willing my brother farmers ſhould know it, that they may have it in their power to adopt the practice, if they approve of it.

" It will be well worth their while, provided they can have it at a reaſonable rate, which they may, if they do not live more than twenty miles from London, by land-carriage, and wherever there is a communication by water, though at almoſt ever ſo great a diſtance.

" Other great towns alſo, where ſea or pit-coal is burnt, may ſupply the farmers with it; but the misfortune is, that where it is in the greateſt plenty, they leaſt know the uſe of it.

" Great care however ſhould be taken to get it genuine and good, the merchant chimney-ſweepers, frequently to increaſe the bulk, mixing the fine ſifted coal-aſhes with it: this is a great fraud, but may eaſily enough, with proper care and circumſpection, be diſcovered; for the aſhes make the ſoot gritty, and increaſe its weight in a very ſenſible degree.

" Before I conclude, I muſt give my brother farmers a caution; which is, that they never lay the ſoot on their land in windy weather, as not only great part of it will be loſt and waſted, but the remainder will be ſo unequally diſpoſed, as to do rather more harm than good." *Muſeum Ruſticum, vol.* I. *pag.* 218.

Coal-ſoot is alſo an excellent dreſſing for green wheat in February; it ſhould be ſown by hand, in quantity ſufficient to blacken the ground. This is frequently practiſed in Leiceſterſhire, and many other counties. It is of a warm nature, and therefore does moſt good on cold, moiſt, clayey ſoils.

COB, a wicker baſket to carry on the arm. Hence a ſeed-cob, or ſeed-lip, is a baſket for ſowing.

COCCIFEROUS *Plants*, ſuch as bear berries.

COCK, the male of the hen; alſo the male of any ſmall birds.

COCKEREL, a young cock.

COCKLE, the ſame with darnel-graſs. *See* DARNEL-GRASS.

CODLING, a well known ſpecies of apple. *See the article* APPLE.

COFFIN, that part of the horn or hoof of a horſe which appears when he has his foot ſet on the ground.

COFFIN-BONE, that bone which lies within a horſe's hoof as in a coffin.

This bone is round upwards, where it receives the little paſtern, but grows broader and thinner towards its bottom; it is of a porous open contexture, like a piece of loaf ſugar, and is eaſily pierced, and often wounded when horſes happen to take up nails or other ſharp bodies in the ſtreets or roads: accidents to which they are often liable, and are more eaſily cured than they would have been, had the bone been hard and ſolid.

COFFIN-JOINT, that where the leſſer paſtern joins the foot.

When the coffin-joint is ſtrained, a horſe often continues a long time lame, without the owner's diſcovering where the lameneſs lies; becauſe a horſe does not, at firſt, favour it much on the bending of the foot, only in planting his foot upon the ground: but in time there will grow ſuch a ſtiffneſs in that joint, that he will only touch the ground with his toe, and it will be impoſſible to play the joint with one's hand. The only method of removing this ſtiffneſs is bliſtering and firing, which generally ſucceeds, unleſs the ſtiffneſs and contraction has been of long ſtanding. *Gibſon's Farriery, vol.* II. *pag.* 372.

COKE, pit-coal, or ſea-coal, charred. It is made by burning pit-coal in ovens conſtructed for that purpoſe, and extingiuſhing the fire in the ſame manner as is done for charcoal.

COLD, the name of a diſeaſe to which animals of almoſt every kind, particularly horſes, are very ſubject.

Colds are cauſed by an obſtruction of perſpiration: that is, the pores, or outlets of the ſkin, are ſo far ſhut up, that the ſteams of perſpirable matter are checked ſo that they cannot paſs off in their uſual manner. The conſequence of this is, they recoil on the blood, vitiate its quality, overfil the veſſels, and affect the head, the glands or kernels of the neck and throat, the lungs, and other principal parts.

It would be endleſs to enumerate the various cauſes of colds; the moſt uſual are, riding horſes till they are hot, and ſuffering them to ſtand in that condition, where the air is cold and piercing; removing a horſe from a hot ſtable to a cold one, and too ſuddenly changing his cloathing; hence it is that horſes catch ſevere colds after they come out of dealer's hands; and by not being carefully rubbed down, when they come in hot, off journeys.

The ſigns of a horſe's catching cold, are a cough, heavineſs, and dullneſs, which affect him more or leſs in proportion to the ſeverity of it; the eyes are ſometimes moiſt and watery, and the kernels about the ears, and under the jaws ſwell, the noſe gleets, and he rattles in his breathing; and when the cold is violent, the horſe will be feveriſh, his flanks work, and he will both loath his hot-meat, and refuſe his water. When theſe laſt ſymptoms are attended with a ſlimy mouth, ears and feet cold, and a great inward foreneſs, there is danger of a bad fever.

But when the horſe coughs ſtrong, ſnorts after it, is but little off his ſtomach, pricks up his ears, and moves briſkly, in his ſtall, dungs and ſtales freely, his ſkin feels kindly, and his coat does not ſtare, he is in no danger, and there will be no occaſion for medicines of any kind; but you ſhould bleed him about two quarts, keep him warm, and give him ſeeds of ſcalded bran, with as much

warm

warm water as he will drink, in order to dilute his blood.

If the diſorder ſhould increaſe, the horſe fall hot, and refuſe his meat, bleed him, if a ſtrong one, two quarts more; and if you are not ſatisfied, without giving medicines, avoid, as you would poiſon, a farrier's drench; which is generally compoſed of ſome hot nauſeous powders, given in a quantity of ale: which too often increaſes the fever, by over-heating the blood, and palls the horſe's ſtomach by its loathſomeneſs. And inſtead of it, infuſe two ounces of anniſeeds, with a dram of ſaffron, in a pint and a half of boiling water; pour off the clear, and diſſolve in it four ounces of honey; to which may be added four ſpoonfuls of ſallad oil: this drink may be given every night; or one of the following balls, provided there is no fever; in which caſe, it always will be more eligible to give two or three ounces of nitre, or ſal prunella, every day in his feeds, or water, till it is removed; but ſhould the horſe be inclined to coſtiveneſs, remember that his body ſhould be kept open by emollient clyſters, or cream of tartar diſſolved in his water, to the quantity of three or four ounces a day.

Take of the freſh powders of anniſeed, elicampane, carraway, liquorice, turmeric, and flour of brimſtone, each three ounces; juice of liquorice four ounces, diſſolved in a ſufficient quantity of mountain; ſaffron powdered half an ounce, ſallad-oil and honey each half a pound, oil of anniſeed one ounce; mixed together with wheat-flour enough to make them into a paſte.

Or, Take the following from Dr. Brachen.

Take anniſeed, carraway-ſeed, and greater cardamoms, finely powdered, of each one ounce, flour of brimſtone two ounces, turmeric in fine powder one ounce and a half, ſaffron two drams, Spaniſh juice diſſolved in water, two ounces, oil of anniſeed half an ounce, liquorice-powder one ounce and a half, wheat-flour, a ſufficient quantity, to make into a ſtiff paſte, by beating all the ingredients well in a mortar.

Theſe balls conſiſt of warm opening ingredients; and, given in ſmall quantities, about the ſize of a pullet's egg, will encourage a free perſpiration; but, in caſe of a fever, ſhould be cautiouſly continued. They are much more efficacious, and in all caſes ſuperior to the farrier's drenches, if diſſolved in a pint of warm ale.

This ſimple method, with good nurſing and hot maſhes, warm water and cloathing, eſpecially about the head and throat, which promotes the running at the noſtrils, will anſwer in moſt ſudden colds; and when the horſe feeds heartily, and ſnorts after coughing, moderate exerciſe every day will haſten his recovery.

The ſcalded bran ſhould be put hot into the manger, for the ſteams conduce not a little to promote a running at the noſe, which is often very plentiful, and greatly forwards the cure. His manger ſhould be kept clean, by filling it with ſtraw; his hay well ſhook and ſprinkled with water, and given in ſmall quantities: for his breathing, at this time, taints the hay, and then he will not touch it.

To a horſe loaded with fleſh, a rowel may ſometimes be neceſſary, as may alſo a gentle purge or two, to ſome, when the diſtemper is gone off. *Bartlet's Farriery, pag.* 26.

COLD-CHARGE, the name of a medicine much uſed by farriers for curing ſtrains, &c. It conſiſts of vinegar, bole, and the whites of eggs, mixed together to the conſiſtence of a poultice, and ſpread over the part hurt.

COLE, *or* RAPE, the name of a plant greatly cultivated, both on account of its ſeed, being that from whence the rape-oil is drawn; and alſo for feeding cattle. The botaniſts call it *napus ſylveſtris*, or wild navew.

The marquis de Turbilli, who has done more ſervice to agriculture than any other foreign writer, has lately publiſhed a memoire on the culture of cole-ſeed, as practiſed by the Flemiſh farmers, to whom we are indebted for many valuable improvements in huſbandry.

In the piece above-mentioned, the marquis obſerves, that all ſorts of cole-ſeed are cultivated in the ſame manner; and that all grow more or leſs towards their natural perfection, yield more or leſs ſeed, and this ſeed is of a better or worſe quality, according to the nature of the ſoil on which the cole-ſeed is ſown, the good or bad huſbandry beſtowed on it, the favourableneſs of the ſeaſon, and the manner in which it eſcapes other accidents to which it is ſubject.

Cole-ſeed, he ſays, thrives beſt in deep kindly ſoils; but with plenty of manure, and deep ploughing, it will grow any where. He adds, that he has ſeen it yield good crops on a dry chalky ſoil, on which ſtreet dirt had been laid.

We muſt obſerve, that this is a very uſeful piece of knowledge to propagate, as we never yet heard of any farmer in England, who ventured to ſow it on ſuch a ſoil. This ſhould be attended to by the Bedfordſhire farmers about Dunſtable, &c.

Our noble huſbandman next remarks, that in Flanders cole-ſeed is ſown and tranſplanted like cabbages: they give two ploughings to the land before winter; and it is not of much conſequence what crop the land was laſt under.

In the month of May another deep ploughing is given; the land is harrowed two or three times, and then rolled, in order to make it fine. Towards the eighteenth or twenty-fourth of July, it is again ploughed, harrowed, and rolled till it is reduced to as fine a tilth as poſſible: the ſeed is then ſown, being ſcattered by the three fingers: the land is lightly harrowed, and afterwards rolled.

The marquis ſays, that twenty-four pounds of ſeed will ſow three acres, and the plants on theſe three acres will fill twelve others. Cole-ſeed is tranſplanted after any crop whatever.

The land intended to receive the cole-ſeed plants ſhould be twice ploughed as ſoon as the crop is carried off. About ten or fifteen days afterwards it is to be once or twice harrowed, and towards the end of September it ſhould have a very deep ploughing. In this laſt ploughing there ſhould be an open furrow or trench every five bouts. If the field does not lie level, it ſhould be ploughed obliquely, ſo that there may be an eaſy fall for the water.

The beſt and moſt promiſing plants being taken up, and tied in bunches, are carried to the field where they are to be tranſplanted, by the time the laſt ploughing is completed, and the workmen are ready for them.

There will always remain a number of plants in the land where they were ſown: theſe are generally fed off with cattle; for the farmers never let them ſtand to ripen their

their ſeeds, unleſs they intend to manure the land for the ſucceeding crop.

The ſeaſon in Flanders for tranſplanting cole-ſeed is the beginning of October. The plants are placed in rows acroſs the furrows. The rows are one foot aſunder, and the plants in the rows about ſix inches diſtance one from the other. The manner in which this work is idone is as follows. A certain number of men advance n a parallel line, each having a dibble, or ſpade-handle, with two large iron points to it, ſix inches aſunder: they drive this inſtrument into the ground; the women and children follow, who put a plant into every hole, and ſettle it at the ſame time; which is eaſy enough to do, and it ſaves ſome expence.

When all the cole-ſeed is planted, if the land to which it was removed was not dunged before it was ploughed, it muſt be ſown with pigeons dung reduced to powder: this, of all other manures whatever, has the moſt immediate and proper effect on the vegetation of this plant; ſixty buſhels are enough for two acres.

When this is done, the looſe earth in the trenches, or open furrows, is to be thrown with a ſhovel amongſt the plants in the rows. Early in the ſpring, a ſpit of earth out of the trenches is, in like manner, to be caſt amongſt the plants of cole-ſeed in the rows. This ſlight tillage gives vigour to the crop, choaks the weeds, and keeps the ſoil looſe.

The rows of cole-ſeed form a number of beds, and when it thrives well, the trenches are entirely covered, and the whole reſembles a thick copſe.

Here the marquis obſerves that cole-ſeed thrives perfectly well in new-encloſed lands.

The ſeed is fit to gather about the beginning of July. When it turns yellow, it is reaped like corn, and laid in pretty large gavels on the beds, where it remains three or four days; it is then carried in cloths, in order to prevent any of the ſeed from being loſt, for it is very ready to drop.

In one, or ſeveral parts of the field, in proportion to its extent, and to the quantity of cole-ſeed there is, the crop is formed into ſeveral ſtacks. The Flemiſh farmers never thatch theſe ſtacks; they know ſo well how to make them, that the rain does them no damage. The cole-ſeed heats in the mow, by that means yielding more oil than it would have done, if it had not been ſtacked.

In the month of September they make a kind of floor in the field, whereon they threſh and dreſs their cole-ſeed. If a farmer ſhould incline to threſh his cole-ſeed without ſtacking, it will be neceſſary for him to leave the gavels longer expoſed to the air on the beds. Cole-ſeed may be cut at any time of the day, provided it does not ſhed; if it does, it ſhould only be cut mornings and evenings. As a whole field does not all ripen at the ſame time, it ſhould be cut in different portions; being laid in gavels, or heaps, the changes of weather will not affect it. It may ſafely be ſtacked three or four hours after rain, provided it has previouſly been ſome time in gavels, and is judged ſufficiently dry.

In order to clean the ſeed, parchment ſieves are uſed, if there is any wind ſtirring; but if it be calm, they uſe wind-fans.

Cole-ſeed ſhould not be ſown on the ſame land above once in five or ſix years.

In the neighbourhood of Clermont, in Beauvoiſis, the marquis tells us, that they let the cole-ſeed ripen in the field where it was firſt ſown; but if they conſidered that cole-ſeed is not fond of moiſture, that it ſends forth large roots into the earth, and grows to a great height, with numerous wide extended branches, they would be ſenſible that the land, being covered with too many plants, muſt be impoveriſhed; and that plants, which ſtand ſo cloſe together, cannot attain their full ſize: thus, in this way, the land is impoveriſhed, the weeds are left to perfect and ſhed their ſeeds in it, and not only the crop of cole-ſeed is very indifferent, but alſo the crops which ſucceed it. In order to reſtore ſuch land to a good condition, it ſhould be well manured and fallowed.

Cole-ſeed extracts ſuch a quantity of ſalts from the earth, that the Flemiſh farmers tranſplant it, as well to divide betwixt two pieces of land the loſſes in point of quality it occaſions to the ſoil, as to procure better crops. For both theſe reaſons, they alſo ſometimes tranſplant their cole-ſeed on land newly broke up.

In the country of Amiens they tranſplant their cole-ſeed after the plough in cloſe furrows: this method is better than that above-mentioned; but it is greatly inferior to the Flemiſh method; for the rows are diſordered, and the plants cruſhed by the horſes feet; and having, beſides, no freſh earth laid on them, they cannot grow to ſuch fine plants; and, on the other hand, the earth, which is not kept ſtirring, cannot receive any conſiderable benefit from the influences of the air.

The marquis obſerves, that, there is, however, a caſe in which this method muſt be reſorted to; which is, when the plants are grown ſo tall, and have ſuch long roots, that proper holes cannot well be made for them with a dibble, they ſhould be laid in the furrows after the plough, and open furrows, or trenches, ſhould be left at the diſtances already mentioned; but the earth from theſe trenches is with greater difficulty thrown on the beds, becauſe the cole-ſeed, in this method, is planted lengthwiſe, whereas, in the other method of tranſplanting, the plants croſs the beds.

In this eſſay the marquis de Turbilli relates a very curious fact, which we ſhall inſert in his own words:

"In the year 1755, I ſaw in the neighbourhood of Guiſe, in France, ſome cole-ſeed tranſplanted into a field, containing about eighteen acres, which had always borne fine corn, but had no great depth of ſoil.

"At the depth of ſeven or eight inches from the ſurface lay a bed of red clay, which the farmers are ſo much afraid of mixing with their good earth. This land was firſt well dunged, and when the cole-ſeed was tranſplanted, the red earth out of the trenches was thrown on the beds.

"All the inhabitants of the country flocked to ſee this work executed, which was under the direction of a Flemiſh farmer. They pretended that he ſpoiled the land, and that no corn would grow on it afterwards.

"However, during the courſe of the winter, the red clay became mellow; the rains which waſhed the dung, ran into the trenches, carrying with it a ſediment, and a portion of ſalts, improving the earth that was in the enſuing ſpring to be thrown on the beds amongſt the rows of cole-ſeed, which came on amazingly.

"At the harveſting of the next crop, the inhabitants did not fail of coming to ſee what ſort of corn ſucceeded the cole-ſeed; and being perfectly well convinced that it was much finer than the land was accuſtomed to bear, they laid aſide their prejudices, and adopted the planting

of

of cole-ſeed. In the year 1761, there was in that ſingle quarter above one hundred acres of tranſplanted cole-ſeed."

Muſt we not, on ſuch good authority, allow that the notion of the under-turf earth being poiſonous is ideal? If indiſcreetly laid over the ſurface of the land when it either is, or is to be ſown, under certain crops, it may be prejudicial, and ſo may the beſt practices in huſbandry, if injudiciouſly followed.

A correſpondent of the editors of the Muſeum Ruſticum has given us the following method of cultivating cole-ſeed in Eſſex. He begins with obſerving, that the great conſumption of rape-oil in that country in manufactures, together with the natural richneſs of their land, induces them often to ſow the cole-ſeed or rape-ſeed, which thrives there extremely well.

"In moiſt ſoils, continues he, we ſow it on four-bout lands, the large furrows between the ridges ſerving to drain off the water.

"We do not truſt to the richneſs of our land alone, for we almoſt always lay on a conſiderable quantity of manure; being of opinion that land cannot be in too good heart for this plant, which requires a great deal of nouriſhment, having a very luxuriant growth, and draining the land much: for this reaſon, it is in vain to attempt ſowing it on poor, hungry, dry ſoils, on which it will never thrive, nor turn to profit.

"Land cannot be too mellow, nor too much pulverized, for the cole-ſeed plant; for it not only requires a rich ſoil, but alſo the land muſt be in excellent tilth: we allow land, on which it is to be ſown, ſometimes three or four ploughings, according to the nature of the ſoil: if ſtiff it requires more tillage; if a looſe, rich, crumbly loom, leſs ploughing will do.

"In July we harrow the field over, and afterwards ſow on it half a peck of ſeed to the acre broad-caſt. As ſoon as the plant gets out of its ſeed-leaf, I hoe it as I do my turnips, thinking this a better way than to let it grow rambling without after culture, as ſome of my neighbours do.

"This crop is, without care, very apt to be deſtroyed by ſlugs, whilſt the leaf is young and tender; but to prevent this, I always ſtrew over the young plants a mixture of ſlaked lime and wood-aſhes: about ten buſhels of ſlaked lime, and fifteen of the aſhes, will be quite ſufficient for an acre: this is the quantity I uſe.

"I find great beneſit from this practice, as it not only burns up the ſlug, and deſtroys many pernicious inſects, but alſo greatly helps to forward the crop, inſomuch that it gets to a ſtrong head before winter, and yields me a plenty of fodder for my cows, ſheep, &c.

"A part of my ground will ſometimes unaccountably fail; that is, the ſeeds will not come up; but as the cole-ſeed plant bears tranſplanting extremely well, I make my men remove ſome of the plants, where they ſtand too thick, to ſupply the deficiencies: theſe are ſure to take, eſpecially if rain enſues: if it does not, I cauſe them to be watered, which is ſoon done, as they ſeldom fail in great quantities.

"The cole-ſeed plant is ſo hardy, that it bears without injury, the froſts of our ſevereſt winters; but the north-eaſterly winds, if very cold and piercing, will ſometimes greatly injure a crop, and there is no guarding againſt theſe.

"We ſometimes in this county ſow cole-ſeed merely for the ſake of the winter feed it affords our cattle; in which caſe we plough it up early in the ſpring, and are almoſt ſure of a good crop of ſound barley. This is not generally practiſed, becauſe it requires great care to clear the land of the cole-ſeed plant, which would otherwiſe grow up with the barley, and injure it; I, however, and ſome others, have often practiſed it to advantage.

"One thing I muſt obſerve before I conclude, which is, that cattle muſt be fed with this plant with great care, or it will have fatal effects: it is beſt to give them with it, at times, ſweet dry hay: this corrects the ſuper-abundant moiſture of the plants, and ſerves to dry up the uncorrected and raw juices that would otherwiſe mix with the maſs of blood in the cattle: ſuckling ewes may feed on it heartily, however with very little danger: and, in fact, experience will ſoon direct the young farmer in the management of his cattle in this reſpect.

"We reap, for the moſt part, our crops of cole-ſeed; and as it is very apt to ſhed, we prepare frames lined with threſhing cloths, each drawn by one horſe, to receive the heads of the plants as faſt as they are cut off.

"When this crop is properly managed, nothing pays better." *Muſem Ruſticum, vol.* I. *page* 237.

Another correſpondent of the editors of the above work, gives us the following method of cultivating cole-ſeed in the fen countries.

He obſerves, that they make uſe of no muck or compoſt, but have recourſe to the method of burn-baking, which we have already deſcribed under that article. *See* BURN-BAKING.

As ſoon as the land is burnt, and the aſhes ſpread, it is immediately ploughed, and the ſeed is ſown as ſoon as poſſible.

"The quantity we ſow, continues he, on an acre is about half a peck, or rather leſs: it would be proper to draw a light hurdle, ſtuck with thorn ſpray, over it, by way of prevention againſt the fowls. We plough the land about ten paces wide, that the furrows may carry the water off, where the land lies on a little deſcent.

"There is one thing to be obſerved in the ploughing, if the ſquare of the piece will admit of it: you ſhould plough for burning from eaſt to weſt, and when you plough for ſowing, then plough north and ſouth, for theſe reaſons: firſt, the land will break better for being croſs-ploughed; and then the land, when ſown, will lie as it were full face to the ſun; but this cannot always be done.

"As ſoon as the cole-ſeed, begins to ſprout, it is often all deſtroyed with what we call a black fly; an inſect ſo ſmall, and being black, the ſame colour of the land, that it is almoſt impoſſible to ſee it, otherwiſe than as you walk among the ſeed, if you look ſteadily, you will perceive ſomething hop or fly off, like the hopping of a flea: I have often endeavoured to diſcover what ſort of fly this is, but never could find one, though they will find the ſeed immediately on its firſt ſprouting.

"It has many more enemies as it advances in its growth; the next is what we call the black canker; it is a ſmall black worm, about a quarter of an inch long, or rather more: this takes poſſeſſion when it is about the ſize of a ſmall cabbage-plant, but windy and rainy weather are great helps to the deſtroying that inſect.

" There is yet another enemy, but he appears in a different dreſs: this is the green catterpillar, more than an inch long, but does not appear till about the latter end of September, and very often deſtroys a great deal of it; but the froſty mornings generally diſpatch him.

" I have now gone through the various ſteps of the culture of cole-ſeed to this particular period, with a ſuppoſition, that we have eſcaped all thoſe dangers. I will now give you a ſhort ſketch how we proceed when we are attacked with thoſe enemies above-mentioned.

" If the ſmall fly eat the firſt ſprout, it is uſual to ſow the land again; but I would adviſe the farmer, before he ſows, to harrow the land with a light harrow with wooden teeth; for if the harrow be heavy, it will tear up the furrows: my deſign in this is to raiſe a freſh mould, by which means the ſeed will ſtrike much ſooner than if nothing was done to it.

" As to the black canker, the only method I can adviſe is, to let two men take a waggon-rope, each take one end, and draw it over the plant about twice in a place, by which means the canker will be beaten off the plant on to the ground, which ſeldom riſes again.

" As to the green caterpillar, the ſame expedient, I believe, would be of ſervice to that; but, as I have ſaid before, we are chiefly relieved from it by froſty mornings."

The writer then proceeds to give his readers an account of the uſes the cole-ſeed is put to in the fen countries, when the plant is arrived to its utmoſt perfection.

" We eat off, ſays he, with ſheep that are about half or three parts fat, to make them fit for the butcher; for cole-ſeed is the moſt fattening food for ſheep that is known in this part of the world, greatly exceeding turnips, as a ſheep will thrive more at cole-ſeed in one month than it will at turnips in two.

" The uſual time of putting them into the ſeed is about Michaelmas: however that depends upon the farmer's own conveniency; but if the ſheep are poorer than as above deſcribed, they muſt be put in ſooner. We generally manage ſo as to have the ſeed eaten off by about Old Candlemas, for this reaſon; if the land be ſtout and good, there is a chance for the ſeed to ſtand for a crop.

" If the farmer finds the ſeed good enough to ſtand for a crop, I would adviſe him, if the ſtumps or ſtalks be left high, as where the cole-ſeed is ſtrong and good is moſtly three or four inches off the ground; otherwiſe he will find his crop will receive great damage by the ſtumps being left very ſhagged and torn, which lets in the wet, and rots abundance of them; and even thoſe that do grow have not the vigour as thoſe have that are mowed; for the former is, as it were, ſpread to the ſnow and rain, while the latter is wholly ſecured from them both, and will ſupport the ſprouts, that ſhoot out at the ſides, with ſtrength and vigour.

" Cole-ſeed is a plant that will ſhed or ſhale its ſeed very greatly, if it is not reaped in proper time; from which great loſſes have been known, where the farmer has thoughtleſsly let it ſtand too long before he begins to reap.

" If the ſeaſon has been kind, that the crop comes on all together, though we often ſee the contrary, the farmer is, in either of theſe caſes, as ſoon as he perceives any part of it turn browniſh, to begin to cut, notwithſtanding the generality of the ſeed will be green; but if you let the whole ſtand till the laſt becomes brown, like the firſt, the firſt part will be entirely loſt.

" But it will perhaps be ſaid, ſhould not the latter part be as ripe as the firſt? My reply is, as cole-ſeed is a ſmall ſeed, and the ſtalks on which it grows are very large, the ſtalk will feed that part that is green, after it is reaped, ſo as that of the latter will be nearly equal to the firſt; by which means both are ſaved.

" There is a particular method of laying it on the ground, when reaped, different from all other crops; for inſtance, ſuppoſe the people reaping a field from north to ſouth, every two men ſhould lay in his reaps, with the heads of the ſeed to each other, but not to touch, the heads and the ends of the ſtalk lying eaſt and weſt. We ſhall now proceed to the threſhing.

" The diſtance of time between reaping and threſhing depends ſo entirely upon the weather, that it is impoſſible to give particular directions in that matter, otherwiſe than that when the ſeed has lain till the ſtalk or ſtraw is dead, and turned white, and the ſeed, ſome of it being rubbed out of the coſh, or pod, appears black and plump, and does readily come out, then is the time to begin to threſh.

" Though the bottom of the reaps will be a little greeniſh, they muſt be not turned to weather the under ſide; if you do, it will bruſh out a great deal of the top ſide: and if the weather ſhould prove wet in the time it is threſhing, even in that caſe it muſt be turned, but raiſed up gently and laid lightly on the ſtubs; in that ſituation it will dry a pace.

" It is always threſhed in the field, upon a cloth, about twenty yards long, and eighteen yards wide. To deſcribe each perſon's employment, I think, it is not to be done, ſo that a perſon that never ſaw it can have an idea of it; but as it is, I think, if every perſon concerned in a cole-ſeed ſale, for that is the name we give the cloth and people when at work, be clever in their places, a curious piece of mechaniſm, if I may be allowed this expreſſion, where men and women are made uſe of inſtead of wheels and pullies.

" The number of people employed at a cole-ſeed ſale are, generally, about twenty: ſeven gatherers; theſe are women, great boys and girls: I have ſaid ſeven; but where the crop is thin it requires more, ſometimes eight or ten, or more: but where the crop is thick, a leſs number may do; theſe people gather the reaps up with a ſickle, for, as their arms cannot reach round the reaps, they would ſqueeze it together, and bruſh a deal of ſeed out, if they had no ſickle: they put it into a ſheet called a bearing-ſheet, of which there are two belonging to every ſale; it is about ten feet long, and about ſeven feet wide, and has loops on each ſide, through which a light pole is put, and is carried, when filled, by two men to the cloth: theſe are called the bearers.

" When the ſeed is lain on the cloth, there is a man called the layer-on: he with a ſickle lays it on a row, acroſs the cloth, for the threſhers, which are four, two on each ſide the row of ſeed. While the threſhers are threſhing the firſt row, or floor, the layer-on lays on another row at a proper diſtance from the other: when they have threſhed the ſecond once over, they turn to the firſt, and threſh it all a ſecond time: they have then done their parts: there are two men called ſhakers off, that immediately follow the threſhers: the firſt of them throws the cole-ſeed ſtraw up; the other ſtrikes it as it riſes, which helps to knock out what ſeed may be left: theſe two men, with wooden forks for that purpoſe,

poſe, convey the ſtraw off the cloth, over the bolſter, to a perſon that takes it away; he is called the ſack-ſtraw.

" After the ſhakers off, come two perſons, one of them a woman: they take off the coſhes or pods, and ſhort broken ſtraws, with rakes made for that purpoſe: theſe are called the before and behind cavers. The behind caver muſt be a perſon of ſtrength and activity, in order to do his work as it ought to be done; for upon him the ſaving or throwing away of a good deal of the ſeed depends; ſo that he ſhould be a nimble briſk fellow, and careful too, or he is by no means fit for that place.

" If there be a good crop, and the plants yield well, the weather bright, and the ſeed threſh eaſy, thirty combs, or one hundred and twenty buſhels, may be threſhed in the day; but ſometimes not more than ten or twelve combs.

" Early the next morning the four threſhers throw the ſeed upon the cloth, when the farmer comes with ſacks and a waggon, and takes it away, ſo that the cloth is cleared and ready againſt the people come to work." *Muſeum Ruſticum*, *vol.* I. *p.* 418, and *vol.* II. *p.* 79.

If this plant be ſown for the food of cattle, they will be large enough for feeding by the middle of November, when, if there be a ſcarcity of other fodder, this may be eat; but if there be not an immediate want of food, it had better be kept as a reſerve for hard weather, or ſpring ſeed, when there may be a ſcarcity of other green food. If the heads of theſe plants are cut off, they will ſhoot again early in the ſpring, and produce a good ſecond crop in April, which may be either uſed for cattle, or ſuffered to run to ſeed. It is ſo hardy as not to be deſtroyed by froſt, and therefore of great uſe in hard ſevere winters, for feeding of ewes: for when the ground is ſo hard frozen that turnips cannot be taken up, theſe plants may be eat for a conſtant ſupply. Mr. Miller ſays, he has found, in ſeveral places where he has ſowed this ſeed, that one acre of land planted with cole will produce nearly as much food as two acres of turnips; that this will afford late food after the turnips are run to ſeed; and that, if the plants are permitted to ſtand for ſeed, one acre will produce as much as, at a moderate computation, will ſell for five pounds; clear of charges.

Partridges, pheaſants, turkeys, and moſt other fowls, are ſo fond of theſe plants, that, if there be any of them in the neighbourhood of the field where they are cultivated, they will flock thither, and lie conſtantly among them.

The cakes of cole-ſeed, which remains after the oil is extracted, are exceeding good food for cattle, and will very ſoon fatten them. They are indeed apt to render the fat of ſuch beaſts yellow and rank; but this may be eaſily removed by feeding them with dry fodder a fortnight or three weeks before they are killed.

COLE-*Cale*, or *Keal*, ſignifies pottage in the northern parts of England and Scotland.

COLEWORT, or *Dorſetſhire Kale*, is a ſpecies of cabbage, formerly much cultivated in gardens, but at preſent little known, cabbage plants being ſubſtituted in its room. It is however a very uſeful plant for feeding milch-cattle in the ſpring, when there is a ſcarcity of herbage; for it is ſo hardy that no froſt will kill it.

The beſt method of cultivating this plant in the fields is, to ſow the ſeeds about the beginning of July, chooſing a moiſt ſeaſon, which will bring up the plants in about ten or fourteen days: the quantity of ſeed for an acre of land is nine pounds. When the plants have got five or ſix leaves, they ſhould be hoed in the ſame manner as turnips, cutting down all the weeds from among the plants, and alſo thinning the plants where they are too thick; but they ſhould be kept thicker than turnips, becauſe they are in more danger of being deſtroyed by the fly: this work ſhould be performed in dry weather, that the weeds may be killed. About ſix weeks after the plants ſhould have a ſecond hoeing, which, if carefully performed in dry weather, will entirely deſtroy the weeds, and make the ground clean, ſo that they will require no farther culture. In the ſpring they may either be drawn up, and carried out to feed the cattle, or the beaſts may be turned into the field to feed upon them as they ſtand; but the former method ſhould be preferred, becauſe there will then be little waſte; whereas, when the cattle are turned in among the plants, they will tread down and deſtroy more than they eat, eſpecially if they are not fenced off by hurdles. *Millar's Gard. Dict.*

COLLAR, the part of the harneſs that goes round a horſe's neck.

COLLAR *of brawn*, is the quantity of brawn bound up in one parcel.

COLLATERAL *Bee-Boxes*. *See the article* BEE.

COLLEY *Sheep*, ſuch ſheep as have black faces and legs. The wool of theſe ſheep is very harſh, with heirs, and not ſo white as that of other ſheep.

COLLIFLOWER. *See the article* CAULIFLOWER.

COLONY, a number of people drawn from the mother country, to inhabit a diſtant place. And hence the ingenious Mr. White has applied the word to a ſtock of bees. *See* BEE.

COLT, a foal, or young horſe.

Foals are ſeparated from their dams after five, ſix, or at fartheſt ſeven months; experience having ſhewn, that ſuch as are ſuffered to ſuck ten or eleven months, though uſually larger and fuller of fleſh, are not equal, in other reſpects, to thoſe that are taken away ſooner. After living ſix or ſeven months on milk, they are habituated to a more ſolid nouriſhment, having bran given them twice a day, with a ſmall quantity of hay, which is increaſed as they advance in age, and in this manner they are kept in the ſtable, as long as they expreſs any deſire of returning to their dams: but when this uneaſineſs is over, they are turned into the fields, taking care never to do it faſting. An hour before they are turned to graſs, a feed of bran, and ſome water ſhould be given them; nor ſhould they be expoſed to either ſevere cold or rain: in this manner the firſt winter muſt be paſſed. In May following, they muſt not only be turned into the fields every day, but may lie in the open air till the end of October, taking care not to let them feed on the after-math; for by accuſtoming themſelves to this remarkably delicate and ſucculent graſs, they would contract a diſlike to hay, which, together with bran mixed with barley and oats ground, ſhould be their principal food during the ſecond winter. In this manner they are to be kept till their fourth year, ſpending the days only in the paſtures, during the winter; but both day and night in the ſummer. When they reach that age, they are to be taken from the paſtures, and fed with dry meat; but in this

change of food ſome precautions are requiſite; as during the firſt week to feed them only with ſtraw, and give them proper medicines againſt worms, which often trouble them from bad digeſtions and too rank graſs.

At weaning young colts, they ſhould be kept in a clean ſtable, not over warm, which would render them tender, and too ſenſible of the impreſſions of the air. They muſt frequently have freſh litter, and be rubbed often with ſtraw; but not tied or curried till they are three, or at leaſt two years and a half old; for the roughneſs of this friction would give them pain, and their ſkin being too tender to endure it, inſtead of thriving, they would fall away. The rack and manger ſhould not be too high, leſt the neceſſity of liſting up their heads to reach their food, ſhould occaſion them to carry their heads in that manner, which would ſpoil their cheſts. When they are a year, or a year and a half old, the hair on their tails ſhould be cut, as the ſucceeding growth will be ſtronger and thicker than the former. When they are two years old, they ſhould be ſeparated, and the ſtone colts kept with the horſes, and fillies with the mares, otherwiſe the former would fruitleſsly weaken themſelves with the latter. At the age of three years, or three and a half, they ſhould be broke, and rendered docile. In order to this, a light eaſy ſaddle ſhould be put on their backs, and continue there three or four hours every day. They ſhould alſo be uſed to receive the bit of a ſmall bridle into their mouths, and ſuffer their feet to be taken up, and ſome ſtrokes given on the ſole, as if ſhoeing them. If they are deſigned for draught horſes, a harneſs ſhould be put on their bodies, and afterwards a ſnaffle bridle ſhould be added. They ſhould then be trotted on level ground, but without a rider, the perſon only holding the reins, and either the ſaddle or harneſs on their backs: and when the ſaddle-horſe eaſily turns, and freely comes up to him that holds the rein, he ſhould mount on his back, and diſmount again immediatly, without riding him, till he is four years old, as before that time the weight would be too much for him: but at four years old he may be ridden, and trotted at ſmall intervals. *Buffon's Hiſtoire Naturelle, tom* IV.

COLT-EVIL, a diſtemper to which young horſes are ſubject, conſiſting of a ſwelling in the ſheath, occaſioned by their having full liberty with the mares before they are able to cover them.

This diſeaſe may be eaſily removed at the beginning, by the uſe of warm fomentations, made of emollient herbs, &c. but if the ſwelling be hard and inflamed, bleeding and purging are both neceſſary; and it may alſo be proper to tie his yard up to his belly, making a hole for his water to paſs free. *Gibſon's Farriery, vol.* II. *page* 168.

COLTS-FOOT, *fole-foot, horſe-hoof*, or *bull-foot*, the name of a very common weed, whoſe ſcaly ſtalks ariſe in February, bearing one yellow compound flower, which is ſucceeded by a hairy white down. The leaves come out later. They are ſhaped ſomewhat like a horſe's hoof, and are downy underneath.

This weed, which delights to grow by the ſide of rivers, increaſes ſo faſt by its ſeeds and rambling roots, every piece of which laſt will produce a new plant, though they have been broken by the plough, that it cannot be extirpated without much difficulty, and a conſiderable time. Carefully pulling up the roots every time the earth is ſtirred, or the leaſt veſtige of the plant appears, and preventing its running to ſeed, are the moſt effectual means of deſtroying it in arable land; and this is beſt accompliſhed by the horſe-hoeing huſbandry: but totally to extirpate it, the ground muſt be laid down long to graſs. One of Mr. Liſle's neighbours almoſt deſtroyed it by two ſucceſſive crops of vetches; and he himſelf is clearly of opinion, that it may be killed by letting the land lie a ſufficient time under clover, or rye graſs; becauſe, ſays he, the roots of the natural graſs matting more and more every year, will, in five or ſix years, ſo bind the ſurface of the ground, that the colts-foot will not be able to pierce through it, and will therefore die for want of air. He ploughed up broad clover in the beginning of July, and turned up the roots of colts-foot, in which he obſerved, between earth and air, many little buds, ſhot forth, of the bigneſs of the mid-ſummer buds in fruit-trees, probably to be the leaves or flowers of the next year; and at the depth of five, ſix, and even ſeven inches, he remarked here and there a ſhoot, of a callous body, like the root itſelf, from one to four inches long; perhaps deſtined to be future roots: he experienced that a winter's fallow will not deſtroy theſe roots, and that they cannot reſiſt the effect of ſummer fallows, in which they are turned up, and expoſed dry to the ſun. It is therefore neceſſary to pick them as clean as poſſible, and burn them: for it is not to be ſuppoſed, that all the roots which are turned up in a ſummer fallow will wither of themſelves: on the contrary, ſuch of the buds at the joints of theſe as are buried under ground, will ſhoot out again if much rain falls, or the ſeaſon be wet.

COMB, a meaſure of corn, conſiſting of four Wincheſter buſhels; but in the fen country the comb generally conſiſts of four buſhels, and each buſhel of eight gallons and a quart.

COMMON, an open piece of ground uſed equally by many perſons.

The marquis of Turbilli has treated the ſubject of breaking up commons and waſte grounds in ſo maſterly a manner, that it will be neceſſary to give the ſubſtance of what he has advanced on this intereſting ſubject, nearly in his own words.

"Upon the death of my father, ſays the marquis, which happened in the year 1737, I inherited the lands of Anjou, of which I am now going to ſpeak. They lie contiguous, and form a pretty conſiderable extent.

"Hills and vales render the country uneven in many places; though, in others, there are ſpacious plains, with ſeveral brooks, and a ſmall river. The ſoil is of three kinds, bad, middling, and good: but this laſt is leaſt frequent. Moſt of the lands, being of a middling quality, are fertilized only by dint of care and manure: wheat grows on one ſpot, meſlin on another, rye on a third; and ſometimes it is neceſſary to ſow theſe three different ſorts of grain in the ſame field; ſo much does the ſoil vary: but, in general, we ſow more ground with rye, than with any other corn. Buck-wheat, barley, oats, hemp, flax, and other equally uſeful productions are likewiſe cultivated in theſe parts. The vine proſpers here very well, eſpecially on the ſunny ſide of banks and higher grounds: our wine, both red and white, is good; our fruit trees thrive well; and ſo does the white mulberry, of which I made large plantations ſome years ago. The oak, the elm, the beech, and other foreſt trees, grow extremely well in theſe lands. Such is the

ſoil

ſoil of this diſtrict: the climate is mild and temperate, as is the reſt of Anjou.

"Three ſides of this eſtate border upon immenſe tracts of uncultivated heaths, which ſpread through the greateſt part of the province, and belong, ſome of them to the king, and others to different lords, eccleſiaſtical and temporal. However, the ſituation of my houſe, and of the chief village, is advantageous, being nearly in the centre of the whole, and within about ſix miles of three pretty towns.

"Such was my eſtate when I took poſſeſſion of it: not a quarter part of the land was cultivated, and even that very badly: the reſt was either abandoned by the huſbandmen, or had not been cultivated at all. Moſt of the meadows along the brooks and rivulets were become marſhes, productive of ſcarce any thing but ruſhes. The vineyards were ruined, and the woods deſtroyed. A third part of the farms belonging to the principal pariſh where my ſeat is, were un-tenanted, for want of farmers to rent them. The inhabitants of this place were very poor, and did not, in general, raiſe corn enough of any kind to ſubſiſt them half the year: nay, ſuch was their indolence, that they choſe rather to ſtroll about and beg during the other half, than be at the pains of beſtowing proper culture upon their land, which, with that culture, would have maintained them decently.

"This deplorable condition of my eſtate, which I have here repreſented fairly, without exaggerating any one particular, determined me, early in life, to read attentively all the moſt approved writers upon agriculture, and to obſerve carefully every improvement I met with in my travels. Even the campaigns in which I ſerved did not interrupt theſe inquiries; for agriculture and arms never were by any means incompatible. Under theſe circumſtances, I reſolved to execute upon my own property, deſigns which my knowledge of the place, concern for the unhappy ſituation of its inhabitants, and regret to ſee what ſmall returns were made by ſo large an extent of ground, naturally ſuggeſted.

"I plainly foreſaw that this undertaking muſt be a work of time; neither my fortune, nor the number of hands I could procure in the country, allowing me to go beyond the clearing and improving of a certain ſpace every year. Some gentlemen of knowledge, judgment, and public ſpirit, to whom I communicated my thoughts, approved of them, commended my deſign, and exhorted me ſtrongly to carry it into execution; repreſenting, beſides the advantages which would neceſſarily accrue to me, the general benefit which ſuch an example might be of to my country, filled as it is, with numerous tracts of uncultivated land. This laſt reflection animated me more and more.

My firſt care was, to endeavour to extirpate the ſpirit of indolence, and conſequent love of begging, which prevailed among my peaſants in general. To this end, I gave public notice of my intended improvements, with a declaration, that I would conſtantly employ every man, woman, or child above eight years of age, who might not have buſineſs of their own to do, on condition of their leaving off begging. At the ſame time I ordered an account to be taken of ſuch as were not able to work. Theſe I afterwards examined more particularly myſelf, and found among them ſeveral who, though they were not fit for hard labour, were capable of doing many uſeful things, in which I accordingly employed them. By this means, my liſt of really helpleſs people was reduced to a ſmall number, which I provided for, till their relations ſhould be able to keep them by means of what they earned from me. A few, and only a few, of theſe poor objects, who either had no relations, or ſuch as in truth could not help them, became a dead charge: though this ſoon leſſened, and is now inconſiderable.

"An innumerable multitude of rabbits infeſted my land. Againſt theſe I declared open war; being determined abſolutely to deſtroy them. This has already been ſeveral years a-doing, and is not yet entirely completed. Some of them ſtill remain, ſheltered in their burrows at the foot of riſing grounds, and others make incurſions from the neighbouring woods and warrens. However, they do me no great miſchief now; and even then I drove them from the place where I wanted to work.

"In the month of June 1737, I begun my improvements with clearing ſome of the land near my houſe. This ground was ſo poor that no farmer would even attempt to make any thing of it, ſerved only to feed a few ſtinted cows, and was over-run with briars, thiſtles, and broom, which, being cut up, and laid in heaps, from ſpace to ſpace, were burnt upon the ſpot, and yielded a conſiderable quantity of aſhes. Theſe were then ſpread, and immediately turned in by a ſingle plowing, leſt their virtue ſhould exhale. During the ſummer, this land was ploughed ſeveral times, different ways, in order to looſen it, and endeavour to deſtroy the weeds. I had bought for this purpoſe oxen, which are generally uſed for ploughing in Anjou; but my horſes helped them, eſpecially for harrowing. Here my poor peaſants, men, women, and children, were employed to break the clods and pick off the ſtones; and as I had more dung than my arable lands required, I ordered about half the quantity that is generally uſed in other places, to be laid upon this ground, which was afterwards ſowed at the uſual time. This firſt trial ſucceeded, and the crop was very good; though moſt of my neighbours were of opinion that all my labour would be loſt.

"In 1738, I undertook another piece of ground, adjoining to the former, and of the ſame kind. I began in March, proceeded as before, dunged it, and had equal ſucceſs. The ſecond crop of the former ſpot was ſtill more plentiful. This ſummer I gave a thorough fallow to ten acres which had long been under corn, and ſowed part of them with hemp and flax, for a purpoſe which will be mentioned hereafter. I likewiſe recruited my vineyard, and drained my meadows. Numbers of day-labourers were employed in cleanſing the rivulets and brooks which run thrugh them. In the winter of this year an accident happened, which had like to have overſet my whole undertaking. The oxen which I uſed for ploughing, and which were grown lean, it was ſuppoſed through labour and fatigue, were on a ſudden covered with vermin, which eat into their fleſh: ſeveral remedies were applied, but in vain, the vermin re-appearing in a few days. We knew not to what cauſe to aſcribe this diſorder, which was deſtroying animals without whoſe aſſiſtance I could not proceed: beſides which, the loſs would, in itſelf, have been conſiderable. They had hitherto been fed with hay only; though the cuſtom of the country was to mix it with an equal quantity of wheat-ſtraw. As I had not yet a ſufficiency of this laſt, I bought ſome, gave it to them mixed with hay, and allowed them oats from time to time when they had been

hard-

hard worked. This mended them a little: but they did not recover entirely, or get rid of their vermin, till they fed on green graſs, and lay out of doors.

"I begun this year to make new roads and cauſeys a-croſs my meadows, marſhes, and riſing grounds, for the eaſier conveyance to and from my fields; the old ways being often impaſſable in many places. This has been a very long and expenſive work; nor is it yet quite finiſhed. I alſo bought at this time a number of ſheep, which have ſince increaſed conſiderably: for, notwithſtanding the great extent of this uncultivated land, where many of them might eaſily have been fed, none were ever kept upon it before. The people of the country thought they could not thrive there, on account of the marſhes, and of a plant called white root, very prejudicial to them, found in ſeveral parts of the lay-grounds and commons. Moſt of theſe weeds was pulled up at a ſmall expence; and the ſheep, who are fond of this herb, eat up the reſt, which was ſo little that it could not do them much hurt, though ſome of them were ſick with it. The conſtant feeding of the ſheep, and their dung, afterwards completed the deſtruction of this noxious plant, and brought up good graſs in its ſtead. This ſhews how farmers may often get rid of any ſuch bad weed.

"In 1739 I took the next contiguous land, going round my manſion: a method which I have always followed; ſo that my improvements have been, from year to year, more and more diſtant from my place of reſidence. The ſoil I now fell upon was tough, ſtrong, and only thin graſs grew upon it, with here and there a few brambles and other wild productions, which were ſoon cut up. This ground was broken up only with the plough: ſome dung was laid upon it, and I ſowed it directly with winter oats, which ſucceeded very well. My improvements of the two laſt years yielded plentiful crops, not only of corn, but alſo of hemp and flax. Theſe laſt were dreſſed, and given to the women and girls to ſpin; paying them different prices, according to the fineneſs of the thread. They applied themſelves to their work, and by degrees became perfect in it. By this means I accompliſhed my deſign of finding employment for theſe women and girls all the year round, and afforded them the means of procuring an honeſt livelihood, as well as to thoſe whom age or infirmities rendered incapable of working abroad.

"The buſineſs of the field was always preferred in the ſeaſons proper for it, and when the weather permitted; keeping in my eye Cato's advice, never to work within doors, while there is any thing to be done without, nor to do that in fair weather, which may be done in wet. I have continued this ſpinning ever ſince; and have allotted for the growth of hemp and flax particular ſpots, which I have incloſed with hedges and ditches, and kept in good heart and with fine tilth. They have yielded plentiful annual crops without being reſted; only dunging them every other year; for hemp does not impoveriſh the ground when it is properly cultivated. My vines, meadows, and ways were not neglected.

"In the beginning of this winter I gave my oxen hay mixed with an equal quantity of rye-ſtraw, not having wheat-ſtraw enough to anſwer that purpoſe. This ſucceeded to my wiſh. My oxen continued in perfect health, free from the vermin I mentioned before, and in better plight than thoſe in the neighbourhood, which were fed with hay and wheat-ſtraw. I have continued to give them this food as long as they lie within doors, and find it anſwer extremely well. During this time they have no corn, even though they work; and I do not find that this ſuppreſſing of their otherwiſe uſual allowance of oats, renders them at all leſs hearty and vigorous. This quality of the rye-ſtraw may be of great advantage in countries where oxen are uſed for ploughing.

"In the year 1740, I was obliged to make a conſiderable addition to my number of ſervants, and ſtock of cattle of all ſorts, in proportion to the increaſed extent of my improvements. It may perhaps be thought, that ſo many ſervants would eat me out of houſe and home. This I had guarded againſt from the beginning. All thoſe employed in my huſbandry lived by themſelves, in ſome of the out-houſes, where they had their own kitchen, and a certain ſtated allowance, ſuited to their uſual manner of life; ſo that they had no ſort of connection with the others, whoſe more immediate buſineſs it was to attend me.

"The land which I improved this year was covered with heath, broom, and furze, which had grown very thick and high. In the ſpring, when the weather was dry, I ſet fire to this ſurface, after taking due precautions to hinder the flames from ſpreading too far. The whole burnt very well, and I was in hopes of being able to plough up this ground without paring off the turf, as I had done with my other land the year before. This would have been a conſiderable ſaving; eſpecially as the aſhes were ready ſpread. But I ſhould have conſidered that different lands require different treatment. Ploughs, ſtronger than uſual, were made on purpoſe for this work; but the roots of the furze and broom, which had reſiſted the fire, broke them; and though I doubled the number of my cattle for draught, ſeveral of the oxen were ruined by this hard work, in which I perſiſted with too much obſtinacy. In vain did I plough it over and over, and break every clod both before and after ſowing it; the broom and furze were not deſtroyed, but made new ſhoots every where: the land continued unkindly and ſour, and the oats which I ſowed in it yielded ſcarce any crop; in ſhort, repeated ploughings and dunging were neceſſary during three years, before it could be brought to a good tilth, or thoſe noxious plants be quite extirpated. I came badly off in this experiment: but my former improvements, which I had continued to manure and ſow, luckily produced an abundant crop: that of the laſt year yielded a good quantity of wheat, which kept up my eſtabliſhment, though it did not compenſate for the loſs I now ſuſtained. However, this diſappointment did not diſcourage me. It raiſed the laugh of the whole country at my expence; eſpecially of thoſe who had foretold from the beginning, that I ſhould not ſucceed. I gave them the hearing, and only reſolved not to fall a ſecond time into the ſame error.

"This year I eſtabliſhed a nurſery of fruit-trees, and alſo of foreſt trees from other countries. This nurſery, which ſucceeded very well, was of great advantage to me afterwards, to fill up the different plantations which I made as my improvements extended. I likewiſe repaired my woods, which had formerly been deſtroyed by cattle and deer. I ſurrounded them with ditches planted with hedges, in order to bring them into regular yearly cuttings; to which end I grubbed up ſuch trees as were

ſtinted

ſtinted in their growth, and filled every empty ſpace, either with young plants, or the ſeeds of others, according to the nature of the ground. By continuing to do this every year, my woods are now in excellent order, and afford regular cuttings, at the ſmall expence of keeping the fences in repair.

"In 1741, I had the ſame kind of land to deal with as the year before; but took care not to commit the ſame fault. Each day's cutting of the heath, broom, &c. was burnt, with proper precautions, as the workmen advanced, and the whole ſurface was dug by hand as it was cleared. By this means, the aſhes of theſe plants preſerved their fertilizing quality, and their roots were pulled up. Women and children ſhook the earth from off theſe roots, and turned them, whilſt they were drying in the hot weather. Theſe were alſo laid in heaps from ſpace to ſpace, and burnt upon the ſpot, where they yielded ſome aſhes, which were ſpread, and immediately buried with one turn of the plough.

"During the ſummer, this ground was ploughed ſeveral times; each time in a direction different from the former. My cattle were but little fatigued with this work; the heath, broom, &c. was almoſt entirely deſtroyed, and the ſourneſs of the land was in a great meaſure cured. I had then begun to make compoſts, which were mixed with the dung of the ſtall and ſtable, and proved of ſingular benefit. With their help, I was enabled to manure my newly broken up land ſufficiently; that is to ſay, to lay upon it half the quantity that is generally uſed of dung for the common run of lands. I ſowed this piece with rye, which yielded a plentiful crop. The crops from my former improvements, which I continued to ſow without reſting them, were likewiſe very good this year, excepting that of the laſt, which was alſo under rye, and yielded but a middling produce. My vineyards were now brought into as good order as any in the province; and I continued draining my meadows, and making roads and cauſeys.

"The war then calling me into Bohemia and Bavaria, I foreſaw that I ſhould be abſent ſome time, and conſequently not able to ſpend part of the year in the country, as I had uſed to do; to give directions to my people, and ſee my orders executed. Under theſe circumſtances, that my improvements might not ſtop, I gave the direction of the whole to an intelligent ſervant, who had lived with me a long while, and was married to an excellent houſewife: and, to intereſt him the more in the future ſucceſs of the undertaking, I agreed to allow him half of the profits of every kind; ſubjecting him to this only reſtriction, that he ſhould not impoveriſh the ground by too many crops. In this ſtate things went on till the end of the year 1748.

"In the mean time new pieces of land were broken up every year; but not ſo extenſive as the former; the expence of my campaigns not permitting me to lay out upon them ſo much money as before. I even ſtreightened myſelf, not to interrupt the progreſs of my improvements: which, in general, ſucceeded very well. I alſo revived an old method of breaking up land, by cutting off the ſurface with a paring mattock, and then burning it. *See the article* BURN-BAKING.

"During the whole of this time, I was but two years together without viſiting my eſtate, where my preſence was then very neceſſary. In all the other years, I gladly accepted the leave which was given me to ſee how my works went on; though I ſometimes did not ſtay above a fortnight among them. However, this was enough to give an eye to every thing that was doing; which is of great conſequence in undertakings of this kind.

"Peace being reſtored, I reſumed the perſonal guidance of my affairs in the beginning of the year 1749, and placed my old ſervant in a farm which I had to let, where his profits ſat him down at his eaſe. Though he was extremely faithful, and my improvements were carried on very well, yet I found that, for want of due care and attention at certain times, the crops were not equal to what they had been under my immediate direction: a circumſtance which plainly ſhews, that a work like this never thrives ſo well as in the hands of the owner himſelf.

"I now reſolved to purſue my improvements as before the war, that is to ſay, to break up larger tracts of ground every year, than had been done of late. Moſt of my yet uncultivated lands were, and had been from time immemorial, thick covered with high broom, heath, fern, &c. and experience had taught me that theſe were not to be broken up with the plough alone.

"Of all the methods which I tried, none ſeemed to me, as I ſaid before, ſo good as the paring-mattock and burning. I therefore fixed upon this, and, in conſequence, ſent for the workmen I had formerly employed in trials of this kind: but their number not ſufficing for the extent of ground which I purpoſed to break up this year, I ſent for others from a diſtance, and was weak enough to let theſe laſt perſuade me to contract with them at a ſet price, for paring the whole ſurface. I agreed to give them even more than they ought to have had for doing the work ever ſo well; for I was not yet thoroughly acquainted with the nature of this buſineſs. They began it in March; and, to earn their money the more eaſily, or rather to rob me, only ſkimmed off the mere ſurface, without hardly touching the roots of the plants, which they ſhould have cut up. When this work was done, as they called it, for the burning part did not belong to them, they immediately came to me, and aſked for their money, which I ſimply gave them, not ſuſpecting the cheat, but only thinking they had earned it very ſoon. When the turf of their cutting was dry, I ordered it to be laid in heaps, and burnt. The ſmall quantity of aſhes which it yielded, made me ſuſpect the roguery: but when I found that the roots in the earth broke ſome of my ploughs, in cutting only a ſingle furrow to cover the ſeed, and that there was no clearing it of clods, I was thoroughly convinced that I had been the dupe of theſe people, and that this paring would be of little ſervice. The wheat ſowed in this ground roſe indeed pretty well, and looked tolerably during part of the winter; but not being able afterwards to ſtrike through the cruſt formed by the remaining matted roots of the plants, moſt of it died, and the little that remained ſcarcely returned the ſeed: nor could this land be recovered till the next year, even by ploughing, breaking the clods, and dunging.

"The bad ſucceſs of this experiment, upon which a great deal of money had been thrown away, tried my patience, but did not diſcourage me. My neighbours began anew to exclaim againſt my projects, as they called them; and numbers of thoſe people who are determined at all events to oppoſe every novelty, be it right or wrong, were pleaſed to vent their ſarcaſms at

my

my expence. I let them talk on. The roguery of the people who had laſt pared my ground did not hinder me from ſtill thinking that this was the beſt way of breaking up new land, eſpecially heaths; and the event has ſhewed that I was right. This check, which was the laſt I received, made me reſolve to take my meaſures better for the future.

"The reſt of my improvement yielded very good crops this year, during which I continued to mend my roads and meadows. Theſe long winded works, for which only a certain ſpace of time, and a certain ſum of money, could be allotted every year, have been continued ever ſince, and indeed are not yet finiſhed. I likewiſe bought this year ſeveral hives of bees; though I had ſome before. Theſe uſeful creatures have multiplied exceedingly; eſpecially in a little garden, where my chief apiary is, ſituated between meadows and heaths, of the flowers of which they are remarkably fond. Though theſe induſtrious inſects thrive perfectly all over the country I am ſpeaking of, yet the inhabitants of theſe parts not only have not a tenth of the number they might keep, but ignorantly follow the old barbarous cuſtom of deſtroying the bees, when they want their honey, inſtead of only taking part. *See the article* BEE.

"I did not agree by the piece for breaking up the land I intended to improve in the year 1750, leſt I ſhould be again deceived; but hired proper labourers by the day. They began their work in March, and finiſhed it about the middle of June; cutting all the way deep enough to go under the cruſt, or net-work, formed by the roots beneath the ſurface; for I took particular care to ſee that this was done. When the turf thus pared, to the thickneſs of about four inches, was dried, piled up, and burnt in heaps from ſpace to ſpace upon this ground, it yielded a conſiderable quantity of aſhes, which enriched the ſoil for a long time. Wheat was then ſowed, and the plough eaſily turned up the furrow which covered the ſeed. Women and children eaſily broke the clods of this ground, which was thereby at once brought into good order; the roots of all the wild plants having been effectually cut through, and their ſeeds deſtroyed by the fire. My wheat, by this means un-incumbered with noxious productions of any kind, flouriſhed well, and yielded an excellent crop; as alſo did ſuch other parts of my land as were under corn. The ſucceſs of this year revived my hopes. I now perfected my method of making artificial dung, which, as I have already obſerved, proved of infinite ſervice; and, for manuring my more diſtant lands, I built upon them perpetual kilns, which have always ſupplied me with a ſufficient quantity of aſhes.

"This year I began to plant white mulberries, in order to feed ſilk-worms, and make the inhabitants acquainted with the management of them. I have ſince continued to make plantations of this kind every year, and find them anſwer perfectly well, eſpecially in light ſoils. Several of them are an uſeful embelliſhment to proper parts of my improved lands, and I have alleys of them, which, though not ſuffered to run up high, form a very pleaſing proſpect.

"In 1751, I again ſucceeded perfectly well in my new method of paring and burning. All my cultivated lands now yielded very good crops; and that in particular which I had broke up laſt year, and ſince dunged properly, that is to ſay with half the quantity commonly uſed upon ground in general, produced more than any other equal ſpace had yet done. From this time I continued to dung all my grounds which were broken up in this manner, every alternate year.

"My improvements were now become ſo extenſive, that I was again obliged to increaſe the number of my ſervants, and of my ploughing cattle. The ſame thing happened more than once after this; but I ſhall not mention it any more. My cattle too, of different kinds, had multiplied ſo much, that I had no longer room for them in the old farm yard, or buildings belonging to it; but plainly ſaw, that if my improvements were enlarged every year in the manner they had hitherto been, I ſhould ſoon want more yards, and more buildings, to keep them in. I accordingly marked out proper places for this purpoſe, and drew plans for more ſpacious buildings.

"As the cattle in this country are ſmall, I bought ſome of a larger ſize in Poictou (from whence we generally have our working beaſts), and particularly a fine bull, to try if I could mend our breed, and thereby have of my own oxen ſtrong enough for the plough; by which means I ſhould ſave the expence of buying them elſewhere. I have not yet ſucceeded in this, ſo far as I could wiſh; probably becauſe my paſture is not yet good enough. However, my bullocks, proceeding from this race, are much ſtronger and bigger than thoſe I had before, though not large enough to be yoked to the beam, but only before or with others.

"The ground which I broke up in 1752, was pared and burnt in the ſame manner as that of laſt year, and produced an equally good crop. My other corn lands did the ſame; and I have ſince continued, and ſtill continue, at the time of my writing this, to break up a parcel of heath, or other waſte-ground, every year. The ſucceſs has anſwered; ſo that my improved lands now yield me every kind of corn which this country produces. Turky-wheat, buck-wheat, and millet, have done extremly well in ſome parts of them; and ſo have flax, hemp, and other productions ſuited to the different qualities of the ſoil. In ſome places I have ſowed, at different times, ſeveral ſorts of trees, ſuch as the oak, the beech, the cheſnut, the fir, and others, all of which thrive wonderfully. I have likewiſe planted new vineyards, and find them anſwer perfectly well. All theſe trials convince me more and more, that the very beſt way of preparing land, is by burning it, as I have already ſaid more than once. Thoſe who were formerly the readieſt to blame my undertakings, now ſee their error, and commend them.

"During this ſame year 1752, as well as in the courſe of the following, I drained ſeveral marſhes, and improved other pieces of uncultivated ground, which, not being of the heath kind, or proper for paring, were broken up, and fitted for their reſpective crops, whether of corn, or of other plants, as will be more fully related in the ſecond part of this account. I likewiſe ſowed in theſe, as I had done before in other places, trees of every kind, ſome of which have ſucceeded, and others failed, according to the ſoil, and the manner of preparing it. This alſo will be more fully noticed hereafter, when I ſhall ſpeak particularly of the different methods of raiſing trees from their ſeeds; and of the means of obviating the three chief difficulties, which muſt of neceſſity be guarded againſt or removed,

before

before one can properly ſet about breaking up any ſort of ground; theſe are, water, ſtones, and large roots; each of which I have found it neceſſary to get rid of, before I could rightly begin any of my improvements.

" I endeavoured this year to make ſome progreſs towards perfecting my inſtruments of huſbandry; my new buildings went on according to the plan I had laid down, and were extended from time to time, in proportion as the products of my enlarged improvements, and the increaſe of my ſtock of cattle, required more room. I likewiſe tried to mend the breed of horſes in this country, where their chief fault is, that they are too ſmall

" My ſheep were alſo of too ſmall a ſize, and yielded but little wool; which indeed is the caſe throughout all this province. I therefore got from Lower Poictou, in the year 1753, two fine rams, of the large kind, called Flemiſh; by which means my lambs are much ſtronger than any other in theſe parts. Several of the males are almoſt as large as their ſires, and I have given ſome of them to my neighbours for rams. They have produced a baſtard breed, which increaſes apace, and, though not ſo large as the Flemiſh, yields more and better wool than our former breed. I got rid of all my old ſheep by degrees, and have now a well-ſized flock: nor do I doubt but that if I could conveniently have purchaſed a whole flock of theſe large ſheep, their breed might have been preſerved without degenerating, and increaſed ſo as to ſupply the place of our preſent inferior ſpecies; for our uncultivated lands would feed a much greater number of ſheep than we even attempt to raiſe.

" In 1755, I diſcovered lime-ſtone upon my own land. This proved a conſiderable ſaving; for I had hitherto been obliged to fetch my lime from a diſtance of near twelve miles. This ſtone, if properly ſearched for, may often be found in places where it is not ſuſpected to lie. It is eaſily known, by putting a piece of it into the fire till it be calcined, and then diſſolving it in water. This diſcovery, in conſequence of which I built a proper kiln, has enabled me to carry on my buildings with leſs expence than before, and is of ſignal ſervice in affording an excellent manure for my land.

" I began this year to give premiums for agriculture to the inhabitants of my eſtate. They were inſtituted the year before; and I had long uſed my beſt endeavours to inculcate a general love of induſtry, and a reliſh for improvements. My ſucceſs had induced ſeveral others, both landlords and farmers, to follow my example, as well in amending their already cultivated lands, as in the breaking up of new grounds. I aſſiſted them in their undertakings, giving inſtructions to ſome, lending ſeeds to others, and money and tools to ſuch as were honeſt, and wanted them. The better to encourage them all, I had given rewards every year to thoſe who diſtinguiſhed themſelves moſt, and allowed my tenants ſixteen ſhillings for every acre of new ground broken up by them: a regulation which ſtill ſubſiſts.

" To fix theſe people in the induſtrious diſpoſition to which I at length had brought them, no method ſeemed to me more proper than to take them on the weak ſide of almoſt all mankind, intereſt and vanity. Accordingly, I notified in the month of January 1754, that I would diſtribute every year, beginning on the next enſuing feſtival of the Aſſumption, two premiums for agriculter; one, to the perſon who ſhould raiſe the fineſt crop of wheat, and the other to him who ſhould have the beſt field of rye. Each of theſe premiums conſiſts in a ſum of money, not inconſiderable for the country where it is given, and a ſilver medal, engraved for the purpoſe, of the ſize and value of a crown piece. Theſe were, I believe, the firſt premiums ever propoſed in France for this moſt uſeful object; though many have been given for much leſs intereſting concerns. On one ſide of this medal is a ſheaf of corn, with two ſickles, a ſcythe, and a flail; over which are the words, *Premium for Agriculture*, and underneath the date. On the other ſide are my arms, with this inſcription round them: *To excite to Induſtry the Inhabitants of*, &c. I would not put the goddeſs Ceres of the ancients, or any emblematical figure upon this medal, becauſe, in the firſt place, the ignorant peaſants would not have underſtood its meaning, and in the next, ſome of them might perhaps, hereafter, take it for the repreſentation of a ſaint, and honour it as ſuch; by which means, what I intend only for an object of utility, would become a ſource of ſuperſtition or idolatry.

" A candidate for theſe premiums muſt have at leaſt two acres of land ſowed with either wheat or rye: they are given to the fineſt crop as it ſtands, to avoid all tricks; and if two crops are deemed equally good, the worſt ſoil has the preference. When both the crops and the ſoils are alike, the largeſt extent of ground is entitled to the reward. The inhabitants of the place, in general, meet at the pariſh church on the day appointed; and, after divine ſervice, chooſe from among themſelves five who are not candidates, to inſpect all the fields of corn, and mark thoſe which they think the fineſt. On the next Sunday or holiday, they make their report to the ſame aſſembly. If any one complains that his corn has been unjuſtly paſſed over un-noticed, proper perſons are immediately ſent, to examine whether the complaint be juſt. The aſſembly then appoint the ſame five as before, or others if they pleaſe, to go and inſpect again, with the utmoſt care, the fields which they had marked, and to judge which two of them, one of wheat, and the other of rye, beſt deſerve the premiums. On the next Sunday or holiday they declare their opinions to a general aſſembly of the pariſhioners, as before; and, if no objection be made by any of thoſe whoſe corn has been marked, this aſſembly adjudges the premiums accordingly: but if any one of them appeals, other proper judges are immediately choſen, and directed to inſpect the ſpot. On the next Sunday or holiday, till which the deciſion of the premium is, in this caſe, of courſe put off; theſe laſt examiners make their report, and the matter is then determined. All the people thus ſent by the aſſembly, are paid at my expence. In conſequence of the deciſion of the inhabitants, the premiums are delivered publickly on the feaſt of the Aſſumption, after the ſervice at church is over. Thoſe who win them, wear the medal, for a year only, faſtened with a green ribbon to a button-hole of their coat, and have, likewiſe for that time, a diſtinguiſhed ſeat in the pariſh church. Theſe marks of diſtinction ceaſe at the end of the year, when others ſucceed to them; but the medal remains the property of the perſon to whom it was adjudged. He may diſpoſe of it as he pleaſes: yet, though he is no longer allowed to wear it on the outſide of his cloaths, there has not been a ſingle inſtance of any one's ſelling his medal. They all keep it as a badge of honour.

"These rewards have been productive of so much good, and have raised so extraordinary an emulation among my tenants, that I cannot but advise every gentleman to practice the same method upon his estate. I intend to institute some others, for different productions; and as I am far from having a sufficient number of people to manage all my lands, if the whole of them was under culture, I have long thought of giving gratuities to such as shall have a child within the first year of their marriage, to continue this allowance to them so long as they shall have a child from year to year, and to allot a pretty considerable sum for the family which shall have most children. Some may, perhaps, think these encouragements for propagating the human species odd, and even superfluous: but they will be of a different opinion when informed, as they may be by the ministers of most country parishes, that many peasants are unwilling to get children, or at least do not choose to have more than a very small number, when they might have a numerous offspring. If my abilities were equal to my will, I should already have formed all these useful establishments. It is generally allowed, and experience has particularly demonstrated it upon my estate, that an increase of culture produces an increase of inhabitants; and that wherever there is room for two, with the means of subsisting them, a marriage will ensue: but at the same time that this means of increasing population is encouraged by a more extensive culture of the earth, I see no reason why proper methods should not be used to induce men likewise to concur in the same laudable end.

"Ever since the year 1756, I have continued all my undertakings, and with the same success as before. Those who saw the condition of my estate when I first came to it, in the year 1737, now scarcely know again a single spot of it; so much is the face of the country changed. My mansion-house, which was formerly surrounded with dreary wastes, vast commons, and unbounded heaths, now stands in the middle of well cultivated fields; my improvements are become considerable both for extent and value; producing all sorts of grain, and natural as well artificial grasses. I have dispersed in them all kinds of fruit-trees, and divided them into fields of proper sizes, separated by good ditches planted with quick hedges. Alleys of limes, poplars, white mulberries, chesnuts, and various other trees, besides being a considerable embellishment to the whole, afford convenient passes from one field to another, yield food to cattle, and are sown from time to time. I turn every thing to profit; even my driest soils. Many of my marshes are drained, and yield good crops. All my meadows, by reason of their great extent, are not yet brought to the state in which I wish to see them; though a great part of them now produces excellent hay. I have mowed some of them twice a year, and hope by and by to do the same to others; for I intend to water them all, by making dams and sluices in the brooks and rivulet which passes through them.

"My vineyards are in good order; and my woods, which are now in regular cuttings, thrive perfectly. Some of these, which I have raised from the seed, have grown so prodigiously, that a stranger would think them much older than they really are. I have made some large reservoirs of water, and several ponds, entirely new, besides repairing the old ones. All these have succeeded, and yield good fish. A quarry of mill-stones, formerly abandoned, now turns to good account, and I have discovered several quarries of free-stone.

"I have been obliged to make several bridges over the brooks and rivulet which divide my meadows and marshy grounds, and have carried my roads as far as my improvements extend. Some of these roads lie over hills, which could not be avoided; though others have been cut through, at a great expence. Most of my outhouses, which are pretty spacious for all my cattle and all the produce of my land, with proper buildings for poultry, barns, granaries, &c. are finished; and I have built farm-houses with the stones which it was necessary to take off the lands, in different parts of my improvements, and settled in them young men, who are now married, and have children. Though my barns are very large, and not few in number, I have the pleasure to find that they would not contain all my last year's crop of corn: a satisfaction which I hope to enjoy still more amply in the next and following years.

"Thus my estate, which formerly yielded scarce any thing, now affords every necessary for food and raiment. When there, I can, truly speaking, keep a very good table, and be decently cloathed, with only the produce of my own improvements. I have no occasion to buy any thing, except salt, sugar, and spices. My farmers have followed my example, so far as their means, and the helps which I have given them, have permitted.

"These improvements have, undoubtedly, cost me a great deal of money; but my income from them will soon be proportionably increased; besides which, it is proper to observe, that few lands will require so great an expence to break them up, as mine have done; owing to the uncommon stubbornness, inequality, and unkindliness of the soil: nor will it often be necessary to cut through hills in order to make roads, to lay causeys over quaking bogs, or to erect so many new buildings: though, even if all these difficulties should occur, I would still advise gentlemen to undertake the improvement. If they follow the directions here given, and profit by my errors, so as not to comit the like, I can assure them of success, at a much less expence than it has cost me, who have thoroughly paid for my apprenticeship. I can also promise, that they will lay their money out at better intrest, and on better security, in this, than in any other way: besides which, they will have the heart-felt satisfaction of contributing to the prosperity of their country, to the increase of population, and to the enriching of others, at the same time that they enrich themselves.

"I have already said, that when I began my improvements, two and twenty years ago, a third part of the farms in my parish were untenanted, for want of farmers who would rent them; that most of the inhabitants of my estate were very poor, and did not, in general, reap corn enough to support them half the year; that they were grown so indolent, that rather than cultivate their ground, which would have afforded them a maintenance, they chose to beg, like vagrants, in the neighbouring districts. Now their situation is very different, and they are no longer in that deplorable condition. They are become industrious, live by their labour, and beg no longer: they would even be at their ease (a happiness which I shall do my utmost to procure them), were it not for obstacles beyond my power to remedy. The

parish

pariſh now reaps more corn than it conſumes; ſo that the farmer here is enabled to ſell at the very markets where he uſed to buy. All my farms are tenanted; not a houſe on my eſtate is empty, and if I build a new one, it is immediately filled; in ſhort, the number of inhabitants in this pariſh, for I have an exact liſt of all of them, is double what it was in 1737. Such is the hiſtory of my improvements, and ſuch are the effects with which they have been attended." *Memoir ſur les Defrichemens, par.* II.

COMPOST, an uſeful ſort of manure, conſiſting of earth, dung, lime, clay, &c. according to the nature of the ſoil, well mixed and rotted together, till it forms one united maſs. *See* DUNG-HILLS.

CONE-WHEAT, a ſpecies of wheat, called in ſome parts of Somerſetſhire, blue ball. Some of the ears of this wheat have awns, and others none. *See* Plate IV. Fig. 5.

CONIFEROUS, an epithet applied to ſuch trees as bear acones, as the fir, pine, cedar, &c.

CONSOUND, the ſame with bugle. *See the article* BUGLE.

CONSUMPTION, a diſeaſe incident to horſes, conſiſting in a waſte of muſcular fleſh, attended with a ſlow fever.

When a conſumption proceeds from a defect in a horſe's lungs, or any principal bowel, the eyes look dull; the ears and feet are moſtly hot; he coughs ſharply by fits; ſneezes much, and frequently groans with it; his flanks have a quick motion; he gleets often at the noſe, and ſometimes throws out a yellowiſh curdled matter, and he has little appetite to hay, but will eat corn, after which he generally grows hot.

As to the cure, one of the principal things is bleeding in ſmall quantities, a pint, or pint and half, for ſome horſes is ſufficient, which ſhould be repeated as often as the breath is more than ordinarily oppreſſed. Pectorals may be given to palliate preſent emergent ſymptoms; but as diſſections have diſcovered both the glands of the lungs, and meſentery to be ſwelled, and often indurated, the whole ſtreſs lies on mercurial purges, and the following ponderous alteratives, given intermediately.

Take native cinnabar, or cinnabar of antimony, one pound, powdered very fine, and add the ſame quantity of gum-guaiacum and nitre: give the horſe an ounce of this powder, twice a day, wetting his feeds.

The ſpring graſs is often extremely ſerviceable, but the ſalt-marſhes are to be preferred, and even to be more depended on than medicines; for great alterations are thereby made in the blood and juices, and no ſmall benefit ariſes from open air, and proper exerciſe.

But it may be worth obſerving, that a horſe frequently relapſes after appearances of amendment; when a yellowiſh gleet, or curdled matter, runs from his noſe, and he grows emacited, is much addicted to ſweat, heaves much with a reduplicated motion, and has a ſhort rattling cough; under theſe circumſtances there can be little hopes of his recovery, or any future ſervice from him, conſequently, to ſave farther expences, the beſt way would be to diſpatch him as an incurable. *Bartlet's Farriery, p.* 76.

CONVOLVULUS, the ſame with bind-weed. *See the article* BIND-WEED.

COOM, the ſoot that gathers over the mouth of an oven; alſo a compoſition of tar and greaſe, with which the axle-trees and boxes of the wheels of carriages are daubed or ſmeared over, in order to leſſen the friction.

COOP, a tumbrel or cart encloſed with boards, to carry dung, ſand, grains, &c. which would otherwiſe fall out.

COOP, likewiſe ſignifies a pen, or encloſed place, where lambs, poultry, &c. are ſhut up in order to be fed.

COPPICE, low woods, cut at ſtated times for poles, fuel, &c.

"If you are to plant a coppice, ſays the ingenious Mr. Liſle, it is a good way to ſet your plants in trenches, as one raiſes quickſet hedges, and not to ſow ſeeds, for they are tedious in coming forward, and will tire one's patience in weeding them. I would not ſet above four plants in twelve feet ſquare, and at regular diſtances, ſo that the benefit of ploughing might not be loſt; and then at ſix or ſeven year's growth I would plaſh, by laying the whole ſhoot, end and all, under the earth in the trenches, which would not therefore be choaked, but ſhoot forth innumerable iſſues: this, by great experience, oak, aſh, hazle, and withy, will do.

"In our parks we never ſet leſs than an hundred plants in a double chaſed lugg; and if the earth turned up ſuch rubbiſh and ſtoney ſtuff that the edge of earth on which they are to plant, is too narrow for a double chaſe, then they always ſet eighty plants on a ſingle chaſe in a lugg.

"I obſerve the ſedgy graſs comes not up in felled coppices the firſt ſummer; conſequently the young ſhoots have a year's ſtart of that graſs; the next ſummer the ſedgy graſs comes up, and grows ancle high, equal with the two year's ſhoots: but what harm can it then do to the wood? The third year the ſedgy graſs dies, and you ſee no more of it. I ſpeak this, in anſwer to the countryman's objection, who pleads for putting ſome ſort of cattle into coppices to keep down the ſedge, which he pretends otherwiſe will choak and damage the plants. I have experienced this to my coſt.

"It was May the ſixth, in the year 1701, that I bought ſome yearlings; and I aſked the farmer, if I might not put them in the coppice till midſummer; the farmer ſaid, not yet, by any means, for fear they ſhould be oakered, that is, leſt they ſhould bite off the oak-bud before it came into leaf, which might bake in their maws and kill them; but after the oak-bud was in leaf, it would be ſafe enough. The higher coppices are fit for yearlings, and the coppices of the laſt year's growth for hog-ſheep in winter. My ſhepherd ſaid, what the farmer obſerved as to the oak-bud was true; but he thought that the year was ſo backward, that they were not yet come out, and ſo there could be no danger at preſent. Farmer Elton ſaid, his father had loſt abundance of yearlings by the oak-bud, by putting them into the coppices while that was out. I have ſince experienced the ſame, and I have ſince remarked the ſame.

"It is a common ſaying, that calves will not crop in woods: but I put ſix calves in my woods, in November, which very much cropt the yearling-ſhoots. All huſbandmen I told of it very much wondered at it; but the reaſon to me was clear, viz. On firſt putting them in there came three or four days hard froſt, with a ſhallow ſnow, and a rime that laid on the bennetty graſs, ſo that they could not come at the ground, but only met with brier leaves, of which, though I had plenty, they

were but thin diet to depend on altogether; yet together with other pickings, would have been a noble maintenance for them, if they could have come at the rowet: this ſtreightneſs of fodder brought them to the neceſſity of cropping the young ſhoots, which they afterwards continued to do, having got the habit of it, and finding, when the weather came ſevere, the ſhoots to be toothſome, though the rowet in the coppices would have been ſufficient.

"For a general rule, newly weaned calves are leſs hurtful to newly cut ſpring-woods than any other cattle, eſpecially if there be abundance of graſs; and ſome ſay, colts of a year old will do no harm: but the calves muſt be permitted to ſtay a while longer, and ſurely the later you admit beaſts to graze the better.

"Letting coppice-wood grow to ſixteen or ſeventeen years growth is of great ſervice to young heirs, becauſe by ſo many years growth their backs are caſe-hardened, and able to withſtand the cold, when the coppice is cut, and they muſt ſtand naked, whereas, when coppices are cut at ten and eleven years growth, the barks of the young heirs are ſo tender, that they are ſtarved with cold air and winds. Ivy itſelf, ſays Evelyn, the deſtruction of many a fair tree, if very old, and taken off, does frequently kill the trees by a too ſudden expoſure to the unaccuſtomed cold.

"When coppice-wood is of fourteen or fifteen years growth, it will yield a better price in proportion than young wood, becauſe it will be applicable to more uſes, and particularly in the cooper's buſineſs; for he will uſe the withy and ſome of the aſh for hoops and wine hogſheads; another part of the aſh may ſerve for prong-ſtaves, rake-ſtaves, and rath-pins for waggons, and the reſt may be parcelled out for hurdle and ſtake-rods.

"Oaken ſtems of fourteen years growth are, in my woods, which in a great meaſure conſiſt of them, as high as the aſh or withy, and meaſure more in the diameter; for oaken ſtems are ſtronger at root, and will hold growing longer than aſh, withy, or hazle. When hazle grows ſpriggy in the body, and ſhoots forth from the ſides of the back, it is a ſign that it has given out, and done growing at the top.

"Coppice-wood, in hedging and hurdling, wears much better and longer, if cut between Michaelmas and Chriſtmas, but ſells beſt in faggots, if cut between Chriſtmas and Lady-day, becauſe it ſhrinks leſs, and is much ſwelled, and looks beſt to the buyer. The method at Crux-Eaſton, and the hill-country adjacent, is only to oblige the buyers to rid the coppice by Midſummer; they think the coppices are not harmed, if rid by the time the Midſummer-ſhoots ſpring up, but they had not rid this year, 1697, by the latter end of July.

"It is obſerved, that coppice-wood, cut for hedging at the latter end of winter, will not endure ſo long by a year as that which is cut at the beginning of winter: which, as I believe, may not only be, becauſe the wood late cut, is cut after the ſap is riſen, or attenuated by the ſun, but alſo oftentimes becauſe it is not cut long enough before ſuch rarefaction is made; for, if a tree, or a cyon cut to be grafted, as Quintery affirms, will endure many weeks of the winter out of the ground, or without being grafted, and, when ſpring ſhall come, it will by virtue of the ſap inherent in it, when attenuated put forth buds for ſome time, till it dries away; ſo it follows, that the ſap inherent always in the ſtem of the wood, if not cut ſo early as to have long time to dry, may be put into motion at ſpring, ſo as to effect the abovementioned inconvenience; therefore I hold hedging-wood and fire-faggots ſhould be cut in October.

"It is a common practice of huſbandmen to fell their hedge-rows, and ſmall brakes within the grounds, thoſe years they ſow the grounds with wheat; but ſuch perſons ought well to conſider, firſt, whether ſuch land, after the wheat is off, will not bear a rowet too long for ſheep to eat, and, if ſo, great cattle muſt be put in to eat up the long rowet, and the ſooner the better for their tooth; and then attendance muſt be given by a cow-keeper by day, before the harveſt is in, and conſequently the wages dearer, and when you may have many other offices to employ ſuch a perſon in: therefore, in ſuch caſe, my advice is to let the hedge rows ſtand till after the wheat crop be got in, when great cattle may be ſuffered to feed down the rowet without prejudice to the hedge-rows, and at that time of the year ſuch graſs is wanted by night; and, during the future three crops, it is to be ſuppoſed the rowet will not be ſo large, but ſheep may overcome it, nor will they very much prejudice the young wood." *Liſle's Huſbandry, vol.* II. *p.* 245.

In raiſing coppices, great care ought to be taken that the wood they are to be compoſed of be ſuch as is proper for the ſoil you raiſe them on, and that it be proper for the uſes you deſign to ſell it for, which you muſt be regulated in by the vent you have; and let the profits reſulting from your under-wood regulate the thickneſs of your ſtandards; for in proportion as they are thicker or thinner, they will do more or leſs injury to your under-wood. You ſhould likewiſe conſider at what growth you can ſell your under-wood; only remember that the older and taller your under-wood is, the betterit is both for fuel, and for what ſtandards you leave, becauſe they will be the taller and ſtraiter, by being forced up by the wood that grows about them; though a deep ſoil contributes much to their ſpring. It is alſo neceſſary, about the time of your felling, to lay out your ſeveral falls, that you may have an annual ſucceſſion, to yield a yearly profit. But though the ſeldom felling of coppices yields the more and better wood; yet the frequent cutting of it makes it thicken, and gives room for the ſeedlings to come up. If many trees grow in the coppice that is to be cut down, fell both them and the underwood together, cutting off the ſtubs as near the ground as convenient, and thoſe of the underwood a-ſlope and ſmooth, and not above half a foot from the ground; and ſtock up the roots of the timber-trees, if they ſend forth no ſhoots, in order to make room for ſeedlings and young roots to grow.

The under-wood may be cut from the beginning of October to the latter end of February; but February is the beſt month to cut wood in, where you have but a ſmall quantity to fell, that you may do it before the ſpring comes on too much: take great care to prevent the carters from bruſhing againſt the young ſtandards, and let all your wood be carried out by Midſummer, and made up by the end of April at the fartheſt; for if the rows and bruſh lie longer unbound or unmade up, it will ſpoil many of the young ſhoots and ſeedlings. If the winter before you fell, you encloſe it ſo as to keep all cattle out of it, your care and trouble will be well recompenſed.

A. Hulett Sculp.

Your elder underwood may be grazed about July, or in winter, but, for a general rule, newly weaned calves are the leaſt prejudicial to new cut wood, where there is abundance of graſs; and ſome ſay colts of a year old; but then they muſt be drove out by the beginning of May at fartheſt. However, if nothing at all be ſuffered to come in, it will be better. In this every man's experience muſt direct him.

If your woods happen to be cropt by cattle, it will be better to cut them down, and they will then make freſh ſhoots; whereas what has been bit by the cattle, will be otherwiſe ſtunted for ſeveral years before it will take to its growth. *Mortimer's Huſbandry, vol.* II. *pag.* 69.

CORD *of Wood*, a certain quantity of wood for fuel, properly ſtacked up; ſo called becauſe it was formerly meaſured with a cord. The dimenſions of a ſtatute cord of wood are eight feet long, four feet high, and four feet broad.

CORE, a diſorder incident to ſheep, occaſioned by worms in their liver, reſembling a plaice, or flounder.

A ſheep, if chiefly fed with hay, will live a year after being affected with this diſtemper, by which time he will have a water-bladder as large as an egg, under his throat; at the ſame time his eyes, mouth, and gums, will be white.

If any ſheep in a flock core during the winter, it will be eaſily ſeen at ſhearing-time; for ſuch ſheep will be poorer than the reſt; their wool alſo will run into threads, twiſting together at the ends, and look ſomewhat like teats. The laſt particular is not however a certain ſign of a ſheep's being cored; for ſometimes the wool of very ſound ſheep will be apt to run together into threads; and the finer the wool the more apt it is to twiſt together in that manner. There is no method of curing this diſtemper hitherto known. *Liſle's Huſbandry, vol.* II. *pag.* 207.

CORIANDER, the name of a plant formerly much cultivated in England; but at preſent little of it is ſown.

The ſeeds ſhould be ſown in autum on rich land; and when the plants are come up, they ſhould be hoed out to about four inches diſtance, every way, clearing them from weeds. By the above management, the plants will grow ſtrong, and produce a greater quantity of good ſeeds. *Miller's Gard. Dict.*

CORN, a general name for grain that grows in ears, not in pods, as wheat, barley, &c.

If corn be lodged, it may be cut before it is quite ripe; and if blighted, it cannot be cut too ſoon. But if neither of theſe accidents happen, both wheat and barley ſhould be ſuffered to ſtand till full ripe. The grain will alſo grow plumper by being left a while in the field after cutting, to take the dew; but the ſtraw will be injured by it; nor muſt it by any means be laid up damp in the mow, leſt it heat, and become what is called mow-burnt; and perhaps take fire. A great number of weeds will produce the ſame effect, if the corn be houſed before their ſtalks are ſufficiently withered.

A correſpondent of the authors of the Muſeum Ruſticum tells us, that in the year 1763, he had twenty acres of barley, which was rather weedy at harveſt: on which account he was deſirous of giving it as much field room as he could conveniently; but the weather promiſing to be very wet, he was obliged to cart his barley, which he put into the bay of a large barn.

Whilſt this work was going forward, he was called away, and in his abſence his ſon got a horſe upon the mow to tread it; by which means, the weeds, not being thoroughly dry, cauſed the barley to heat to ſo violent a degree, that he was very apprehenſive of its firing.

"My men, adds he, were in a violent hurry to get it out of the barn; but this I would by no means conſent to. I however ordered one of them to get upon the mow with a cutting-knife, and cut in it a round hole like a well. He began the work; but in about five minutes, being almoſt overcome by the heat, I ſent another to relieve him; and thus they worked ſpell and ſpell, till they got to the bottom.

"This round hole ſaved my barley, and perhaps my barn too; for it formed, as it were, a chimney or flue, to carry off the heat." *Muſeum Ruſticum, vol.* III. *p.* 365.

For the method of preſerving corn after it is threſhed, *ſee the article* GRANARY. And for preſerving it in the ſtraw, *ſee* REEK.

CORN-CROWFOOT, a weed very common among the corn. It has an upright ſtalk; the leaves are of a pale green, and cut into long, narrow, acute ſegments. The flowers are much ſmaller and paler than the crowfoot of the paſtures: but the ſeed-veſſels are the moſt remarkable, being covered all over with prickles. *See* Plate V. fig. 33.

CORN-FLAG, a very troubleſome weed, multiplying exceedingly by its roots. It has a round compreſſed tuberous root, which is of a yellowiſh colour, and covered with a brown furrowed ſkin, like that of the vernal crocus. From this root ariſes two flat ſword-ſhaped leaves, which embrace each other at their baſe; and between theſe ariſes the flower-ſtalk, which grows near two feet high, having one or two narrow leaves embracing it like a ſheath. This ſtalk is terminated by five or ſix purple flowers, ſtanding above each other at ſome diſtance, and ranged on one ſide of the ſtalk; each of theſe has a ſheath, which covers the flower-bud, before it expands, but ſplits open lengthways when the flowers blow, and afterwards ſhrivels up to a dry ſkin, which remains about the ſeed-veſſel, till the ſeeds are ripe, which is in the beginning of Auguſt. The flowers come out in the beginning of May, or in June. Some of theſe flowers are white, and others fleſh-coloured.

Corn-flag is extremely difficult to root out, as every part of the root will grow. The beſt manner of extirpating it is that already mentioned under the article colts-foot. *See* COLTSFOOT.

CORN-MARYGOLD, the name of a very troubleſome weed, of which there are two ſpecies, one common in corn-fields, and the other in moiſt paſtures. The leaves of the firſt ſort embrace the ſtalks, the upper being jagged, and the lower indented like a ſaw. The ſecond is, by C. Bauhine, called the greater wild daiſy, with a leafy ſtalk. It riſes with ſtalks near two feet high, garniſhed with oblong indented leaves, which embrace the ſtalks with their baſe. Each of theſe ſtalks is terminated by one white flower, ſhaped like that of the daiſy, but four times as large. It flowers in June. *See* Plate V. fig. 34.

The corn-marygold has a perennial woody root, which ſtriking deep requires a conſiderable quantity of food, and therefore muſt be a great enemy to the corn. Conſiderable pains muſt be taken before this weed can be extirpated, as it is highly probable, that, beſides multiplying by its roots, its ſeed will grow, if plowghed in, as that or

the

the garden marygold will do when dug in. Deep and repeated hoeings are therefore neceſſary, before it runs to ſeed.

CORN-PARSLEY, the name of a low branching plant common among corn. The branches grow thick together, and are knotted and crooked. The flowers grow cloſe together after the manner of parſley, and are of a white colour inclining to yellow. The ſeeds are large in proportion to the plant; and are ſet about with little crooked briſtles; which makes them adhere to the ſtockings in great plenty, when the ſeeds are ripe; which is generally about harveſt. *See* Plate V. fig. 35.

CORN-WORM, the inſect lately obſerved in France to be ſo very deſtructive to corn. *See the article* BUTTERFLY.

CORNER-TEETH, the teeth which appear when a horſe is coming five years old. *See the article* AGE.

CORONET, the loweſt part of a horſe's paſtern, which runs round the coffin, and is diſtinguiſhed by the hair which joins and covers the upper part of the hoof.

COSH, the ſame with pods. *See the article* POD.

COSSART, or *Coſſet Lamb*, a lamb left by its dam's dying before it is capable of ſhifting for itſelf; or it is a lamb taken from a ewe that brings two, three, or four lambs at a yeaning, and conſequently is incapable of bringing them all up. The word is alſo applied to a colt, calf, &c.

In either of theſe caſes, if there be not another ewe at liberty to ſuckle it, it muſt be brought up by hand, or periſh. By an ewe at liberty is meant one that has, by ſome accident, loſt her lamb, and has milk enough to ſuckle a lamb yeaned by another.

COSTIVENESS, a complaint to which horſes are often ſubject; ſometimes occaſioned by violent and hard exerciſe, eſpecially in hot weather; and ſometimes by ſtanding long at hard meat, without graſs, or other cleanſing diet, and with very little exerciſe.

The cure for this complaint is eaſy, only by giving him an open diet for ſome time; and if any thing more is wanting, lenitive mild purges are the moſt likely to ſucceed. Such as Glauber's ſalts with lenitive electuary, four ounces of each, diſſolved in warm ale or water, and repeated every other day. This, with ſcalded bran given every day, will ſoon remove the complaint, and carry off the viſcid ſlime engendered in the guts, which is generally the cauſe of his coſtiveneſs.

But there is another kind of coſtiveneſs in horſes, which is much harder to be removed, viz. that which ſeems to be natural, or grown into a habit. We find ſome very good horſes liable to this diſorder; and, when it is of long continuance, they are apt to grow lean and emaciated, feel hot and dry, their hair ſtaring, and there is danger of ſome approaching ſickneſs.

This diſorder is not eaſily removed; nor is it often neceſſary to bring ſuch horſes into a contrary habit; for where this is natural, it may proceed from a more than ordinary ſtrength and rigidity in the ſmall fibres of the ſtomach and guts, which makes them digeſt their aliment well, and retain their excrements longer; and when ſuch a habit can be kept within any proper medium, the horſe will continue in ſtrength and vigour, without any inconvenience; and it is obſervable, that theſe horſes are, for the moſt part, able to endure great fatigue and labour. However, it is proper to give ſuch horſes, at all convenient times, an opening diet. For if this habit happens, by any accident, to grow into an habitual coſtiveneſs, ſo as to produce ill effects, as heat, dryneſs of the conſtitution, little ſcabby eruptions over the ſkin, and a rough coat, it will then be neceſſary to remove it in ſome degree, which cannot be done but by a continual uſe of emollients, joined by a looſe opening diet.

Purging is here alſo neceſſary, and ought by all means to be complied with; but purging in the common way with Barbadoes or other plantation aloes, ſeldom has any great effect longer than the purge is working; for when that is over, the ſame habit of coſtiveneſs generally returns as ſtrong as ever. Scalded bran, and the common opening diet, ſeldom makes any great alteration in theſe horſes. The aloetic purges will ſcarcely work, eſpecially if they are made ſtrong, for they then chiefly run off by urine, which does the creature little ſervice in this caſe. But after the common purges have failed, the following will ſucceed beyond expectation.

Take ſuccotrine aloes, ſix drams; ſpermaceti, half an ounce; fœnugreek-ſeeds in powder, two ounces? make the whole into two balls, with a ſufficient quantity of honey, or common treacle, and give them in a morning faſting.

Let the horſe have ſcalded barley inſtead of ſcalded bran, and the liquor of the barley for his drink, milk warm. This will work very gently, where ſtronger purges have little other effect upon coſtive horſes than to gripe and make them ſick. It ought to be repeated once in four days, and may be continued till he has taken ſix doſes. Let him have an ounce of fœnugreek-ſeeds once a day, in one of his maſhes, and when the purgation is over, continue the uſe of the fœnugreek; and ſometimes gives linſeed in the ſame manner, either in his dry or moiſt feeds, until the horſe grows ſmooth and well coated, and his dung moiſt and in good order. *Gibſon's Farriery, vol.* II. *p.* 134.

COTYLEDONS, rinds, or huſks.

COUCH-GRASS, *quick-graſs*, *knot-graſs* or *dog-graſs*, is one of the worſt of weeds among corn, and one of the moſt difficult to extirpate in arable land; every joint of its long creeping roots being capable of ſoon producing a new plant, after thoſe roots have been broken by the plough. The uſual way of deſtroying it, is by laying the land fallow in ſummer, and frequently harrowing it well over, to draw out the roots, every piece of which ſhould then be burnt, for the reaſon already mentioned. Where this is carefully done, the ground may be ſo well cleanſed in one ſummer, that the remaining roots will not do any great injury to the enſuing crop: but the beſt way is to ſow the land in which this weed prevails with ſuch plants as require the horſe-hoeing culture. The blade of this graſs is ſo rough, that the cattle will not feed upon it when green.

COVERT, ſheltered, not open, not expoſed.

COUGH, a convulſive motion of the lungs, being an effort of nature to throw up ſome offending matter.

Horſes are very ſubject to coughs, which are ſometimes occaſioned by colds, and often by the idjudicious treatment of an inflammation of the lungs; the conſequence of which is often ſettled habitual coughs, which frequently degenerate into aſthmas, and broken wind.

Nothing has more perplexed practitioners than the cure of ſettled coughs; the cauſe of which, perhaps, has

has been their want of attention to the different ſymptoms which diſtinguiſh one cough from another; for, without ſtrict obſervance thereof, it is impoſſible to find out the true method of cure.

Thus, if a horſe's cough is of long ſtanding, attended with loſs of appetite, waſting of fleſh, and weakneſs, it denotes a conſumption; and that the lungs are full of knotty, hard ſubſtances, called tubercles, which have often been diſcovered on diſſection.

The following ſigns denote when the cough proceeds from phlegm, and ſlimy matter, that ſtuff up the veſſels of the lungs.

The horſe's flanks have a ſudden quick motion; he breathes thick, but not with his noſtrils open, like a horſe in a fever, or that is broken-winded; his cough is ſometimes dry and huſky, ſometimes moiſt, before which he wheezes, rattles in the throat, and ſometimes throws out of his noſe and mouth great gobs of white phlegm, eſpecially after drinking, or when he begins or ends his exerciſe, which diſcharge commonly gives great relief. Some ſuch horſes wheeze and rattle to ſuch a degree, and are ſo thick winded, that they can ſcarce move on, till they have been out ſome time in the air; though then they will perform beyond expectation.

Theſe are properly aſthmatic caſes, and ought to be diſtinguiſhed in their ſymptoms from that purſiveneſs and thick windedneſs we ſee in ſome horſes, occaſioned by too full, or foul feeding, want of due exerciſe, or their being taken up from winter's graſs. But theſe two laſt caſes are eaſily cured by proper diet and exerciſe; the one by lowering his keeping, and the other by increaſing it.

The above aſtmatic caſe proves often very obſtinate; but, if it happens to a young horſe, and the cough is not of long ſtanding, it is greatly relieved, if not totally cured, by the following method.

If the horſe is full of fleſh, bleed him plentifully; if low in fleſh, more ſparingly; which may occaſionally be repeated, on very great oppreſſions, and difficulty of breathing, in proportionate quantities.

As mercurial medicines are found remarkably uſeful in theſe caſes, give a mercurial ball, with two drams of calomel, over night, and a common purge the next morning: or the following, which is much recommended by Mr. Gibſon:

Take gum-galbanum, ammoniacum, and aſſa-fœtida, of each two drams; fine aloes, one ounce; ſaffron, one dram; oil of anniſeeds, two drams; oil of amber, one dram; with honey enough to form into a ball.

They may be repeated at proper intervals, with the uſual cautions. In the intermediate days, and for ſome time after, one of the following balls may be given every morning:

Take cinnabar of antimony, finely levigated, ſix ounces; gum-ammoniacum, galbanum, and aſſa-fœtida, of each two ounces; garlic, four ounces; ſaffron, half an ounce: make into a paſte for balls, with a proper quantity of honey.

Theſe balls are extremely well calculated for this purpoſe: but if they are thought too expenſive, the cordial ball may be given, with an eight part of powdered ſquills and Barbadoes tar: or equal quantities of the above, and cordial ball may be beat up together; and where they can be afforded, balſam of Peru, balſam of ſulphur, and flower of Benjamin, would undoubtedly, added to the cordial ball, make it a more efficacious medicine, in caſes of this ſort, as thus:

Take of the pectoral or cordial ball, one pound; balſam of Peru, half an ounce; balſam of ſulphur aniſated, one ounce; flower of Benjamin, half an ounce: honey as much as is ſufficient to form them into a paſte: give the ſize of a pigeon's egg every morning.

Exerciſe in a free open air is very ſerviceable, and the diet ſhould be moderate. Horſes ſubject to any inward oppreſſions of the lungs, ſhould never be ſuffered to have a belly full; that is, they ſhould never be permitted ſo to diſtend their ſtomach with meat or water, as to preſs againſt the midriff; which of courſe would hinder reſpiration. Their hay ſhould even be abridged, given in ſmall quantities, and ſprinkled with water; and their uſual allowance, both of corn and water, ſhould be divided into ſeveral portions: by ſuch a regulation in diet, horſes may be ſo recovered as to do great ſervice; and in all diſorders of the lungs, it is what ſhould principally be attended to.

The following are the ſymptoms of a dry cough, or aſthma.

The horſe afflicted with this cough, eats heartily, hunts, and goes through his buſineſs with alacrity, appears well coated, and has all the ſigns of perfect health; yet he ſhall cough at particular times almoſt inceſſantly, without throwing up any thing, except that the violence of the cough will cauſe a little clear water to diſtil from his noſe. Though this cough is not periodical, yet ſome of theſe horſes cough moſt in a morning, after drinking.

This may properly be ſtiled a nervous aſthma in a horſe, as probably it chiefly affects the nerves in the membranous parts of the lungs and midriff; and is a caſe very doubtful at leaſt, if not incurable: but when the horſe is young, the following method may be ſucceſsful:

Take away firſt a moderate quantity of blood; then give him two drams of calomel, mixed up with an ounce of diapente, for two nights; and the next morning a purging ball. Keep him well cloathed and littered, and feed him with ſcalded bran and warm water.

Once in eight or ten days this purge may be repeated, with one mercurial ball only, given over night.

The following balls may then be taken, one every day, about the ſize of a pullet's egg, the horſe faſting two hours afterwards; and ſhould be continued two months, or longer, to be of real ſervice.

Take native cinnabar, or cinnabar of antimony, half a pound; gum-guaiacum, four ounces; myrrh, and gum-ammoniacum, of each two ounces; Venice ſoap, half a pound: the cinnabar muſt be finely levigated; as before obſerved, and the whole mixed up with honey, or oxymel ſquills.

The following alſo will be found a uſeful remedy in obſtinate dry coughs:

Take gum-ammoniacum, ſquills, and Venice ſoap of each four ounces, balſam of ſulphur, with anniſeeds, one ounce; beat up into a maſs, and give as the former.

Theſe mercurial and ponderous medicines are well adapted to open obſtructions in the lungs, and prevents thoſe little knots, or tubercles, which ſo frequently ulcerate, and lay the foundation of an incurable malady, or conſumption; but the common pectorals alone will

avail nothing in old ſtubborn coughs, their efficacy being loſt in the long tour they have to make, before they come to the lungs; and indeed, were it otherwiſe, without they had ſuch powerful openers joined with them, they would be of little conſequence; for where there are expectations from medicines, ſuch are chiefly to be relied on, which have a power of diſſolving and attenuating the viſcid humours, opening the ſmall obſtructed veſſels, and promoting all the natural ſecretions.

Before we conclude this article, it may be neceſſary to obſerve here, that ſome young horſes are ſubject to coughs on cutting their teeth, their eyes alſo are affected from the ſame cauſe. In theſe caſes always bleed, and if the cough is obſtinate, repeat it, and give warm maſhes; which, in general, are alone ſufficient to remove this complaint. But when the cough is an attendant on worms, as it often is in young horſes, you muſt give ſuch medicines as have a power to deſtroy thoſe animals: particularly mercurial phyſic, at proper intervals, and intermediately half an ounce of Æthiop's mineral, mixed up with the cordial; or pectoral balls may be given every day. *See* WORMS. *Bartlet's Farriery, page* 51.

But horſes are not the only animals ſubject to this diſorder: it is ſo common among ſheep, that one ſeldom paſſes near a flock without hearing it in ſeveral. They cure this diſorder in the Ardennes by throwing up their noſtrils with a ſyringe blanched almonds pounded in wine, for ſix or eight days ſucceſſively.

COUPLES, ewes and lambs.

COW, the female of the bull.

Cows are very ſerviceable to the huſbandman for work, and for the ſupply of the family and market. The beſt breed is reckoned that of Yorkſhire, Derbyſhire, Lancaſhire, Staffordſhire, &c. and a good hardy ſort for fatting on barren, or middling ſort of land, are your Angleſey's and Welſh. The hardieſt are the Scotch; but the beſt ſort of cows for the pail, only they are tender and require very good keeping, are the long-legged, ſhort-horned cow, of the Dutch breed, which is to be had in ſome places of Lincolnſhire, but moſtly in Kent; many of theſe cows will give two gallons of milk at a meal: but in furniſhing yourſelf with cattle, you ought to conſider the goodneſs of your land, and the uſe you deſign your cattle for, as whether for breed, milk, or work.

If for breed, the better your land is, the larger may your kine be; and the cheaper, the more will be your profit; only obſerve, that of what kind ſoever your breed is, that it be the beſt of the ſort, and let your bull be of the ſame country with your cow, for a mixed breed is not reckoned to be ſo good.

The cow ought to have a broad forehead, black eyes, large clean horns, her neck long and thin, a large deep belly, thick thighs, round legs, ſhort joints, a white large deep udder, having four teats, and her feet large. As for the ſize of your cows, as of all other cattle, it muſt be ſuited to the goodneſs of your land, though the largeſt commonly give the moſt milk: and whether you deſign them for breed, fattening, or the dairy, let them be ſuch as come off a worſe ground than your own, if poſſible. The beſt time to breed calves is from three years old to twelve. *See the article* CALVES.

For a fortnight or three weeks before a cow calves, put her into good graſs; or, if it be in winter, give her hay; and be ſure to keep her in the houſe the firſt day and night after ſhe has calved, and let a little of the cold be taken off the water which you give her: the next day, if well, and ſhe be well cleaned, turn her out about the middle of the day, and take her in two or three nights more, giving her water a little warmed every morning, before you turn her out. *Mortimer's Huſbandry, vol.* I. *p.* 225.

COW-LEASE, paſture, or meadow-ground, kept for feeding of cows.

COWHERD-MILK, implies milk received from the hands of the cowherd, a perſon whoſe office it is to attend upon, and look after, the herd of cows in places where they run in common.

COWL, a term uſed in ſome counties of England to ſignify a tub.

COW-PARSLEY, the name of a plant common in paſture grounds, and of which cows are ſaid to be very fond. This plant ſhould be rooted out of all paſtures, for it is one of the moſt early plants in ſhooting, ſo that by the beginning of April its leaves are two feet high. The ſeeds of this plant ſpread greatly over the ground, and as the roots are perennial, ſo they are often very troubleſome weeds to deſtroy.

COW-PARSNIP, *wild parſnip*, *meadow parſnip*, or *madrep*, the name of a weed that grows to near three feet high. The ſtalk is round, furrowed, and hollow. The leaves proceed from a large membrane or ſheath. They grow on long hairy ſtalks, and are divided and downy. The flowers grow in large umbels, are white, and conſiſt of five irregular petals: two oval, ſtreaked, compreſſed ſeeds, ſurrounded by a wing, ſucceed each flower.

COW-WHEAT, by ſome called *fox-tail*, is a pernicious weed in many countries. Its ſeed is ſomething like wheat, and according to Cluſius, ſpoils the meal with which it is ground, by giving it a dark colour, and a bitter taſte: though Mr. Ray ſays he could never perceive any diſagreeable reliſh in the bread with which it was mixed. Mr. Millar ſays it is a delicious food for cattle, particularly for fattening of oxen and cows, and that it may be worth while to cultivate it for that purpoſe.

Its ſeeds ſeldom grow the firſt year, unleſs they chance to be ſown, or ſow themſelves, in the autumn, ſoon after they are ripe.

CRADLE, a part often added to a ſcythe, the better to gather the corn, when low, into ſwarths, when it is mowed.

CRAGG, *cragge*, a name given in Suffolk to the remains of marine ſhells, of various kinds, and in which the greater part of the Britiſh cliffs abound.

This is a very excellent manure for cold, wet, or clay land; ſo that every farmer would do well to ſearch his grounds, in order to know whether he is, or is not, poſſeſſed of this treaſure, which will inſure him of very large crops of corn, though his lands were before worn out by continual labour.

CRAKE, a name given in the northern counties to the crow.

CRAKE-NEEDLE, the ſhepherd's needle; or rather the ſeed-veſſels of it.

CRANE's-BILL. *See* CROWFOOT, CRANE's-BILL.

CRAP, a name given in ſome parts of England to darnel; and in others to buck-wheat.

CRATCH, or *critch*, a rack.

CREAM, the unctuous, or oily part of milk.

CUBBITTING, a vice to which ſome horſes are ſubject; conſiſting in their catching hold of the manger,

ſucking

ſucking in of the air, and ſwallowing it down in gulps, till they are often ſo full that they are ready to burſt. Some do it only on their collar reins, and ſome on every poſt and gate they come at.

This vice is more common in London than any where elſe, and may either come upon horſes from very low feeding, whilſt they are young and have appetites, or perhaps, by ſtanding much at the crib while they are ſhedding their teeth; for then their mouths are hot, and their gums tender and itching, which may readily make them ſuck in the air to cool their mouths: but young horſes are the more apt to imbibe this ill habit, when they ſtand next thoſe that do it; for young horſes often follow others. Horſes addicted to this vice are but of ſmall value; they drop a great part of their food unchewed, which makes them almoſt always look lean and jaded, with a ſtaring coat, and conſequently few of them are able to endure much labour; beſides their being frequently ſubject to the gripes, and other diſorders, owing to their continual ſucking in the air. There is no method yet known, that has proved effectual in the cure of this vice. *Gibſon on Horſes, vol.* I. *p.* 40.

CRIBBLE, coarſe meal, or that but one degree better than bran.

CROFT, a ſmall field or incloſure. In the northern counties it is uſed as a ſmall cloſe or incloſure, one end of which contains the dwelling-houſe and kitchen-garden.

CRONES, old ewes.

CROP, the produce, or the quantity of corn, graſs, &c. growing on any parcel of land.

CROSS-TINING, a method of harrowing land, conſiſting in drawing the harrow up the interval it went down before, and down that which it was drawn up.

CROTCH, a hook.

CROW, an iron bar, with a claw at one end, uſed as a lever, and for making holes in the ground, &c.

CROW-FOOT, or CRANE'S BILL, the name of a perennial weed common in paſtures. The leaves are divided almoſt to the middle, uſually into ſeven parts. The ſtalk commonly divides into two branches; and each of theſe into two more. From the corner of each diviſion comes a flower-ſtalk, ſupporting two large blue flowers; conſiſting of five roundiſh, intire petals, ſucceeded by a long ſeed-veſſel, reſembling a crane's-bill. This bill-like ſeed veſſel is thick and rough; but not ſo long as in ſome other plants.

CROWS. *See the article* ROOKS.

CROWN-SCAB, a diſeaſe in horſes, conſiſting in an humour, that breaks out round the coronet; of a very ſharp and itching nature, and attended with ſcurfineſs. Sharp waters prepared with vitriol are generally uſed for the cure of this diſorder: but the ſafeſt way is firſt to mix equal parts of marſhmallow ointment and yellow baſilicon together, ſpreading the compoſition on tow, and laying it all round the coronet. A doſe or two of phyſic may be very proper, to carry off the humour. *Bartlet's Farriery, p.* 296.

CUCKOW-FLOWER. *See the article* LADIES SMOCK.

CUCKOW-LAMBS, a name given in Hertfordſhire to ſuch lambs as are yeaned in April or May, becauſe they fall in cuckow time. They are generally either the lambs of very young, or very old ſheep, and occaſioned by their taking ram very late in the ſeaſon. Theſe lambs are uſually of the ſmalleſt ſort, and therefore both ewe and lamb ſhould have the beſt of keeping, in order to fatten the lamb for the butcher; for ſuch diminutive lambs are improper to be kept for ſtore-ſheep. Beſides, as theſe lambs are yeaned later than ordinary, it is very likely they will meet with green meat ſufficient to fatten them apace, and come in ſeaſon to be ſold for the more money; as they are of the youngeſt ſort, and fatted late. *Ellis on Sheep, p.* 79.

CUCKOW-SPIT, a kind of frothy ſubſtance frequently found on plants, containing one or two inſects.

M. Poupart tells us, that as ſoon as the little creature comes out of its egg, it haſtens to ſome plant, which it touches with its fundament, and faſtens there a drop of white liquor full of air; it drops a ſecond near the firſt, then a third, and ſo on, till it covers itſelf all over with a ſcum, or froth; this froth defends it from the heat of the ſun, and alſo from the attacks of the ſpiders, which would otherwiſe devour it. Mr. Liſle is of opinion, that this froth is nothing more than the nightly dew which falls upon the fork or joint of the plant, and which the little inſect, with its proboſcis, as with a pair of bellows, works into froth.

CULMIFEROUS *Plants*, ſuch as have a ſmooth jointed ſtalk, and their ſeeds are contained in chaffy huſks.

CULTIVATION, the art of improving ſoils, and forwarding or meliorating the produce of the earth, by manual labour, manure, &c.

CULTIVATOR, a name given by foreign huſbandmen to inſtruments invented for ſtirring the earth, on the principles of the New Huſbandry. Theſe inſtruments are generally called in England horſe-hoes. We ſhall here give a deſcription of thoſe invented by Meſſrs. de Chateauvieux and de Villiers, and deſcribe thoſe invented in England under the article horſe-hoe. *See* HORSE-HOE.

Deſcription of M. de Chateauvieux's *ſingle* CULTIVATOR.

M. de Chateauvieux, having remarked the good effects of his plough in ſtirring the alleys between the rows of corn, rightly judged, that the inſtrument we are now going to deſcribe, which is much lighter and ſimple in its make, would anſwer the ſame end; or at leaſt that it might be uſed alternately with the plough, employing this laſt only when a greater quantity of earth is to be turned up towards the rows of corn: "for, ſays he, it is to be obſerved, that the cultivator hardly changes the ſituation of the earth, but divides and breaks it in the place it is in, ſo as to render it looſe and light, and fit for the roots of plants to penetrate with eaſe. This inſtrument, like a miner, works chiefly under ground, where it cuts the earth, divides its particles, raiſes it up, and lightens it. It has this farther advantage, that one horſe is ſufficient to draw it. The cultivator, Plate VII. is compoſed of a beam, AB. Fig. 1. the handles CD, and the ſhare EF, which is more particularly repreſented in Fig. 2, 3, 4, 5, and 6.

"The beam AB is three feet and a half, or four feet long. Its diameter ought not to exceed three inches at moſt; and, if it be ſquare, the edges ſhould be rounded off. It ſhould be pierced with mortiſes under the letters G, H, in order to let through the croſs ſtaves I, L; in the ſame manner as in the fore-carriage of the plough; and is fixed by the keys K, M, or the pins *a*, *b*. The

middle of the handles ſhould be exactly oppoſite to the beams; that is to ſay, the ſpace between them ſhould be equal on both ſides. Theſe handles ſhould be made ſlighter than thoſe of the plough before referred to, and they ſhould be fixed to the beam by a tenon in a mortiſe, riveted at N, and ſupported behind by the prop P.

"The end A of the ſhare, Fig. 3. and the two fins B, C, are made flat. The crooked handle ABC, Fig. 4, ſhould be triangular, and ſomewhat ſharp before, to anſwer the end of a coulter, as in Fig. 2, and 5.

"This ſhare is to be let into a grove cut in the under part of the beam, as repreſented in Fig. 7, and 8; and faſtened there by a ſingle ferrule, as in Fig. 9. If it ſhould cut too deep, that may be remedied by altering the poſition of the wheel, as in the plough, or by inſerting a very ſmall wedge *g*, Fig. 10, between the handle of the ſhare and the beam. If it does not cut deep enough, that wedge muſt be inſerted, as at *h*, Fig. 11. at the other end of the handle.

"When this inſtrument is uſed, the beam before deſcribed is to be ſubſtituted in the place of that of the plough, which is to be taken off. The two croſs ſtaves I, L, Fig. 1, of the fore carriage of the plough, are then run through the mortiſes G, H, of this beam, which is thereby fixed to that fore-carriage.

"This cultivator is very eaſily guided: the ploughman may hold it upright, or incline it to the right or left, juſt as the intended ploughing may require. The ſhare and its handle enter ſo deep into the earth, as to be quite buried in it, if a deep ploughing is intended to be given: and in that caſe the tail A of the beam touches the ground. Though the ſhare is but ſmall, it ſtirs the earth at-leaſt a foot round it: its point ſhould be of ſteel, and ſomewhat inclined towards the earth.

"The ſhare of this inſtrument, like that of the plough, may be brought as near as one pleaſes to the rows of corn, by placing the beam accordingly in the frame."

Deſcription of M. de Chateauvieux's *double* CULTIVATOR.

"This inſtrument, Plate VII. Fig. 12, 13, and 14, has two ſhares. It has a beam AB, and the ſhares CD, EF, Fig. 13, which being exactly like that of the ſingle cultivator, I have only to point out wherein theſe inſtruments differ. The beam of this ſhould be ten or twelve inches longer than that of the other. It has likewiſe two mortiſes more, under the letters G and H, to let through the croſs ſtaves EK, IL, which bear the handles MN, OP of the ſhares. The croſs ſtaves EK, IL, are riveted permanently to the beam: the handles MN, OP, are moveable upon the croſs ſtaves, to which they are faſtened by the keys R, S, Q, T; ſo that the ſhares may be ſet at a greater or leſs diſtance from each other, according as the quality or ſituation of the ground may require to allow.

"This inſtrument ſtirs the earth extremely well, and does a great deal of work in a little time. Each ſhare being about fifteen inches wide at AC, BD, Fig. 14, and the diſtance between them from A to B, Fig. 14, being about four inches, or, upon occaſion, ſix; and the earth being ſtirred about two inches on each ſide beyond the extent of the utmoſt fins of the ſhares; each cut of this cultivator ſtirs about two feet breadth of ground. This double cultivator requires two horſes, unleſs the ſoil be very light; in which caſe, I fancy one may do, though I have not yet tried it.

"If one had a mind to fix a coulter in the middle of the beam, juſt before the ſhares, I ſee no inconveniency that could ariſe from thence, provided it be a very light one.

"The way to uſe this cultivator is to faſten it to the fore-carriage of the plough, by running the two croſs ſtaves V, X, Fig. 13, through the beam A, B.

"I would particularly recommend, not to make the wood work of this cultivator too thick or heavy, and therefore by no means to exceed the dimenſions I have given: for the lighter theſe inſtruments are, the more eaſily they are managed both by men and cattle."

Deſcription of M. de Chateauvieux's CULTIVATOR, *with two Mould-boards.*

"If, ſays M. de Chateauvieux, I could have imagined, that my propoſing for the uſe of the New Huſbandry, ſome other inſtruments beſides the plough, properly called, could have been looked upon as either ſo expenſive or ſo troubleſome as to diſcourage people from practiſing that huſbandry; I ſhould not, by any means, have thought of communicating them to the public.

"But why ſhould not agriculture enjoy the ſame advantages as almoſt all great manufactories, in which every uſeful diſcovery and improvement, either to perfect the manufacture, or to fabricate it in leſs time and with leſs expence, is readily adopted?

"It is with a view to facilitate the various labours of cultivation, to execute them better, more ſpeedily, and with much leſs expence, that I have introduced the uſe of my new inſtruments in the culture of my own lands. If others think proper to do ſo too, they will enjoy the ſame advantages. I offer them, not as things abſolutely neceſſary, for the plough alone may ſuffice; but as things of which I have experienced the good effects during the years 1753 and 1754; and which, for that reaſon, I think it incumbent on me to recommend to thoſe who adopt the New Huſbandry.

"The cultivator with two mould-boards differs from the ſingle cultivator before deſcribed, only in the two mould-boards which I have added to it, one on each ſide, and which are repreſented in Plate VII. Fig. 15. A, C, E, H, is the mould-board on the left-hand ſide of the plough; and B, D, G, H, the mould-board on the right-hand ſide. The whole of this Fig. 15, repreſents an entire and a perſpective view of the ſhare and mould-boards.

"The mould-boards are made of plates of iron, either caſt or hammered, about the twelfth part of an inch thick; which is ſufficient to reſiſt the preſſure of the earth. Thicker plates than theſe would render the ſhare too heavy, and it would be much more difficult to give them their proper bent.

"The two mould-boards join to the handle at HL, and lap about an inch one over the other; or elſe they are faſtened together by rivets. They form, in that part, an angle E, H, F, of ſomewhat leſs than ninety-degrees, which is ſufficiently acute to ſerve inſtead of a coulter: though a coulter may alſo be uſed upon occaſion, by placing it a little more forward.

"From the lower part L of the handle, the mould-board ſhould paſs underneath the fin L, G, of the ſingle ſhare, and follow the direction of that fin, as at G; being let in beneath, about an inch and an half, accord-

ing

ing to the pointed line LG, and firmly riveted by three ſtrong rivets.

" The hind part of the mould-boards is fixed and ſupported by the ſtay F, to which they are ſtrongly riveted. This ſtay muſt have exactly the ſame bend as the mould-board.

" Behind the lower part of the handle is another ſtay, M, N, quite cloſe to it, and about two inches below the top of the mould-boards, to which it is riveted at both ends. This ſtay helps to keep them firm: but its chief uſe is to prevent their being raiſed up by the preſſure of the earth againſt their extremities A and B, which would throw their common angle H too forward, and miſplace the ſhare.

" The proper ſlope of the mould-boards cannot be ſo well deſcribed by words, as it may be conceived by the figure, which repreſents at F the convex inſide of the one, and at Q the concave outſide of the other. The diſtance to which the earth is turned over, when the cultivator opens it in order to make a large furrow, depends on the degree of this bending, and the ſpace between the two upper extremities of the mould-boards E, F.

" The hind-moſt part of the mould-boards is cut ſloping at C and D, almoſt in a ſegment of a circle. This ſhape helps to effect a greater diviſion of the earth.

" The plate of iron, before it is bent, ſhould be cut nearly in the ſhape of Fig. 16.

" The ſize of the mould-boards, as well as their proper bending, depends a little upon the quality of the land intended to be cultivated. I have found that, for light ſoils, they need not be bent quite ſo much: ſo that the diſtance from C to D, Fig. 15, may be twelve or thirteen, and even fifteen or ſixteen inches. This ſame cultivator may likewiſe be uſed in ſtiff lands.

" Nothing hinders making theſe mould-boards two or three inches longer, from B to G, and from E to H; or varying ſome of their proportions, as the huſbandman may think beſt.

" This ſhare with the mould-board, is fixed to a beam, as in the ſingle cultivator, Fig. 1, where it is faſtened to the fore-carriage, by the croſs ſtaves I, L.

" If this deſcription does not convey a ſufficiently clear idea of the ſhape and proportions of this cultivator, I will anſwer for its ſucceſs when uſed. I deſcribe it after one of the ſame kind, which I have made uſe of for two years paſt, with very great ſucceſs."

Directions for uſing the CULTIVATOR, *with two Mould-Boards, by M. de* Chateauvieux.

" This cultivator opens the main furrow in the middle of the alley, by turning the earth over on both ſides at the ſame time; and I have found by experience, that as much work is done by that means, by one turn of this inſtrument, as could be done by two, and frequently three turns of the common plough, and that without uſing a greater number of cattle. I muſt now prove this propoſition; though I am perſuaded that it will eaſily be allowed by whoever only caſts an eye upon Fig. 15, Plate VII. which repreſents the ſhare of this cultivator." *See the article* ALLEY.

Deſcription of a CULTIVATOR *invented by M. de* Villiers.

" This inſtrument is compoſed of a ſhare, Plate VII. Fig. 17, the two fins of which are eight inches, and a half aſunder at their extremities *a*, *b*. The ſocket *e*, which is between the two fins, projects ſome inches, and the hollow in it is three inches long, and one inch wide. It does not deſcend ſo low down as the fins, to prevent its touching the earth. The length of this ſhare, from the point *d*, to the extremity of the fins *a* or *b*, is from 12 to 13 inches. At the diſtance of five inches from the point *d*, is a hole *e*, into which is inſerted the crooked point *f*, of the iron ſafeguard, Fig. 18, which is uſed in ſome countries in order to faſten the ear to the ſhare of the plough. Upon the ſhare is placed a ſmall triangular ear *h*, Fig. 20, 21, and 22; ſomewhat concave at bottom, that the two ſmall ears may join exactly to the ſhare at about an inch diſtance from the edge of the fins. This ear is about two inches and a half high at *a*, Fig. 21, and is faſtened firmly to the ſhare by a double and angular ſafeguard, which covers its edge as far as *b*. It is fixed at one end by its point, which enters into the hole *e*, Fig. 17, in the ſhare, and by four ſmall pins faſtened to the ear. Fig. 18 and 19, repreſent this ſafeguard. The double ear is faſtened at its other extremity, by the ſheat or upright piece, *e*, *g*, Fig. 21, which paſſes through the ground-reſt of the hinder part of the ear, and beam, and by a piece of iron *c d* bent in a right angle. This piece of iron covers the fore-part of the ſheat, and reſts upon the tail of the ear, againſt which the beam preſſes it very tight, by means of a wedge *e*, driven into the ſheat. The piece *c d* may likewiſe ſerve to fix two mould-boards from *g* to *c*. It is nine inches high. *f* is another ſheat or upright piece, which joins the beam to the ground-reſt, to add to the ſtrength and ſolidity of the inſtrument, which is increaſed alſo by the lower part of the handles being fixed in the ground-reſt at *i*, and traverſed by the beam at *k*."

M. de Villiers, in a letter to M. Duhamel, gives the following account of his manner of uſing this cultivator.

" Finding it impoſſible to plough my alleys well when they were but three feet or three feet and a half wide, without greatly damaging the rows of corn bordering upon them; I reſolved to make them four feet wide, and took particular care to have the rows drilled very ſtrait: but even then I found only one way of ploughing them well, which is, to open the firſt furrow ſo near to the bed, that the next furrow within that may come within two or three inches of the neareſt row of plants in the bed; turning over the earth of theſe furrows towards the alley. After two or three ſuch turns of the plough, the ploughman will be ſure not to make any miſtake. It is of great importance to cut this firſt furrow, by which all the others are directed, quite parallel to the rows. The reſt of the work will then go on regularly, and without any of that confuſion which would be capable of giving many people a diſlike to the new huſbandry. My horſes were led by hand, till they were ſufficiently accuſtomed to this work: but that was neceſſary only for the firſt furrow, which they afterwards follow of their own accord, ſo that the reſt of the alley is ploughed with great eaſe.

" The earth of the ſecond furrow, which is cut very near to the rows, is turned over in the ſame direction as that of the firſt; that is to ſay, from the bed.

" The third furrow is ploughed the contrary way, and the earth is then turned over towards the rows, ſo

that the laſt furrow is filled up by this ploughing, and a conſiderable quantity of well divided earth is turned over to the rows, for the plants to extend their roots in in the ſpring.

"I then continue ploughing in the ſame direction, cutting the furrow that is turned over towards the rows as thick as poſſible, till the whole alley is ploughed almoſt cloſe to the oppoſite bed, when, by turning over one large furrow on that ſide, the ſmall one cut there at firſt is filled up. By this means, the ſpring hoeing is completely executed.

"I begin the ſecond ploughing on the ſide where I ended the firſt, turning the earth over that way, which is the contrary to what was done before: when I come to the other ſide of the alley, I leave there, as was left before on the ſide I now begin at, the breadth of a ſmall furrow, which I do not plough, but over which I turn the earth of my laſt furrow.

"I think this ſecond hoeing may be deferred, when the ground does not produce many weeds: and in this caſe I perform it with the cultivator, which I bring almoſt cloſe to the rows.

"After thus uſing, ſometimes the plough, and ſometimes the cultivator, according as the condition of the ground ſeems to require, I finiſh all my hoeings by putting two horſes to the cultivator, and drawing it once or twice through the middle of the alleys; becauſe it cuts four or five inches deeper than the plough."

M. de Villiers adds, that he could not always turn the earth over towards the rows, as M. Duhamel directs, becauſe the wheel of his plough, getting too deep in the middle furrow, altered the direction of the ſhare. To this M. Duhamel obſerves, that he himſelf met with the ſame difficulty, and found no other way of remedying it, but by opening a ſmall furrow near the rows, by the help of which he turned the earth over towards the alleys, and then filled up that furrow immediately; taking care at the ſame time to turn the mould over towards the roots of the plants, ſo as to earth them up as much poſſible. "I am glad, adds he, that I have had this opportunity of giving M. de Villiers's method, becauſe I think it a good one, and believe it will be of great ſervice to ſuch as may be inclined to practice the new huſbandry." *Duhamel's Cultures des Terres, tome* I.

CULTUR, or rather *Coulter*, the piece of iron that cuts the earth before the plough-ſhare. *See the article* PLOUGH.

CULTURE, the art of cultivating, improving, or meliorating the ſoil.

CULVER, a pigeon.

CURB, an iron chain faſtened to the upper part of the branches of the bridle, in a part called the eye, and running over the beard of the horſe.

CURB, is alſo the name of a diſeaſe in horſes, conſiſting in a ſwelling at the junctures of the bones on the hind part of the hock, forming a pretty large tumour over the back part of the hind leg, attended with ſtiffneſs, and ſometimes with pain and lameneſs.

A curb proceeds from hard riding, ſtrains, blows, or kicks. The cure at firſt is in general eaſily enough effected by bliſtering repeated two or three times, or even oftener. If it does not ſubmit to this treatment, but grows exceſſively hard, the quickeſt and ſureſt way is to fire with a thin iron, making a line down the middle from top to bottom, and drawing ſeveral lines in a penny form manner pretty deep; and then to apply a mild bliſtering plaſter or ointment over it. This method will entirely remove it. *Bartlet's Farriery, p.* 262.

CURRY-COMB, an iron inſtrument full of ſmall teeth, uſed for currying horſes.

CUSPATED *flowers*, thoſe whoſe petals or flower-leaves end in a point.

CUTTING-BOX, a machine for cutting fodder, as ſtraw, hay, haum, &c. into ſmall pieces, commonly called chaff, for the uſe of cattle.

We have given on Plate VI. Fig. 11. a cut taken from the Muſeum Ruſticum, Vol. VI. page 10, of an improved cutting-box. The improvement conſiſts in what the inventor calls a preſſer, which is a piece of wood as long as the box is wide, with three iron tongues in it, like thoſe of a hay-fork. Theſe tongues are put into the bundle of hay or ſtraw to be cut; and by means of a rope fixed thereto, and extending under the box, the preſſer is forced down by the left foot of the cutter, and conſequently the bundle kept tight. By this means the chaff is cut with great eaſe; and after every cut, the operator riſes his left-foot, puſhes his ſheaf or bundle forward with his left-hand, then preſſes it down again with his foot, and takes another cut. In this manner he continues working, till the whole bundle is reduced to chaff.

This deſcription will be very eaſily underſtood by inſpecting the figure above referred to, where A is the preſſer, B a large knot at the end of the rope, which faſtens it to the preſſer, C the rope, D F, the ſlit in which the rope moves, as the cutter puſhes the bundle forward. E the loop in which the cutter puts his left-foot. F the box to contain the hay, ſtraw, &c. The knife is not delineated in this figure, as the manner of placing it is ſufficiently known.

A correſpondent of the editors of the Muſeum Ruſticum tells us, that he never gives his horſes any pure corn, but always makes uſe of his cutting-box, in which his ſervants cut his horſe-meat, which conſiſts of unthraſhed oats, tares, peaſe, or beans. They cut off the heads where the corn lies, and take beſides a cut or two of the ſtraw to mix with it. This he gives to his horſes inſtead of corn: it being a very nouriſhing food, and of which they are very fond. Nor is there any danger of their being ſurfeited with it, which they often are with pure corn; many of their diſorders ariſing from their being over-fed.

"I cannot, continues he, enough commend the uſe of a cutting-box, though I am perſuaded the ploughmen will endeavour to prepoſſeſs their maſters againſt it, becauſe the cutting of the horſe-meat is pretty tough work, and they do not, in general, love to do more than they can help.

"When oats, beans, peaſe, or tares, are intended to be thus cut for horſe-meat, it is beſt to mow them before they are quite ripe, as by that means fewer of them will be loſt by ſhaling, and the ſtraw, or ſtalks, will be of a better quality, and more nouriſhing for the cattle.

"Care muſt, however, be taken that the crop be well dried before it is houſed, leſt it heat in the mow, and take damage, if not ſet the barn, or ſtack, on fire." *Muſeum Ruſticum, vol.* I. *p.* 258.

CYDER, or *Cider*, a liquor made from the juice of apples, expreſſed and fermented.

A Herefordſhire planter has given us the following method of making cyder in that county, which has been ſo long famous for this liquor.

"The worſe, ſays he, the apple is for the table, the better it is, in general, eſteemed for cyder, ſuch as grow all over this county, and are, in a manner, wild, harſh, and crabbed to the taſte. Theſe go under various names, as the redſtreak, the white and green muſts, the gennet-moyl, the ſtocking apple, the ſummer and winter fillets, &c. &c. of all which I prefer the firſt, provided it is a good ſort, which is not always the caſe, particularly in ſome parts of Worceſter and Glouceſterſhire, where they grow in great plenty.

"I have long laid down from experience, the beſt miſtreſs, that, firſt, the more red an apple is in its rind, the fitter it is for cyder; that is to ſay, if it is at all fit; for I have ſeen an apple of very deep red, by ſome called ſopſy-wine, quaſi ſopped in wine, which was worth nothing in this intention.

"Secondly, That the paler the rind, the worſe the juice.

"Thirdly, I have found it a maxim in general true, that a ſweet apple with a tough rind will always yield a good vinous liquor.

"Fourthly, The more yellow the fleſh of the fruit, the better and finer coloured will the cyder be.

"Theſe few maxims, not too ſcrupulouſly adhered to, have been of great ſervice to me in life; for though I have a high opinion of them, I do not abſolutely rely on them. There is no rule ſo general, but an exception may be made to it; but a man of reflection, with a few well-founded rules, will ſeldom be at a loſs how to act in this, or in any other caſe.

"I ſeldom ſuffer my apples to be gathered till they begin of themſelves to drop from the trees: nature then tells me they have, for the moſt part, acquired a proper degree of maturity.

"Great care is taken in the gathering of them, for fear they ſhould be bruiſed in the operation; and this I have always found a very neceſſary precaution.

"As they are gathered I have them ſorted, according to the ſeveral degrees of ripeneſs they are of, making, in general, three ſorts, which a little experience eaſily teaches to ſeparate properly, the difference being apparent enough at firſt ſight.

"As faſt as they are gathered and ſorted, they are carried under a ſhed prepared for the purpoſe, and laid in large heaps to meliorate: this practice I cannot enough recommend, as being of great ſervice to the liquor, improving its quality, and making it keep, without compariſon, better; and all this is cauſed by a little ſweating in the heap.

"Yet, good as this practice may be, ſome avaricious planters cannot be induced to adopt it, becauſe, ſay they, the apples freſh from the tree will yield better; as, of theſe laſt, about twenty buſhels will give a hogſhead of cyder; whereas, of the other apples, which have been heaped, it will take about twenty-five to make the ſame quantity.

"I ſuffer my apples to lie in the heap a longer or a ſhorter time, according to the nature of them, ſuch as are harſh and ſolid requiring to lie longer, by ſeveral days, than thoſe that are mellow and pulpy; and the degree of maturity the apples had attained before they were heaped, makes alſo ſome difference in this reſpect.

"I have already obſerved, that I divide my fruit into three ſeveral ſorts, according to the ſtate of its maturity: I have now to add, that from theſe three ſortings I have no leſs than ſix ſeveral kinds of cyder, each different from the other in taſte, flavour, and quality.

"As faſt as the fruit is ground (I need not, I think, mention that I uſed the ripeſt firſt) the pulp is put into a large vat near the preſs: at the bottom of the vat is a tap, through which a conſiderable quantity of the prime vinous juice will run without any preſſing, induced by its own weight only: this produces my beſt cyder; and I always tun it up by itſelf: the pulp is afterwards preſſed in the uſual way. The ſame proceſs is uſed in all the three ſortings of apples; by which means I get, as I ſaid before, ſix ſorts of cyder.

"The firſt runnings from the vat I immediately put into the veſſels in which it is to remain; only, if it happens, by any accident, to be too foul, I ſtrain it firſt. I allow here but a ſmall vent-hole, and when it has done working, I fill the veſſel with ſome of the ſame liquor reſerved for that purpoſe: I afterwards, by degrees, cloſe the vent till it is finally and well ſtopped.

"As to the juice, which undergoes the action of the preſs, I put this, as ſoon as it runs off, into veſſels, where I ſuffer it to remain about thirty hours, according to the ſeaſon, till the *faeces* are precipitated, or fallen to the bottom; after which I draw it off, and tun it up in the veſſels in which it is to remain, with the precautions, however, above-mentioned, when I treated of the firſt runnings.

"The kind of veſſels I uſe, and which I think by far beſt, are upright hogſheads, broader at the upper head than at the bottom; and I often, after my cyder has done fermenting, caſt two or three handfulls of wheat-bran into each veſſel, which ſerves to thicken the head or cream of the liquor, and makes it keep better.

"I am very careful with reſpect to the veſſels into which I put my cyder, always avoiding new ones, if poſſible, as they give the liquor a twang, or bad taſte, and hurt its colour; my uſual way is, to ſeaſon all my new caſks, that I poſſibly can, with ſmall beer, which I uſe in common in my family, though I live in a cyder country; and if I have not an opportunity of doing this, I ſcald them with water, in which a conſidetable quantity of apple-pulp has been boiled.

"If a veſſel is not ſweet, it may eaſily be cured, unleſs very bad indeed, by putting ſome unſlacked lime into it, adding ſome cold water, ſtopping it cloſe, and rolling it about till the noiſe within is no longer heard.

"I have often found it of great uſe towards enlivening the liquor, to ſlice about a dozen ſweet apples into a hogſhead: I am alſo inclined to think it makes it keep better.

"The beſt cyder I ever had was a few years ago, when I put in each hogſhead about three quarts of good wheat firſt boiled and hulled, ſo as to have, in ſome meaſure, the appearance of boiled rice.

"When I am obliged to put any cyder into a caſk I ſuſpect, and afterwards diſcover it has given the liquor a bad taſte, I cauſe ſome muſtard ſeed to be ground in a quern with ſome cyder: this mixture, being put into the hogſhead, is often of great ſervice, and reſtores it to its original good taſte.

"Cyder, when it is tunned, is very apt to loſe that fine mild ſpirit which renders it ſo pleaſant and briſk a liquor;

liquor; therefore great caution ſhould be uſed with reſpect to the vent. The wild, furious, and ungovernable ſpirit ſhould be ſuffered to eſcape; which may eaſily be effected by leaving a ſmall vent open for a few days; after which the barrel muſt be cloſe ſtopped, for if it gets any vent, the liquor will ſtand a great chance of being entirely ſpoilt; on the contrary, if well bunged, though it may be dead and flat at firſt, it will ſoon recover itſelf, maturate, and be fit for drinking. This particular part of the management of cyder is critical, and depends greatly on the temperature of the air, ſo that it is impoſſible to give any abſolute directions about it, as ſomething muſt ſtill be left to be learned by experience, and governed by diſcretion.

"I muſt give one particular piece of advice to ſuch as intend making cyder, which is, that they diligently watch the alterations in it upon every change of weather, as a ſmall neglect, at ſuch times, is often fatal to many hogſheads, and the danger is much greater in ſummer than in winter. There is ſcarcely any diſeaſe incident to this liquor, but what may eaſily be cured by a timely application: if it is only a little inclined to tartneſs, wheat, managed as above-mentioned, will cure it; and the ſame thing is alſo very good to preſerve it, when it is drawn out of one caſk into another: the quantity when the liquor is tart is about half a peck to a hogſhead; I have ſometimes even put a quart more.

"This ſimple remedy will, I ſay, often cure the tartneſs I mentioned; but ſometimes, when it is very thick and ſouriſh, it may be neceſſary to raiſe a new fermentation, to purge off the impurities, and make them ſubſide: this may be ſoon done by bruiſing the fleſh of a few apples to a pulp with ſome of the liquor, and putting the whole into the bung-hole of the veſſel; this will raiſe a ferment, and cure the cyder: when that is over, it will be proper to draw it off into another caſk; and it will alſo be a very uſeful precaution, to put into the laſt mentioned veſſel about a quarter of a peck of wheat, prepared as I have already directed: this will give it new life and ſpirits, and make it keep better, and drink much pleaſanter.

"I have ſometimes alſo uſed another method to cure tart cyder; but it has not always ſucceeded with me; why, I cannot ſay, as ſome people, who live not many miles from me, have great dependence on it. Something may depend on their ſoil differing from mine, though this may, to ſome of your readers, ſeem to have a very remote analogy to the caſe in hand. The remedy is, to break half a dozen new-laid eggs, and beat them up, ſhells and all, till they are brought to a frothy oil: this is put into the bung-hole of a hogſhead, and, as I am credibly informed, ſometimes proves a very efficacious remedy: it has ſucceeded with me, but not ſo often as to induce me to depend much upon it; I mention it, however, as it may prove of more efficacy with others than it has with me.

"An induſtrious planter will, by the conſtancy of his obſervations and remarks, always have it in his power to cure his own liquor by receipts of his own diſcovering; and for this purpoſe I would recommend, that he be continually making experiments, and that whatever trials he makes, be in various modes and proportions; for the remedy that may be of no ſervice in one form, may poſſibly be very efficacious when altered with judgment, which judgment can only be acquired by experience and obſervation.

"It is to be noticed, that, if the cyder is acid, and at the ſame time clear, it is in a very dangerous ſtate, being but rarely recovered: therefore, in general, when this is the caſe, the cure is ſcarcely worth attempting.

"I have often uſed wheat for the recovery of my cyder in other forms, ſometimes putting about half a peck, unground, into a hogſhead for it to feed on; at other times I have made dough of coarſe meal with the bran in it, adding ſome leaven, uſing no ſalt, and putting warm cyder, or white wine, inſtead of water, in the mixture: this dough I make into lumps about as large as my fiſt, and thruſt them into the bung-hole of the hogſhead, the quantity being about half a peck of the meal to a hogſhead.

"Many mix different kinds of ſpice with their liquor, particularly ginger, which they think of great ſervice; but I never uſe it now, ſeldom having found any great effect reſulting from it, and being of opinion that it renders the cyder more unwholeſome than it can poſſibly in its own nature be; for, though the ginger may not make any very ſenſible alteration in the immediate taſte of the liquor, it muſt, I think, ſtrongly impregnate it with its fiery particles, and thereby greatly irritate the maſs of blood, and inflame the lungs of ſuch as drink any quantities of liquor wherein it has been infuſed: others, however, may differ in opinion from me: I know, indeed, many that do ſo; therefore I only declare my opinion." *Muſeum Ruſticum, vol.* II. *p.* 37.

It is of great importance in the making of cyder, that the fruit be thoroughly ripe. The juices of unripe apples retain their harſh, ſour taſte, in ſpite of all endeavours, and never acquire that racy, mellow flavour, which the ſun only can beſtow. Sweating together in a heap will, indeed, give them an artificial ripeneſs; but this is not equivalent for that which they receive from nature, which, though it receives ſome aſſiſtance from the induſtry of man, can never be completely imitated by art.

It ſhould, therefore, be the firſt care of every one concerned in the making of cyder, to let his apples hang upon the tree till they arrive at full maturity. But no certain time can be aſſigned for this: it varies with the nature of the fruit, and the circumſtances of the ſeaſon. Different apples have different times of ripening; and the ſame, according to the weather, change their times conſiderably from one year to another: but ſigns there always are ſufficient to direct the huſbandman. The brownneſs of the kernels, their rattling in the apple, the fragrant ſmell of the fruit itſelf, and its ſpontaneouſly falling from the tree in calm weather, are certain indications, which, in all kinds, may be depended on. It is, however, an uſeful caution in this, as in every other caſe, to err on the right-ſide, and to let the apples hang too long, rather than too little. Summer fruit, indeed, will ſuffer by this method, grow pulpy, dry, and mealy, and afford little or no juice. In every other caſe the rule is good, and in the beſt fruits, moſt. The harſher kinds can hardly hang too long, for they daily mend upon the tree: their juices mellow, throw off their crude and watery parts, and conſequently, as the crude juices leſſen in quantity, the apples improve proportionably in quality. They may hang upon the tree as long as the weather can be expected to continue

tinue open: but ſevere froſt ſhould be moſt carefully avoided, becauſe it deſtroys the texture of the fruit ſo much, that even cold water, the only remedy in ſuch caſes, will not reſtore it to its former ſtate: for as all fluids enlarge their dimenſions when frozen, the containing veſſels of all ſucculent ſubſtances muſt be thereby burſt, and this has upon the fruit an effect ſimilar to a bruiſe, or any other cauſe that deſtroys the veſſels, whereby the extravaſated liquors ſoon putrify. From this cauſe it is that the ſtrongeſt foreſt trees are often rent aſunder in very ſevere froſts.

When your apples are fit for gathering, it is eſſential to chooſe dry weather for that purpoſe: for water is a bad ingredient in all vinous liquors, and your fruit ſhould therefore be guarded from it with peculiar care. The wet which adheres to the apples after rain or dew, or even the ſmaller quantity of moiſture which they might contract by falling or lying upon graſs, is ſufficient to impoveriſh your cyder in a ſenſible degree. Gather your fruit therefore in the drieſt day, and in the drieſt part of it, when the dew is thoroughly exhaled, and, of choice, gather it by hand. This method may, perhaps, be troubleſome and difficult in plantations of great extent, and where the trees are very tall: but wherever it can be uſed it is of great advantage, and certainly quits coſt. You then can chooſe your apples, and leave upon the tree thoſe which are not of a ſufficient ripeneſs: you ſave your fruit from bruiſes, and your trees from the damage they frequently receive by violent unſkilful ſhaking.

The gathering by hand is ſo eſſential, eſpecially for winter fruit, which is to be ſweated for a conſiderable time, that it ſhould not by any means be diſpenſed with; becauſe, as every wounded part of an apple will rot in the ſweating, a very great loſs muſt be occaſioned, both in the quantity of the fruit, and in the longer time taken up in wiping and rubbing off every ſpeck of rottenneſs upon each ſingle apple. This laſt labour is indiſpenſible; becauſe, otherwiſe, the putrid taint would ever remain in the liquor. Thoſe who plead the want of time, where a great quantity of fruit is to be preſſed, may be anſwered, that it would be more to their advantage to have only half the quantity of good cyder, than the whole of indifferent; and the gathering may certainly be expeditiouſly performed by means of ſtep-ladders. The apples may be put into baſkets, as they are gathered, and thereby be preſerved free from hurt, and the tree will not be injured as the ſupport of the ladders here recommended is independant of the tree. However, for thoſe who will follow the contrary practice, the beſt method is, to cover the ground under the trees with a ſufficient thickneſs of ſtraw to ſave the apples in their fall, and to lay blankets upon the ſtraw; then, with an eaſy motion, to ſhake the boughs ſucceſſively, removing, at every ſhaking, the apples already fallen, that they may not be bruiſed by the next. By theſe means all your apples are kept dry, and, for the moſt part, free from bruiſes; and with a little additional care you may alſo, in this method, ſeparate the fruits according to their ripeneſs: for if you proceed regularly from bough to bough, and give each a gentle ſwing, the ripeſt will fall firſt, and the unripe remain upon the tree till more violent motion brings them down.

Windfalls, as they are generally termed, bruiſed apples, and thoſe which have not been well ripened, ſhould not by any means be mixed with the choice fruit; for if they are, it would be in vain to expect good cyder: the quantity of it may indeed be large, but it will always be proportionably bad. This fruit need not, however, be thrown away, excepting only that part of it where the bruiſe appears black and mouldy; for a very little of this would communicate an offenſive taſte to the whole liquor. The reſt will make inferior kinds of cyder; and if care be taken that the windfalls do not lie too long upon the ground, and if keeping cyder be not expected from bruiſed apples, they will anſwer tolerably well: nay, Mr. Newburg tells us, in a letter ſubjoined to Mr. Evelyn's Pomona, that a neighbour of his aſſured him he had made a quantity of very good cyder with windfalls, which he ripened by ſweating them for about a month, that they were beaten off the tree earlier than the ſeaſon when nature would otherwiſe have compleated their maturity; but that all the neighbours of this perſon, who preſſed their untimely fruit as ſoon as it fell, had a crude, auſtere, indigeſted liquor, not worth the name of cyder.

The ſweating of the apples has, however, been made a matter of ſome diſpute. The writer of the 24th letter in the Dublin Society's Weekly Obſervations diſapproves of it for choice ripe fruit, and inſtances his having been informed of ſome curious gentlemen who carried their thoroughly ripe apples directly from the tree to the grinding mill, without any previous ſweating, and obtained from them ſome of the beſt cyder they ever taſted. As to the winter fruits, he thinks it probable that the neceſſity of ſweating them might be removed, by leaving them upon the trees ſomewhat longer than is neceſſary to ripen them; "no reaſon," (ſays he, without having perhaps ſufficiently attended to the benefit which fruit receives from being diſcharged of its watery parts,) "hitherto appearing to make us think that this fermentation by ſweating ſerves any other uſe than to increaſe the degree of maturity which the fruit had acquired upon the tree.---It is indeed poſſible," continues he, "that it may anſwer farther purpoſes, and diſpoſe the fruit to an eaſier emiſſion of its juices: and as our reaſonings upon nature frequently loſe their way, where experience does not guide them, it is from trials only that we can form a judgment to be depended on: recourſe muſt therefore be had to actual experiments, which in this caſe are eaſy, and will certainly quit coſt: for which ever way the queſtion be determined, ſomething muſt be found very well worth the knowing. Should ſweating anſwer ſome purpoſe not to be attained upon the tree, it will, when once diſcovered, aſcertain the nature, the uſe, and the degree of ſweating: or ſhould nothing of this kind appear, it will correct a practice, which, if it does no good, muſt certainly do miſchief: ſince it is evident to common ſenſe, that if maturity be all that is wanting, it is more perfectly and more naturally attained upon the tree." However, till this is determined by experience, it will be right to continue the practice of ſweating every apple: for as to windfalls, and other hard and unripe fruit, it is out of diſpute, that as they are deprived of natural maturity, they muſt be aſſiſted by art.

Upon the whole, there ſeems in this caſe, one rule which may be followed for all fruits; namely, to preſs their juice for fermenting at the time when the fruit itſelf is in the greateſt perfection for eating. Experience teaches

us,

us, that there are few apples which do not require time for their being mellowed, before they attain to their higheſt flavour. The golden pippin, for example, is in its greateſt perfection when kept till October; and in favourable years it will retain its flavour and juicineſs even till Chriſtmas, or longer. The nonpareil does not attain its chief excellence till near Chriſtmas, and after that it continues in perfection ſeveral weeks. It is therefore during the time theſe apples continue in perfection, that they are fitteſt to be preſſed for cyder; and the ſame will doubtleſs hold good of the other ſorts, none of which ſhould be preſſed before they have attained their higheſt flavour, nor after they have begun to loſe it. A principal advantage accruing from the ſweating of apples is, that the fruit is thereby deprived of the watery parts of its juice, which would only weaken the liquor; while its pulp yields a greater quantity of the enriched juice after it has been mellowed.

The material points to be obſerved in the ſweating of apples are, that the fruits be ſeparated according to their different degrees of ripeneſs, and that the floor on which they are laid be as dry as poſſible. The more ſtrictly the former of theſe cautions is obſerved, the better it will be; and the more the fruit in every heap is alike in its maturity, the ſooner the ſweating will be over, and the leſs damage will accrue to the ripeſt and beſt apples in the heap. However, if care be taken not to mix any that are very ripe with others that are very green, the injury will not be great: but if this ſhould be neglected, as it too frequently is, either the ripe apples will rot, or the green ones will remain unmellowed; and in either of theſe caſes, the cyder will be conſiderably leſſened in its value. Boarded floors will beſt anſwer the intention of the ſecond caution, becauſe they are drieſt: earthen floors, however, if covered ſome inches deep with wheat, rye, or oat ſtraw, will do tolerably well. It is likewiſe eſſential, for the better preſervation of the apples, that they do not touch the walls or ſides of the ſtore-room in which they are laid to ſweat. To heap them up in the orchard, or any where elſe upon the graſs, or on an uncovered floor where the rains and dews have free acceſs to them, is a ſure way to make the cyder weak and watery, and frequently muſty and ill-taſted.

Sweating being then undeniably neceſſary, at leaſt for unripe, hard, and winter fruit, the huſbandman, who makes a conſiderable quantity of cyder, will find a great conveniency in having near his orchard a building, of which his mill and preſs ſhould occupy the lower floor, and his apples be ſweated in that above, from whence they may be conveyed into the mill by a proper trunk. The duration of the time of ſweating is beſt determined by the ſmell of the fruit; that is, whenever it emits a full ſcent of the apples, they are fit for the preſs. Different kinds require different lengths of time, viz. from eight or ten days, to ſix weeks. The harſher the apple is, the more time it wants.

Apples that have laid any time in heaps, are generally covered with a clammy moiſture, proceeding from their ſweating. This ſhould be well wiped off; for it is a watery juice, which would impoveriſh the cyder; and at the ſame time every bruiſed and rotten part of the apple ſhould be carefully cut out, and thrown away, and it ſhould be cleared of its ſtalk; becauſe the former would give a putrid taſte, and the latter too much roughneſs, to the cyder.

The common practice is to carry immediately the apples from the heap where they have been ſweated, to the mill, and then to grind them; but if we attend to the length of time during which they will remain in a ſucculent ſtate after having been ſweated, carefully wiped dry, and properly laid up in a place of preſervation; we ſhall find, that, if theſe directions are duly obſerved, the fruit will continue in a perfectly ſound ſtate, and fit to be made into cyder, till it may be convenient for the huſbandman to preſs it: but before he does this, or rather before he ſweats his apples, he ſhould take care to ſort them, or at leaſt all the moſt valuable kinds, and particularly the ſtire, under-leaf, fox-whelp, and golden pippin, which hitherto have not been found to do ſo well in mixtures, as each of them does by itſelf.

The juice of the apples is obtained either by pounding the fruit in a trough, or grinding it in a mill. The former of theſe is leaſt approved, becauſe it is ſo tedious as to ſuit only ſmall quantities, and the work is performed by it unequally, and with waſte; much of the liquor being daſhed out of the trough by the beating, and ſome of the apples being hardly broken, when others are reduced to a perfect pomice.

There are ſeveral engines uſed for grinding the apples; but one in particular, reſembling a tanner's mill, is uſed in many parts of England. It conſiſts of a circular trough in which apples are bruiſed by a large flat ſtone moved round upon its edge. This engine we have repreſented on Plate VI. Fig. 8, where M is the ſtone ſet upon its edge; N, the ſpring-tree bar, or that to which the horſe is faſtened; P, Q, R, the circular trough in which the ſtone moves; T, L, V, compartments, or diviſions for different ſorts of apples.

When the apples are ground, ſome carry them directly to the preſs; but others empty them out of the trough into tubs, or large, wide, ſhallow vats. This work is done with moſt eaſe by broad wooden ſhovels: which ſhould alſo be uſed to turn the pomice in the vats five or ſix times a day, to prevent any fermentation; the whole of this operation being chiefly intended to give the pomice a red colour, which afterwards heightens that of the cyder, and brings it to a deep, fine amber. This buſineſs is over in two days.

From theſe vats the pomice is carried directly to the preſſes, of which there are ſeveral kinds: we have given figures of two kinds on Plate VI. where Fig. 9. is the ſmall cyder preſs, by which the juice is preſſed out of the pomice by means of a ſtone, or block of heavy wood, cut in the form of the fruſtrum of a cone, and moveable about the center. The pomice is ſpread upon the bed of the preſs, where a conical preſſer is turned round by means of a lever inſerted into its baſis, by which means the juice is forced out, and conveyed by notches cut in the bed to the veſſel, by means of a ſpout, and repreſented in the figure.

Fig. 10, is a large cyder-preſs, where A B is the baſe with its ſupporters. C, C, the cheeks, which are upright beams, whoſe lower extremities are ſunk in the earth, where they are firmly fixed by croſs-bars and maſonry. They are connected at the top by two beams, the lowermoſt of which contains the nut, or female ſcrew. D, is the ſcrew with its wheel; below which is the bearer, or large piece of timber on which the force of the ſcrew is exerted, in order to ſink the beams croſſing the planks that cover the pomice or cheeſe, as it is then called. G, G, are

are the planks on which the pomice is diſpoſed in hair bags, in order to be ſqueezed: theſe planks are cut in notches to conduct the liquor to a veſſel properly placed to receive it. The bed of this preſs is ſupported on a maſſive work of maſonry. It is the wheel which forces down the ſcrew and bearer upon the pomice laid in hair bags upon the bed of the preſs. This is done by turning the wheel H round; for by that motion the cord is wound round its axis, and by that means the wheel fixed on the bottom of the ſcrew is turned round, and the bearer together, with the croſs planks under it, are forced down upon the pomice, laid in bags upon the bed.

Theſe bags hold about two or three buſhels, or as much as the mill can grind at once: and theſe are heaped over each other till the preſs is full. The larger preſſes will hold from eight to fifteen bags, which yield, from one to two hundred gallons of liquor, according to the largeneſs of the cheeſe. To perform the work neatly, it is neceſſary to have two ſets of theſe bags; for they clog and fur in preſſing, and, conſequently, become unfit for uſe till they have been waſhed and dried; ſo that while this is doing, either the preſs muſt ſtand ſtill, or another ſet be ready to employ it.

Some, inſtead of hair-bags, lay long ſtraw under the pomice, the ends of which they turn up over it; then cover the pomice entirely with freſh clean ſtraw, upon which they ſpread another layer of pomice, and ſo on, alternately, till the preſs is full. Either of the above methods will do: but thoſe who are deſirous of doing the work in the neateſt and beſt manner, generally uſe the bags.

It is uſual to diſpoſe of all the liquor preſſed out of the cheeſes, the ſame way, and without diſtinction: but if the analogy holds, as it ſurely does, between cyder and other vinous liquors, this muſt be a conſiderable error. Experience has ſufficiently ſhewn, that in making wines, there is a very great difference between the firſt yieldings of the grapes, and the juices which are afterwards extracted by hard preſſings; and this difference is always in favour of the former; ſo that, if the ſame be true of cyder, the richeſt, and choiceſt kinds are loſt, by an imprudent mixture of the whole.

It is an opinion generally received, and the writer of the letters in the Dublin Society's weekly obſervations, already mentioned, has adopted it; namely, that ſummer fruit do not make good cyder. "Summer fruit, or ſweet apples, ſays he, afford only a weak, pert, windy juice, agreeable enough to the palate from its livelineſs and tartneſs, but in a great degree unwholſome. It has no body, and therefore will not keep, and ſcarcely deſerves the name of cyder." But Sir Paul Neile, whoſe reaſoning we ſhall give in his own words, judged very differently.

"I aſſert, ſays he, that the beſt apples will make the pleaſanteſt, which in my opinion is the beſt cyder; and I account thoſe the beſt apples, whoſe juice is the pleaſanteſt at the time when firſt preſſed, before fermentation. I ſhall need, beſides the experience of the laſt ten years, only to ſay, that it is an undeniable thing in all wines, that the pleaſanteſt grapes make the richeſt and pleaſanteſt wines, and that cyder is really but the wine of apples, and not only made by the ſame way of compreſſion, but, left to itſelf, hath the ſame way of fermentation, and therefore muſt be liable to the ſame meaſures in the choice of the materials.

"This truth was not formerly owned, by reaſon that in Herefordſhire, and thoſe countries where they abound with pippins and hard apples of all ſorts, they make cyder of both kinds, and uſed them alike; that is, that as ſoon as they had ground and preſſed the apples and ſtrained the liquor, they put it into their veſſels, and there let it lie till it had worked, and afterwards was ſettled again and fined; as not thinking it wholeſome to drink till it had thus, as they call it, purged itſelf; and this was the frequent cuſtom of moſt men in the more ſouthern and weſtern parts of England alſo. Now, when cyder was thus managed, it is no wonder that when they came to broach it, they for the moſt part found their pippin cyder not ſo pleaſant as their moyle or red-ſtreak cyder; but to them it ſeemed a wonder, becauſe they did not know the reaſon of it, which I ſhall next explain: for till they knew the reaſon of this effect, they had no cauſe but to think it was the nature of the ſeveral apples that produced it; and conſequently to prefer the hard apple cyder, and to uſe the other apples, which were good to eat raw, for the table, for which the hard apples were totally improper.

"To ſhew that, in Herefordſhire, they know not what was the true cauſe why their pippin-cyder was not, as they uſed it, ſo good as the cyder made of hard apples, I ſay, that for all liquors which are vinous, the cauſe that makes them ſometimes harder or leſs pleaſant to the taſte, than they were at the firſt preſſing, is the too much fermenting. If wine or cyder by any accidental cauſe do ferment twice, it will be harder than if it had fermented but once; and if it ferment thrice, it is harder and worſe than if it had fermented but twice; and ſo onward, the oftener it ferments, and the longer it ferments, it ſtill grows the harder.

"According to the old method of making and putting up the cyder, they took little care to put up only the clear part of the liquor into their veſſels or caſks. Now pippins being a ſofter fruit, are in the mill bruiſed into ſmaller particles, than the harder ſorts of apples; and conſequently more of thoſe ſmall parts paſs the ſtrainer in the pippin cyder, than in the cyder of hard apples. This cauſeth a ſtronger fermentation, and, according to my former principle, a greater loſs of the native ſweetneſs, than in the hard apple cyder; and not only ſo, but the lee of the hard apple cyder being compounded of greater particles than the lee of the pippin cyder, every individual particle is in itſelf of a greater weight than the particles of the lee of the pippin cyder, and conſequently leſs apt to riſe upon ſmall motions. When the fermentation of the hard apple cyder is once over, a ſecond fermentation ſeldom happens, unleſs the veſſels be ſtirred: but in pippin cyder it is otherwiſe; for if the groſs lee be ſtill remaining with the cyder, it need not the motion of the veſſel to cauſe a new fermentation; but every motion of the air, by a change of weather, will cauſe a new fermentation, and conſequently make it work till it hath deſtroyed itſelf by loſing its native ſweetneſs. This alone hath been the cauſe why commonly when they broach their pippin cyder, they find it ſo unpleaſant.

"What firſt gave me the hint of this, is that in divers parts they make three ſorts of wine out of one and the ſame grapes; that is, they firſt take the juice of the grapes without any more preſſing than what comes from their own weight, and the bruiſing they

receive when put into the vat; which cauſeth the ripeſt of theſe grapes to break, and the juice, without any preſſing at all, makes the pleaſanteſt and moſt delicate wine. The ſecond ſort they preſs a little, which makes a wine neither ſo pleaſant as the firſt, nor ſo harſh as the laſt, which is made by the utmoſt preſſing of the very ſkins of the grapes, and is by much more harſh than either of the other two. Now I preſume the cauſe of this, at leaſt in part, to be, that in the firſt ſort of wine, which hath little of the ſubſtance, beſides the very juice of the grape, there is little lee, and conſequently little fermentation; and becauſe it doth not work long, it loſes but little of its original ſweetneſs. The ſecond ſort, being a little more preſſed, hath ſomewhat more of the ſubſtance of the grape added to the juice, and therefore, having in it more of that part which cauſes fermentation, ferments more ſtrongly, and is therefore, when it hath done working, leſs pleaſant than the firſt ſort, which worked leſs. For the ſame reaſon the third ſort, being moſt of all preſſed, hath moſt of the ſubſtance of the grape mingled with the liquor, and worketh the longeſt: but at the end of the working, when it has ſettled and is clear, it is much more harſh than either of the two firſt ſorts. The thought of this made me firſt apprehend, that the ſubſtance of the apple, mingled with the juice, was the cauſe of fermentation, which is really nothing elſe but an endeavour of the liquor to free itſelf from theſe heterogeneous parts which are mixed with it: and when there is the greateſt proportion of thoſe diſſimilar parts mingled with the liquor, the endeavour of nature muſt be the ſtronger, and take up the more time to perfect the ſeparation, which, when finiſhed, leaves all the liquor clear, and the groſs parts, called the lee, ſettled to the bottom of the veſſel. Nor did this apprehenſion deceive me: for when I began to ſeparate a conſiderable part of the lee from the cyder before it had fermented, I found it to retain a very great part of its original ſweetneſs, more than it would have done if the lee had not been taken away before the fermentation; and this not once, but conſtantly for ſeven years.

"The method which I uſed was this: when the cyder was firſt ſtrained, I put it into a great vat, and there let it ſtand twenty-four hours at leaſt, but ſometimes more, if the apples were more ripe than ordinary: then, at a tap before prepared in the veſſel, three or four inches from the bottom, I drew it into pails, and from thence filled the hogſhead, or leſſer veſſel, leaving the greateſt part of the lee behind. During this time that the cyder ſtood in the vat, I kept it as cloſe covered with hair-cloths, or ſacks, as I could; that ſo too much of the ſpirits might not evaporate.

"Now poſſibly I might be aſked why I did not, ſince I kept it ſo cloſe in the vat, put it at firſt in the veſſel: to which I anſwer, that had I put it at firſt into the veſſel, it would poſſibly, eſpecially if the weather had chanced to prove wet and warm, have begun to ferment before that time had been expired; and then there would have been no poſſibility to ſeparate any part of the groſs lee, before the fermentation had been wholly finiſhed; which keeping it only covered with theſe cloths was not in danger: for, though I kept it warm in ſome degree, yet ſome of the ſpirits had ſtill liberty to evaporate; which had it been in the hogſhead with the bung only open, they would not ſo freely have done; but in the firſt twenty-four hours it would have begun to ferment, and ſo my deſign had been fully loſt: for thoſe ſpirits, if they had been too ſtrongly reverberated into the liquor, would have cauſed a fermentation before I could have taken away any part of the groſs lee. The great myſtery of the whole lies in this; to let ſo many of the ſpirits evaporate, that the liquor ſhall not ferment before the groſs lee be taken away; and yet to keep ſpirits enough to cauſe a fermentation when you would have it: for if you put it up as ſoon as it is ſtrained, and do not let ſome of the ſpirits evaporate, but ſuffer the groſs lee to be ſeparated by its own weight only, without fermentation, it will ferment too much, and loſe its ſweetneſs; whilſt on the other hand, if none be left, it will not ferment at all, and then the cyder will be dead, flat, and ſour."

Experience taught Sir Paul, that it was neceſſary to delay the fermentation till late, or till the cold weather had come in, as he informs us, when he ſays, "It is neceſſary that the apples have a little time to ſweat in the houſe before the cyder is made; but not too much: for if they be not full ripe before they are gathered, and not ſuffered to lie a while in the heap, the cyder will not be ſo pleaſant; and if they be too ripe when they are gathered, or lie too long in the heap, it will be very difficult to ſeparate the cyder from the groſs lee before the fermentation begins: and in that caſe it will work ſo long, that when it fines, the cyder will be hard: for when the apples are too mellow, they will break into ſo ſmall particles, that it will be long before the lee ſettles by its own weight only; and then the fermentation may begin before it be ſeparated, and ſo deſtroy your intention of taking away the groſs lee. And if the apples be not mellow enough, the cyder will not be ſo pleaſant as it ought to be."

To the cauſe above aſſigned by Sir Paul Neile for the liquor's fermenting too much, another may be added; namely, that as the ſummer fruits are fermented earlier than the hard apples, the warmth of the weather hurries the fermentation on too faſt, and by this means renders the liquor much leſs palatable: or it may even hurry it beyond the vinous ſtate, till the acetous fermentatoin begins. The ſweetneſs of the ſummer fruits make them likewiſe more liable to ferment too much; whereas, the ſour roughneſs of hard apples retards that operation, and makes a longer time neceſſary to perfect the vinous fermentation. Theſe cauſes render it neceſſary that great care be taken in preparing the juice as directed by Sir Paul, and that there be a cellar in which the heat is ſuited to carry on as ſlow a fermentation as poſſible. If the maker of the cyder is not provided with ſuch a cellar, the juice of the apples may be buried in cold ſpring water, as before mentioned, and be kept there till the temperature of the weather becomes fit for its being fermented.

"What has been ſaid of the time for making the pippin cyder, may, adds Sir Paul Neile, with due allowances, for the nature of the apples, ſerve for all other ſummer fruit; as the Kentiſh-Codlin, marrigold, gilly-flowers, ſummer-pearmains, ſummer-pippins, Holland-pippins, golden-pippins, and even winter-pearmains. For though they muſt not be made at the ſame time of the year, yet they muſt be made at the time when each reſpective fruit is in the condition before directed for the pippin. Nay, even in the making of that cyder, you are not tied preciſely to that particular time, but, as the condition

dition of the year hath been, you may make your cyder one, two, three, or four weeks later."

When the preſſing of the apples is finiſhed, the moſt careful makers of cyder ſtrain their liquor through a hair ſieve, to ſeparate from it the coarſeſt dregs; which is a practice every way adviſable. It muſt then be leſt to itſelf, till it has undergone the neceſſary fermentation, and depoſited its groſſer lees. To this purpoſe ſome put it immediately into hogſheads, others into large tubs or vats, and the moſt curious into a veſſel intended for that very uſe, wide at top, and growing narrower all the way down to the bottom, near which is a tap to draw off the liquor. This veſſel is fixed upon a ſtand, or ſtilling, and frequently contains from five to twenty hogſheads. In theſe veſſels the heavier lees ſubſide, and the lighter form at top a cruſt, which by its ſinking afterwards, gives timely notice that the ferment is gone off, and that the liquor is fit for racking. Some gentlemen, who ſpare no pains to make their cyder as fine as poſſible, think that the excellence of the liquor depends greatly on catching the very inſtant when this cruſt breaks; and in order to be ſure of it, they ſet a perſon to watch and give immediate notice of the crack or noiſe which the cruſt makes in breaking. They hold this to be the critical time for racking off the liquor, and maintain, that ſo much of its ſpirit is evaporated very ſpeedily after, as to render the cyder irrecoverably vapid. This, therefore, ſhould be carefully attended to; and upon the firſt appearance of the cruſt's falling, the cyder, which is then become tolerably fine, ſhould be drawn off the groſſer lees, and tunned into the hogſheads. The uſual time taken up in this primary fermentation is from thirty-ſix to forty-eight hours; more or leſs, according to the weather. Some affirm that they have had good cyder by tunning it directly from the preſs, without any other caution than leaving room for the liquor to ferment in the hogſhead, where it remains from firſt to laſt: but this method is liable to many hazards, and ſucceſsful, where it has been ſo, only in favourable ſeaſons. The groſs lees are apt to riſe on every conſiderable change of weather, and when they do, they ſet the cyder on the fret, which, ſhould it do no worſe, certainly robs it of its ſpirit, and, when over, leaves it flat and vapid. Beſides, repeated experiments have proved, that ſourneſs in all fermented liquors begins ever at the lees, and therefore the more of them is left among the cyder, the more readily it will turn eager.

Here I muſt obſerve, that a moſt important precaution is too often overlooked by many of thoſe who make cyder of winter fruits; for that a ſufficient warmth of the air is as eſſential to ferment the rough juices of hard apples, as it is dangerous to ſuffer the heat to be too great in the fermenting of cyder made of ſummer fruits. If the weather is very cold when the hard apples are preſſed, the help of fires ſhould be recurred to; or if that has been neglected, or could not be conveniently uſed, it will be right to carry the cyder to a place warmed conſiderably by the ſun for a ſhort time, in the ſummer, and there to place it out of the immediate reach of the rays of the ſun. The bung of the caſk muſt be looſened, becauſe there will ariſe a degree of fermentation, which will attenuate any viſcidity not overcome by the firſt fermentation. Great care muſt be taken that this fermentation be not carried beyond the nice point of correcting the rough raw taſte of the fruit: for if it goes farther, the liquor will either become vapid, or turn to vinegar. As ſoon as the deſired point is obtained, the liquor ſhould be racked off, eſpecially if much feculence has ſunk to the bottom, and it ſhould then be carried down into the vault, where it may be preſerved long in perfection.

The choice of proper veſſels to keep the cyder in after it has fermented is very material; no liquor being ſo apt as this to take the taſte or tang of the caſk. New veſſels, though the wood be ever ſo well ſeaſoned, generally give a diſagreeable reliſh to all liquors, and will do ſo remarkably to cyder, unleſs due caution be uſed before-hand. Frequent ſcalding with hot water, into which ſome handfuls of ſalt have been firſt thrown, or with water in which ſome of the pomice has been boiled, and waſhing afterwards with cyder, are the uſual remedies againſt this evil, and ſeldom fail of removing it effectually. Of old caſks, beer veſſels are the worſt: they always ſpoil cyder; as, in return, cyder caſks infallibly ſpoil beer. Canary and brandy caſks do well, and all wine veſſels tolerably; for, provided the tartar adhering to their ſides be carefully ſcraped off, and they well ſcalded, there is no danger in uſing them. The beſt way of ſcalding them, is to boil a parcel of dried wormwood in water, and with that and a bruſh of the ſame plant to rub and ſcour their inſides. This will correct the acid of the tartar; and ſo will likewiſe all vegetable aſhes uſed in the ſame manner. Thoſe who adviſe fumigating the caſks with brimſtone, confidently affirm that the cyder becomes ſtronger, and keeps better, when the veſſels have been thus prepared, and for this reaſon they tun immediately after the operation, and before the ſmoak evaporates. To enable ſuch as may chooſe to examine, by fair trials, how far this is true in fact, I ſhall here add the neateſt method of performance. Melt a pennyworth of brimſtone, and dip in it a piece of new cloth, or of canvaſs, till all the brimſtone is imbibed, and the cloth or canvaſs looks like a piece of ſtarcloth: then roll it cloſe, tie it, and with a wire ſuſpend it at the bung, three parts in four within the veſſel; light it, and let it burn till it is ready to fall into the caſk, then take it out, and tun without delay. Some add a little powdered cinnamon, cloves, pepper or other ſpice to the brimſtone for fumigating; but I ſee no great reaſon for their ſo doing.

The beſt ſhaped veſſels for keeping cyder in are, as adviſed by captain Sylas Taylor, in a letter ſubjoined to Mr. Evelyn's Pomona, and by Mr. Worlidge, thoſe of which the barrel-boards are ſtrait, the veſſel broader at one end than the other, and ſtanding on the leſſer end, with the bung-hole in the top. The advantage of this form is, that in the drawing of the cyder, though but ſlowly, the ſkin or cream contracted by its fermentation (as is the caſe of all ſtrong liquors) deſcends, and covers the liquor by means of the tapering of the veſſel, and thereby preſerves to the laſt the ſpirits of the cyder, which would otherwiſe evaporate and waſte. A little wheaten-bran caſt in after the fermentation, thickens this coat or cream of the liquor, and thereby conduces much to its preſervation.

We come now to a point of great importance, and hitherto of as great uncertainty, which has raiſed among the curious a controverſy of long ſtanding, and not likely to be brought to a ſpeedy deciſion, without a courſe of regular experiments. Some maintain, that continued

fermentation and frequent racking certainly ſpoil the cyder; whilſt others aſſert, that it can never be good without them. Some rack once, ſome twice, and others whenever the liquor frets. Some look upon the lees as the food and nouriſhment of cyder: others, as a cauſe at hand, upon every change of weather, to ſet it on the fret, and turn it ſour. Every man has a ſyſtem of his own, and a peculiar practice conſequent thereon; and ſo great is the variety of methods, that nothing certain can be drawn from them but this one general concluſion, that we are ſtill at gueſs work, and muſt be obliged to future trials for any rules that can be thoroughly depended on. I ſhall therefore here relate the ſeveral ways now in uſe, and then give my own general opinion of this matter; but I ſtrongly recommend the making of accurate experiments on each.

One method is, to leave the cyder in the vats ſome days longer than was before adviſed, and till it fines in a great meaſure: then to tun it into hogſheads, where it is to remain without any farther racking. Thoſe who recommend this practice ſay, that their cyder is thereby rendered the ſtronger and mellower: and thoſe who object to it reply, that lying on the groſſer lees, which cannot all be fallen in the vats, it muſt be apt to fret, turn foul, and, in unſettled weather, eager.

A ſecond and more common method is, a fortnight after tunning, to rack into other hogſheads. There the cyder undergoes a ſecond gentle fermentation, and while this laſts the bung muſt be left open; afterwards, when the fermentation leſſens, covered only with a wet cloth, or a tile; and when it is quite over, ſtopped down cloſe with well tempered clay, kept moiſt, to prevent its cracking, by ſtrewing over it a handful of bay-ſalt.

To this ſecond racking others add a third in March or April, when the lees have thoroughly ſubſided. This again is followed by a little fermentation; and for that reaſon chiefly it is objected to by thoſe who think every fermentation hurtful which is not ſtrictly neceſſary.

Others, on the contrary, and particularly thoſe of Devonſhire, where the ſtrongeſt cyders are made, look upon thorough fermentation as the great ſecret to have their cyder fine, light, and free from dregs, and accordingly they not only approve of the above laſt mentioned method, but proceed much farther, as follows:

At firſt tunning they do not fill their hogſheads to the bung, but leave an empty ſpace to receive a pailful of freſh cyder from the preſs: this renews or increaſes the fermentation, and ſets the whole on working with ſome violence. The froth which riſes at the bung is carefully ſkimmed off, and the waſte of liquor thus occaſioned is conſtantly repleniſhed with unfermented cyder. By theſe means the whole is kept from the fret for a conſiderable time: for it is not uncommon to have cyder thus managed working for a fortnight. A month after this operation, and the ſtopping of the veſſels, the cyder is racked, and, generally ſpeaking, in two months more a ſecond time: and if it frets, which however is ſaid ſeldom to happen in this method, it is racked off a third and a fourth time.

To make a proper choice among the ſeveral above recited methods, they ſhould be tried together, with the ſame fruit, of equal ripeneſs; the cyders ſhould be kept to the ſame age, and their different qualities ſhould be attentively obſerved. Juſt information cannot be obtained in any other way: for the want of accuracy and exactneſs will render the experiment fruitleſs and inſignificant. Every one will tell you, that his method affords good cyder: but this general expreſſion gives no determinate idea, and forwards knowledge very little. Would gentlemen be at the trouble to keep notes, and minute down all the differences obſervable in the ſame cyders under different managements, it might ſoon be known what method gives the ſtrongeſt, which the neateſt, the rougheſt, melloweſt, or lighteſt cyders: and every one might then purſue, as his taſte or intereſt ſhould direct, that which would anſwer beſt: but till ſomething of this kind be done, only very ſlow and inconſiderable improvements can be expected.

In the mean time I muſt obſerve, in general, that whenever the lees of cyder are in ſuch quantity as that the liquor cannot preſerve them from a tendency to putrefaction, as muſt be the caſe with the firſt, and generally the ſecond lees, it is certainly adviſable to rack off the liquor; and that, if the cyder is kept in a place not ſubject to the various changes of the weather, the little fermentations raiſed by racking cannot be attended with any great danger; nor will the frettings return. But as to the frequently repeated fermentations which are ſaid to be, of choice, the practice of the makers of cyder in Devonſhire, they ſurely are by no means adviſable.

The few points which experience has hitherto determined in regard to the making of cyder are, that weak cyder cannot bear above one or two rackings without too great a loſs of ſpirits; that ſtrong cyder made of winter apples will ſtand ſeveral rackings, and thereby grow mellower, and be the ſooner fit for drinking; that the more the liquor is fermented, the rougher it will grow; that fermentation is no other way ſo well promoted, as by putting into the hogſhead from time to time ſome of the liquor freſh drawn from the preſs: and laſtly, that to have a rich, racy, palatable cyder, a little inclining to the ſweet, great care muſt be taken to prevent all future fermentation after the liquor is once become fine. If it ſhould be foul, iſinglaſs will help to fine it, by precipitating the flying lee.

In general, the cyder that is longeſt in fining is the ſtrongeſt and moſt laſting, if it has been made of thoroughly ripe fruit: but, as was before obſerved in the article of wines, all liquors will be much longer in clearing in mild moiſt weather, than in cold dry weather or froſt.

When the bung-hole of the veſſel is cloſed up, a ſmall vent-hole ſhould be left open, or but looſely ſtopped with a peg, for ſeveral days, till the wild ſpirit of the liquor be ſpent; for otherwiſe it will break the caſk, or find ſome other vent, which, though but ſmall, will always abide open, and prove the ruin of the cyder. Many have ſpoiled their cyder by this only neglect, and never apprehended the cauſe thereof. After this wild ſpirit is ſpent, the vent-hole, as well as the bung, ſhould be ſtopped quite cloſe; and then the cyder, though ſeemingly flattiſh at firſt, will ſoon improve, and become briſk and pleaſant.

Deadneſs or flatneſs in cyder, if occaſioned by a too free admiſſion of air into the veſſel, for want of right ſtopping, is remedied by grinding a ſmall parcel of apples, and putting them into the caſk, which ſhould then be ſtopped up cloſe: but care muſt alſo be taken to open the vent ſometimes, or the veſſel will be in danger of burſting. The liquor thus managed muſt likewiſe be drawn off in a few days, either into bottles, or into another caſk, leſt the

murk ſhould corrupt the whole maſs; to prevent which, ſome put in only the juice of the newly preſſed apples. The ſame may be done to flat bottled cyder, by adding about a ſpoonful or two of new muſt to each bottle of the dead liquor, and ſtopping it again. Cyder that is dead or flat will often revive again of itſelf, if cloſely ſtopped, upon the revolution of the year, and the approach of ſummer: but cyder which has acquired a deadneſs or flatneſs by being kept in a beer veſſel, cannot be revived again.

Thick cyder may be rendered clear and good by a ſecond fermentation, or, ſometimes, by only throwing into it two or three quite mellow apples. But cyder in which the acetous fermentation has taken place, can never be reſtored. If it be only a little ſouriſh, or drawn off in another veſſel, about a gallon of wheat (blanched is beſt) to a hogſhead of cyder, and ſo in proportion for any other quantity, will both amend and preſerve it: or if it is ſo ſour that the wheat does not anſwer that purpoſe, it may be corrected by egg ſhells, powdered alabaſter, &c.

Cyder which has contracted any ill flavour or taſte from the veſſel, or from any other cauſe, will be helped by the addition of a little muſtard ſeed ground with ſome of the cyder.

Ginger accelerates the maturation of cyder, gives it more briſk ſpirits, helps fermentation, promotes its duration, and corrects its windineſs.

When the juice is too thin or weak, it is common and very adviſable practice to give by art that ſtrength which nature had not beſtowed. To this end, raiſins of the ſun, or the lees of rich wines, are uſed with good ſucceſs; as is alſo ſugar. Writers on this ſubject give various directions for the uſe of this ingredient: but it would be needleſs to repeat them here, as it is of very little importance in what manner it be done, the giving a body to the liquor being the only thing wanting, and this a proper quantity of ſugar will effect, in whatever ſhape it is uſed. When the deſign is to colour the cyder, the ſugar is boiled till it becomes brown, and then put into the caſk.

CYTISUS, the name of a plant much cultivated by the old Romans for the food of cattle, and called by ſome ſhrub-trefoil, and by others ſhrub-lucern.

It riſes to the height of five, ſix, or even more feet, with a ſhrubby ſtalk, covered with a greyiſh bark, and divided into many branches, covered with a hoary down while they are young, and garniſhed at each joint with trifoliate leaves ſtanding upon foot ſtalks about an inch in length. There are two or three of theſe at each joint, ſo that the branches are cloſely covered with them. The lobes are ſmall, ſpear-ſhaped, and hoary on their underſide; and theſe leaves remain all the year. The flowers, which are of a bright yellow, blow on foot-ſtalks which ariſe from the ſides of the branches, each foot-ſtalk ſuſtaining four or five flowers; and theſe are ſucceeded by compreſſed moon-ſhaped pods, each containing three or four kidney-ſhaped ſeeds.

The cytiſus may be raiſed either from its ſeed ſown about the middle of October, or in the beginning of April; or if greater ſpeed be deſired, from cutting ſlips, or layers, planted in the ſpring or autumn, ſo as to leave a ſpace of four feet between each plant. Such are the directions of Columella, who adds, that if the ground be well dunged for this planting, and well hoed up round the plants, which ſhould be watered during the firſt fortnight, if rain does not fall, plentiful crops may be obtained from this excellent vegetable, equally fit for horſes, oxen, cows, ſheep, hogs, goats, and poultry. It is alſo ſingularly profitable for bees, whoſe honey it increaſes prodigiouſly. It has the ſame effect upon the milk of cows, beſides greatly improving its quality. In the kingdom of Naples the goats feed upon it, and great quantities of excellent cheeſe are made from their milk. In the iſlands of the Archipelago, the Turks make handles for their ſabres of the wood of this ſhrub, which, when full grown, is as hard as ebony, and of a fine yellow colour. It will bear cutting as often as its ſhoots are about fifteen or eighteen inches long, which may be ſeveral times in the year; for it ſhoots and flowers during eight months in the countries where it grows well, and continues green during the whole winter, if the ſeaſon be at all favourable. Its ſeeds begin to ripen towards the end of Auguſt, and continue to do ſo until the cold ſtops them. It will be fit for cutting at the end of three years at fartheſt, and ſhould be carefully kept clear of weeds, and hoed up between each cutting. If given as green fodder, which it affords during eight months of the year, about fifteen pounds weight of it are ſufficient for the daily food of a horſe, twenty pounds for an ox, and ſo in proportion for other cattle, according to their ſize and ſtrength. When made into hay, it ſhould be given more ſparingly, becauſe it is then more nouriſhing. In this ſtate it ſhould be ſteeped in water, before it is given to cattle, and then be mixed with chaff or ſtraw. The time of cutting it for hay, is when the greater part of its ſeeds begin to grow large; and the manner of making this hay is, to let the ſwarths lie ſome hours in the ſun, till they are faded, and then to dry them thoroughly in the ſhade. *Columella De Ruſtica, Lib.* V. *cap.* 12.

Mr. Miller allows the cytiſus every quality that can recommend it for the feeding of cattle in the countries where it grows naturally, ſuch as the iſlands of the Archipelago, Sicily, and the warmeſt parts of Italy, but is perſuaded that it will not thrive in England, ſo as to be of any real advantage for that purpoſe here; becauſe it cannot bear ſuch hard froſts as we ſometimes have; or if it does not bear them ſo far as not to be abſolutely killed, it will be ſo much damaged thereby, as not to be able to recover its verdure before the middle or latter end of May; nor even then to put forth ſhoots that will bear cutting more than once in a ſummer; beſides, their being ſo woody, if ſuffered to grow to any conſiderable length, as to render that cutting very troubleſome, and of little ſervice by way of fodder. He therefore thinks, upon the whole, that it can never anſwer the trouble and expence of cultivation in this country, where we have many other preferable plants; but that, in hot, dry, rocky countries, of which we have now ſeveral in our colonies, where few other vegetables will thrive, this may be cultivated to great advantage; for it will live there many years, and proſper very well.

D.

DAB-CHICK, a chick newly hatched.

DAG, dew hanging upon the graſs.

DAIRY, the occupation, or art of making various kinds of food from milk, particularly butter and cheeſe. It alſo ſignifies the place where theſe operations are performed.

The following account of managing a dairy was written by a gentleman who has for a conſiderable number of years employed himſelf in that buſineſs, and acquired by his induſtry a plentiful fortune.

He begins with recommending the cultivation of ſaintfoin to every perſon concerned in a dairy, as it is obſerved to increaſe the milk of cows, both in quantity and quality, above any artificial paſture yet known, and therefore he adviſes the farmer to keep his cows upon it, and form a five years dairy.

"An acre of the worſt land, continues he, will, when improved by this graſs, maintain four cows very well from the firſt of April to the end of November, and afford beſides a ſufficient ſtore of hay, to make the greater part of their ſubſiſtance the four winter months following. You muſt buy then about four hundred milch-cows, but take care you chuſe them with judgment. I have bought your largeſt ſort of runts from Wales, for leſs than fifty ſhillings a cow, with a good calf by her ſide, which I always diſpoſed of as ſoon as I could. You will obſerve, that I make too good an uſe of the milk to afford the calf his ſhare of it: I generally keep theſe cows above twelve months, and then, ſelling them, ſometimes for four pounds a-piece, I ſtock myſelf with ſuch that are new milched. I obſerve this rule every year, and the trouble is ſufficiently rewarded by the advantage it brings me; for beſides the profit I make by ſelling dearer than I buy, I avoid the inconvenience of having any thing to do with bulls, and the conſequences; ſo that I always preſerve my cows in their full milk, and find it no uncommon thing for one of theſe milch-cows to be milked twice a day, and afford a gallon and a half at a meal. Four hundred of theſe cows will coſt a thouſand pounds; and you will find, that, coming from a poor paſture to a rich, they will proſper and increaſe both in milk and ſize. In eight convenient places about your hundred acres let there be built eight thatched ſheds; a little riſing in the middle to carry off the water; the height may be ten feet, and the breadth thirty; each of theſe ſheds ſhould be a hundred and twenty-five feet long, and, under the higheſt part, directly in the middle, you muſt raiſe a ſlight partition, lathed and plaiſtered, which ſerves to ſupport the ridge of the roof, while the two ſides are ſuſtained by ſquare wooden poſts, about eight feet high, and placed at proper diſtances.

"On either ſide of the partition wall let there be fixed a kind of a rack, like thoſe in ſtables, which is to run the whole length of the ſhed, and muſt be placed as high as a cow can reach her fodder from. The ſhed muſt next be divided into ſtalls, like thoſe for ſtone-horſes, and each ſtall will be above five feet broad; the length of theſe ſtalls muſt be exactly fitted to that of a cow, that a croſs bar, being placed at the outward end, may keep the beaſt from running backwards: thus every ſhed will hold fifty cows, five and twenty on each ſide of the partition: to every one of theſe ſheds you muſt appoint a man, whoſe buſineſs it will be to clear the place, and carry off the dung; as alſo to mow the ſaintfoin every day, and give it to the cows in the rack before-mentioned: this man beginning at one end of his proportion of ground, and going gradually on to the other, the firſt place will always be fit to mow again by that time he has gone through his whole diviſion. Your cows are thus fed at diſcretion, with neither too much nor too little; they are not peſtered with the ſcorching heats, nor troubled with the ſtinging fly, which, in open paſtures, often makes them whiſk about, and trample down more graſs than they eat. At each end of every ſhed you muſt build a ſlight room of brick, thirty feet ſquare, and ten feet high, which is to be divided, the croſs-way of the ſhed, into two partitions, each fifteen feet broad, and thirty feet long; that which joins the cow-houſe muſt be paved with tiles, and is to ſerve for a dairy; the other muſt be floored and windowed, and is to be a lodging-room for the dairy-maids. Every ſhed will require five maids, that is, to every ten cows one dairy-maid; fewer might ſerve, but it is better to exceed, than fall ſhort, in this particular. Thus each dairy will have two or three maids belonging to it, whoſe lodging will be the room adjoining, and whoſe care is to extend to the ſhed on both ſides the partition, to the five and twenty cows which are the neareſt to their ſtation. All along both ſides of the partition, at about a foot above the ground, let there be fixed, cloſe to the wall, a ſtrong pipe of lead, a little leſs than an inch diameter; both which pipes, being ſomewhat raiſed exactly in the middle of the ſhed, muſt have a gentle and almoſt an inviſible deſcent from that riſing to the dairies, through the wall of which their nether ends are to be brought, and there wrought into one another, that whatever deſcends through them, into either of the dairies, may have iſſue but at one mouth. This mouth of the pipes muſt be made very ſmall, and neatly fitted into the hollow end of a ſtrong wooden axle-tree; which, whilſt it is turning ſwiftly round the mouth of the pipe, may by no means ſtrain it by the motion, but receive, into its own hollow,

hollow, the milk which deſcends through the leaden pipes, without ſpilling any, and paſſes ſo far through a wheel, or veſſel like a barrel, only much larger in its circumference. The axle-tree, which this veſſel is to turn upon, is bored very full of round holes, through which it delivers the milk into the veſſel, as faſt as it receives it from the pipe.

"The veſſel muſt be capable of containing, at leaſt, three times the quantity of milk, which it is deſigned to receive; and there muſt be ſix wings or thin pieces of wood, glued on edge-ways to the wooden axle-tree, whoſe length and breadth muſt be ſo contrived, as to leave a free ſpace of ſix inches at either end of the axle-tree, and a foot between their edges length-ways, and the ſmooth inſide of the veſſel; in the moſt convenient part of which muſt be contrived a door, to open and ſhut down upon occaſion, as cloſely as if there was none. This door will perform its work very neatly, if you line the inſide and edges with ſome kind of cloth, which is commonly uſed in the preſſing of cheeſe. The other ſolid end of the axle-tree muſt extend itſelf about five feet longer; and the whole length may be ſupported by ſquare wooden poſts, and turn in their tops, which are to be made hollow, and kept greaſed for that purpoſe. This end of the axle-tree is to be faſtened into a wheel, exactly like thoſe which are uſed in many places for roaſting of meat. The diameter of this laſt wheel muſt be within ſix inches of the height of the dairy, and two or three large dogs, being put into it at a time, will turn it with extraordinary ſwiftneſs: the dogs are eaſily taught, and will at laſt take delight in the exerciſe. I have brought up a large buck to the practice of this labour, and it is wonderful to ſee the force with which he runs round an hour or two together, and turns a wheel of ten feet diameter; but you muſt make your wheel as light as it can poſſibly hold together. I have but one thing more to ſay, and I finiſh this direction: pretty near that ſide of every ſtall in your ſhed, to which the maid muſt come to milk the cow that belongs to it, let a hole, as ſmall as will ſerve the occaſion, be contrived by your plumber, in the uppermoſt part of the leaden pipe, to ſhut and open with a little ſcrew, which ſcrew, for fear of loſing it, may be faſtened by a little iron chain to the body of the pipe. I have endeavoured, in the deſcription of all this, to make my meaning as plain as poſſible, and hope the reader will, with a little attention, comprehend the whole."

The ingenious Mr. Liſle obſerves, that ſo much cleaning and ſcalding is neceſſary, that the dairy farmers ſpend as much wood in fire, for that purpoſe, during the ſummer, as they burn for other purpoſes in the winter.

If the milk veſſels are not kept clean they will be ſour, and the cheeſe will be ſour before it can come, and it will eat ſour and choaky. A cold dairy is a great means of preſerving cream from turning ſour. The milk-houſes ſhould alſo be large, for otherwiſe the ſteam ariſing from the hot milk as brought in from the cows, will heat the air of the room.

Care ſhould be taken when cows begin to give off their milk, to milk them clean; for if this be neglected they will ſoon grow dry. Cows generally begin to give off the height of their milk about the time of the bloſſoming of the wheat, and continue ſo till a good aftermath comes on, when their milk will increaſe; but cold and rainy weather in the autumn will ſoon abate their milk again. Perhaps the reaſon why the milk of cows abates about wheat bloſſoming time is, becauſe about that time the graſs of the field bloſſoms alſo, and the fluſh of the ſap is come to its height and maturity, and then abates, for the roots of the graſs at that time begin to harden and grow dry; nor do they take in the juices of the earth ſo freely as they did before, and therefore grow drier and drier, till the ſeed is hardened. The ſeed being thus brought to maturity, the roots of the graſs for ſome time, till the cold of the winter checks them, ſtrike freſh ſap roots, or buds, preparative to the enſuing ſpring, and which will the next year be the ſpring roots and increaſe. On theſe new efforts the ſtart of the autumn graſs depends, till the cold checks it. This graſs is called the aftermath, and upon the growth of this the cows milk depends.

It has been obſerved, that the milk of the hill-country cows do not yield the ſame proportion of cream, as that of the vale cows; owing, in all probability, to the poverty of the hill-country cows, which are generally poor in caſe.

Thunder will break the cream, and turn the milk in the milk-pans, ſo that no cream can be ſkimmed off for butter; nor will the cheeſe-curd hold together, but will break aſunder.

It is commonly ſaid, that a quart of cream will make a pound of butter; but this muſt be underſtood of cream, that hath ſtood two or three days to ſettle, for three pints of cream juſt ſkimmed from the milk will, in three days, be reduced to nearly a quart. If you bring in the milk and ſtrain it immediately into the pans, without letting it firſt ſtand to cool, the cream produced by it will be much leſs, than it would have been, if the milk had been ſuffered to ſtand and cool before ſtraining.

In ſome parts of Dorſetſhire they ſet the milk over the fire in braſs pans to warm, which makes the cream riſe, and when a bladdle is formed in the middle, they take the pans from the fire, ſkim off the cream, and put it into a tub. After this the dairy-maid, by only putting her hand, and ſtirring it about in the tub, brings it preſently to butter, without the help of a churn. The butter made by this method is very rich, but the cheeſe made from the ſkim-milk very poor. *See the article* CHEESE.

The hill-country farms are not ſo well adapted to a dairy as thoſe in the vale; becauſe the foddering ſeaſon in the former holds ſo much longer, occaſioned by the rowet-graſs falling off a month ſooner, and the ſpring-graſs coming a month later than in the vale. *Liſle's Huſbandry, vol.* II. *p.* 139.

DAISY, the greater, or *ox-eye*, by ſome called *maudlin-wort*, is the name of a perennial weed common in paſtures. The leaves are jagged, and embrace the ſtalk. The flowers are large, and radiated. The ray is white, and the diſh yellow: the ſeeds have no down.

DALLOP, a tuft, or clump.

DAM, a mole, or bank to confine water.

DAMSON, a ſmall black plum, brought originally from Damaſcus; whence the name.

DANDELION, the name of a very troubleſome and well-known weed in the meadows; and which will ſpread greatly, if the flowers are ſuffered to perfect their ſeeds, which are light, downy, and of courſe eaſily blown about by the wind.

DANEWORK, a name given in ſome counties to that ſpecies of elder, generally called dwarf-elder, or wall-wort.

DANK, damp, humid, moiſt, wet.

DAPPLE, marked with various colours.

DARNEL, *See* COCKLE.

Annual DARNEL-GRASS, called *white darnel* by Gerrard, and in the ſouthern counties *crap*. This plant is ſo much like the *red darnel-graſs*, that it has been greatly cultivated under the name of *ray-graſs*, or vulgarly *rie-graſs*; but the ſpike is much longer and paler; and has beards, which the ray-graſs is entirely without. It is likewiſe annual; whereas the ray-graſs has an abiding root. Its ſeeds ripen with the corn. *See* Plate VII. Fig. 1.

DAWN, the time when the light of the morning firſt appears.

DAY-BREAK, the dawn, the firſt appearance of light.

DAY-WORK, work impoſed by the day. Day-labour.

DEARTH, ſcarcity; a time when food is dear.

DEATH-WATCH, the name of an inſect that makes a ticking noiſe, ſuperſtitiouſly imagined to prognoſticate death.

DECEMBER, the laſt month of the year.

The earth is now commonly locked up under its frozen coat, ſo that the huſbandman has leiſure to ſit and ſpend what ſtore he has before-hand provided.

Now is the time to houſe old cattle, and to fell all ſorts of timber, and other trees, for building, or utenſils; to cut coppices, &c.

Let horſes blood, fatten ſwine, and kill them. Deſtroy ant-hills.

Plough up your land that you deſign for beans, provided it be not frozen too hard; drain corn fields, where the water ſtagnates, and overflow, or water your meadows.

Put your ſheep and ſwine to the peaſe-rick, and fatten them for the market. Cut hedges, and lop trees. *Mortimer's Huſbandry, vol.* II. *p.* 448.

DECIDUOUS, falling, not perennial: an epithet applied to ſuch trees and ſhrubs as ſhed their leaves in the autumn. Thus the oak, the elm, the beech, &c. are called deciduous trees.

DECLIVITY, inclination or declivity, reckoned downwards; gradual deſcent.

DEFICATION, the act of purifying any liquor from its lees or foulneſs.

DELVING, digging, or the act of turning up the earth with a ſpade.

DEMAIN, or *demeſne*, the land which a man holds originally of himſelf. It is alſo ſometimes uſed as a diſtinction between thoſe lands which the lord of the manor hath in his own hands, or in the hands of his leſſee, and ſuch other lands appertaining to the ſaid manor, as belong to free or copy-holders.

DENSHIRING. *See the article* BURN-BAKING.

DEVIL *in a buſh*, or *fennel-flower*, a very troubleſome weed among the corn, eſpecially in Italy, France, and Germany, where it abounds much more than in this country. It riſes with ſlender ſtalks, near a foot high, which ſometimes branch out at the bottom, and ſometimes are ſingle, garniſhed with a few very fine cut leaves, ſomewhat like thoſe of dill. Its flower is generally blue, and its ſeeds are rough and black. This, together with their being nearly of the ſame ſize as the grains of wheat, renders it difficult to ſeparate them from the corn, when the plant has been cut and houſed with it; they blacken the meal, and debaſe its value. The plant is annual, and therefore may be extirpated by rooting it out before it can ſeed, which is commonly in Auguſt.

DEVIL'S-BIT, the name of a weed often found among the corn, but more frequently in meadows. It has a ſtrong, thick, fibrous, perennial root, which runs deep into the ground, and ſends out ſeveral branching ſtalks, which riſe near three feet high. The lower leaves are ſometimes almoſt entire, and at others they are cut into many ſegments almoſt to the mid-rib: they are ſeven or eight inches long, and from three or four broad in the middle, hairy, and ſit cloſe to the root. The ſtalks are covered with ſtiff, prickly hairs, and garniſhed with ſmaller leaves at each joint. The flowers, which are of a pale purple colour, and have a faint odour, appear in June, upon naked foot ſtalks at the end of the branches, which decay to the root every autumn.

DEVIL'S-GUTS, the ſame with the leſſer bind-weed. *See the article* BIND-WEED.

DEVONSHIRING. *See the article* BURN-BAKING.

DEW, the moiſture perceived on the ground, and on the leaves of plants, blades of graſs, &c. in the morning.

Thoſe who have made no other reflections on dew than ſuch as preſent themſelves naturally, think that all the moiſture one finds in the morning on plants and upon the ground, comes in reality from above; but, when the affair is examined with more attention, one ſees that at leaſt a great part of the dew ariſes from the earth itſelf and the plants, and keeps hanging to their ſurface. Mr. Gerſten, who hath made a diſſertation on this ſubject in particular, hath even thought that there fell no dew from above on the ground, and that all which we ſee under the form of dew aroſe from the earth or plants, on which it keeps hanging in pearls, till the heat of the day hath diſperſed it.

For the nature and properties of dew, with regard to vegetation, *ſee the article* ATMOSPHERE.

DEWLAP, the fleſh that hangs down from the throat of oxen.

DIABETES, a morbid copiouſneſs of urine, or the making water in too great quantities. This diſorder is very common in horſes, and often terminates in death.

Horſes ſubject to a diabetes, or profuſe ſtaling, if old, or of a weak conſtitution, are ſeldom cured; they ſoon loſe their fleſh and appetite, grow feeble, their coat ſtaring, and they die rotten. Of a young horſe there are more hopes; but he muſt not be indulged with too much water, or moiſt food. At the ſame time give him the following drink:

> Take jeſuit's bark, four ounces; biſtort and tormentil-root, of each two ounces: boil them in two gallons of lime-water to the conſumption of half, and give a pint three times a day.

Let the horſe drink two or three quarts a day of lime-water; and if theſe medicines ſhould not ſucceed, give a quart of ſtrong alum-poſſet, three or four times a day.

This method is proper alſo for a horſe who ſtales blood; or the following balls may be given for that purpoſe, if the bleeding is profuſe.

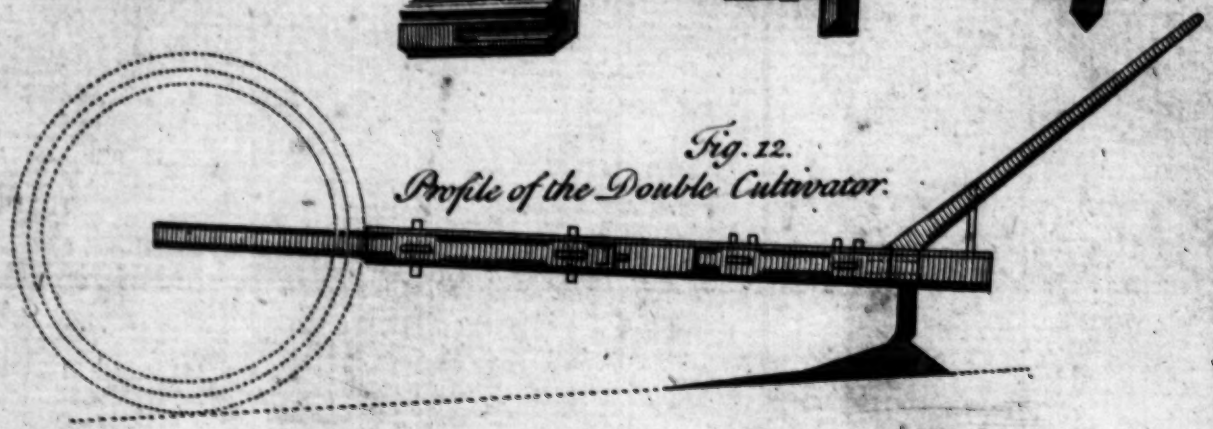
Profile of the Double Cultivator.



Scale of 6 Feet for Fig. 5.

Scale of 6 Feet for Fig. 4. 5. 6. & 7.
Given in Perspective, requires none

Take bole armoniac one ounce, Japan earth half an ounce, roach alum two drams, elixir of vitriol one dram; make them into a ball with conſerve of roſes, and give it every ſix hours.

As this diſorder generally proceeds from too violent exerciſe, over-ſtraining, &c. repeated bleedings in ſmall quantities are abſolutely neceſſary, till the mouths of the veſſels cloſe up. *Bartlet's Farriery, p.* 165.

DIAPHRAGM, midriff, or ſkirt, as ſome call it in a horſe or buttock, is a muſcular ſubſtance that divides the upper cavity or cheſt from the lower belly.

DIBBLE, a ſetting-ſtick, or inſtrument to make holes in the ground for ſetting plants, &c.

DIG, a mattock. *See* MATTOCK.

DIGGING, the act of turning up the earth with a ſpade.

Was labour conſiderably cheaper in England than it is at preſent, and a ſufficient number of hands could be found, it would doubtleſs be the beſt way to dig by hand all the ground deſtined for potatoes, carrots, lucern, &c. many advantages would accrue from this method of tillage; the earth would be looſened to a greater depth, and much better pulveriſed; nor would the weeds and graſs be ſo apt to grow as in ploughed lands.

DIGITATED, branched out into diviſions like fingers.

DIKE, a ditch. It alſo ſignifies a dam ormound to hinder inundations.

DINGLE, a ſmall clough or valley between two ſteep hills.

DITCH, a trench cut in the ground, uſually round the fences of a field.

The mud of ditches affords an excellent manure, as it conſiſts of the putrid particles of animals and vegetables, mixed with the fineſt and richeſt mould; and therefore proves a great improvement to any ſoil, particularly the light and dry. But this mud ſhould be expoſed to the air for ſome time, that the ſeeds of the weeds generally contained in it may have time to vegetate or putrify, before it be laid on the land.

DOCK, the name of a weed, of which there are ſeveral ſpecies, and all of them remarkable for the largeneſs of their leaves; ſo that he muſt be a very ſlovenly farmer who ſuffers any of theſe plants to grow large. They ſhould be plucked up by the roots as ſoon as they appear, which may be eaſily done, as the roots are of the tap, or carrot kind.

DOCKING, the act of cutting off the tails of horſes.

This operation is in general very ſucceſsfully executed, by the common methods, which are known to every farrier. But ſometimes a miſcarriage enſues by an inflammation and gangrene ſucceeding. Theſe accidents probably ariſe from the tendons of the tail ſuffering by an injudicious application of the knife or ſearing-iron, or in an improper ſeaſon for the operation. Neither the very hot or cold months are proper, for reaſons ſufficiently obvious. The operation ſhould always be performed by inciſion, or the chopping engine; the knife being paſſed through the tail from above, whilſt it lays on the block; for when the cutting inſtrument is applied underneath, the blow is given on the tail, which, by bruiſing the tendons, may be naturally ſuſpected to occaſion bad ſymptoms. The ſearing-iron ſhould be ſmooth, and better poliſhed than thoſe generally uſed, and ought to be rubbed clean with a wollen-cloth, before it be applied to the ſtump; otherwiſe the ſparks, which fly from the iron, are apt to occaſion great pain, attended with the ſwelling both of the ſheath and fundament: nor ſhould it ever be applied flaming hot, for then it brings the burnt part away with it, and requires a re-application, in order to form a freſh eſchar on the veſſels; by which means the bone is frequently left too much expoſed, ſo that it is often a conſiderable time before it is covered.

Farriers ſeldom apply any thing to the ſtump; which need only be anointed with the wound ointment, and when the eſchar is digeſted off, may be waſhed with allum or lime-water: but if an inflammation enſues, with a diſcharge of thin matter, a proper digeſtive, compoſed of Venice-turpentine, rubbed with the yolk of an egg and tincture of myrrh, ſhould be applied, with a poultice of bread and milk over it. The rump ſhould be frequently bathed with oil of roſes and vinegar, and a large quantity of blood taken away. If the fundament be at all ſwelled, and the inflammation at all ſuſpected to be communicated to the bowels, let cooling emollient clyſters be injected two or three times a day. Should a gangrene enſue, add Ægyptiacum to your dreſſings, and ſpirits to the fomentation: and apply over all the ſtrong-beer poultice, with London treacle, twice a day. *Bartlet's Farriery, page* 323.

DODDED *Sheep*, ſheep without horns.

DODDER, the name of ſo remarkable a plant, that it cannot eaſily be miſtaken. It is entirely without leaves, and does not depend upon the ground for nouriſhment; but when it is grown up, rots at the bottom, and lives upon the juices of other plants about which it entwines itſelf, by means of threads of a red colour, which it throws out. The flowers are ſmall, and come out in roundiſh heads or bunches, many of them together, here and there, from the ſtem.

DODMAN, a name given in ſome of the northern counties to the ſhell-ſnail.

DODRED *Wheat*, red wheat without beards.

DOG's *Graſs*. *See* COUCH-GRASS.

DOKE, a deep furrow.

DOLE, or *Dool*, a long narrow green in an arable field, left unploughed.

DOLPHIN-*Fly*, the name of an inſect very deſtructive to beans. *See the article* BEANS.

DOOL, the ſame with dole. *See* DOLE.

DOSOME, an epithet applied to ſuch beaſts as improve apace. Thus a thriving beaſt is called, in the northern counties, a doſome beaſt.

DRAGS, a name given in ſome counties to the heavieſt pair of ox-harrows.

DRAFFE, the grains of malt.

DRAIN, a channel, or trench, cut in the earth, in order to carry, or drain off the water. *See the articles* BOG MARSH, and MOOR.

When coarſe graſs is produced, the ground is evidently over charged with moiſture, proceeding either from cold, hungry ſprings, loaded with ſome mineral or acid, which want vent; or elſe from external floods, which, being confined by a ſtiff clay, impervious to water, remain upon it, and corrupt the natural nouriſhment proper for producing the ſweet and richer graſſes. When this laſt is the caſe, the remedy is eaſy, by making proper drains to carry off the ſuperfluous moiſture. But if the

land be ſpouty or ſpewy, as it is commonly termed, and the moiſture ariſes from ſprings, a deep drain muſt be cut in the loweſt part, and ſmaller drains from that principal ditch to ſuch places as appear to be the heads of the ſprings, which will be known by their being wetter and looſer than other parts. The drains muſt be cut deep enough to reach the bed, whether gravel or ſand, through which the water flows; and upon the firſt touching of this, the water will be found to run off more freely, and in greater quantity.

The ſmaller drains, communicating with the main ditch, ſhould be left open for ſome time, until the quantity of moiſture abate. After this, to make them covered drains, by which the ſurface is rendered level, and no part of it is loſt, they ſhould be filled up with ſmall ſtones to within about a foot and a half of the ſurface, and then covered with turf, the green ſide downward, or with heath, broom, ſtraw, or any other thing that can moſt conveniently be had, proper to keep the earth from falling in among the chinks of the ſtones, through which, if no ſuch accident happen, the water will paſs eaſily, the drains will prove effectual, and the plough, after the earth that was turned out is laid above all, will go freely over, without being oppoſed by the ſtones. A foot depth of mould over the drain will be ſufficient in paſture-ground; but this covering ſhould be at leaſt a foot and a half thick in ploughed lands. Where ſtones are ſcarce, faggots made of the branches of any kind of trees are ſubſtituted in their place: but they do not anſwer the purpoſe ſo well, becauſe they decay and rot, the earth falls in, and the drains are ſtopped: though it is highly proper, where theſe are uſed, to line the ſides of the drains with brick or ſtone, without mortar, to keep the earth from falling in there, and at the ſame time give free admittance to the water. It muſt be obſerved, that, where a great quantity of water is to be diſcharged, the main drain into which the ſmaller drains are to empty themſelves, ſhould not by any means be filled up, even with ſtones, unleſs it be both very deep and very wide, and there be a great quantity of ſtones to throw into it, leſt it ſhould not be able to diſcharge all the water; in which caſe the whole work will prove worſe than uſeleſs; a remedy being very difficult on account of the ſtones.

The beſt time of covering theſe drains is about Michaelmas; becauſe the earth is drieſt at that ſeaſon, before the winter rains begin to fall. The digging of them is indeed very laborious work, particularly in marſhes, the ſoil of which is always of a tough, ſtrong quality. It is therefore of great importance, that every means be uſed to leſſen that fatiguing labour. The ſhovels and ſpades univerſally uſed, are certainly too ſhort. Their length ſhould be ſuch as to give the labourer every advantage ariſing from his own ſtrength. In order to have this, he ſhould ſtand as erect as poſſible: for otherwiſe, he has not only the weight of the earth on the ſpade or ſhovel to raiſe, but alſo that of his own body; whereas, if the ſhovel be of a due length, an eaſy ſhifting of the lower-moſt hand becomes a prop, or point, on which the weight at the end is raiſed, almoſt without bending the body.

Where the ground in which the ſprings are lies on a gentle declivity, Mr. Tull very properly adviſes ploughing it nearly horizontally, by which means each furrow carries off the water, which would otherwiſe ſink into the next ridge. If the clay underneath be at ſo ſmall a depth that the plough can reach it, this will have a very good effect: and as the nearly horizontal direction of the furrow gives the water but a ſlow motion, it will not be ſo apt to waſh away the richer mould, as it would if the furrows were more perpendicular to the declivity. Theſe furrows ſhould, however, have ſlope enough to give the water a current ſufficient to prevent its ſoaking into the ridge underneath.

If the ſprings riſe only at the bottom of a ſloping ground, one large drain, reaching the whole length of the declivity, and cut down to the bed of clay underneath, may be ſufficient, with the help of a channel, to carry off the water.

If there is any mineral in the earth, eſpecially a chalybeate, which Dr. Home has experienced to be very prejudicial to vegetation, ſuch mineral, being waſhed out by the ſprings, is lodged in the ſoil, towards the ſurface.

DRAINING *of Land*, the operation of carrying off the water from wet lands. *See the articles* BOG, MARSH, MOOR.

A correſpondent of the editors of the Muſeum Ruſticum has obliged the public with the following obſervations on the uſes of draining.

"The firſt experiment, ſays he, I made, was upon a piece of ground of about four or five acres, in the front of my houſe, of the ſpringy kind; where the waters, collected from the rains and dews in a large plain of dry land above, broke out upon the declivity of the hill, and not having proper drains and channels, to carry them away, had, by long overflowing, rendered the ground ſo ſoft and boggy, as not to allow the tread of any ſort of cattle, (unleſs in very ſevere froſts;) and thereby made it intirely uſeleſs, and alſo very diſagreeable to the eye. I took the opportunity of a very hard and laſting froſt, to carry on a large quantity of ſtones for making the intended drains: which were laid out in the following manner. A main drain, or trench, was made through the middle of the ground, from a ſmall rivulet (into which it was to empty itſelf), to a little above where the ſprings made their firſt appearance: from thence two drains (one on each ſide) were carried along the ſide of a hill to the two extreme parts of the ground, emptying themſelves into the head of the firſt mentioned drain, which was only made about three feet deep till near the top of it. The branches or ſide drains were better than ſix feet, as I hoped thereby to have cut off all the ſprings: but the declivity of the land being conſiderable, I was obliged to add two drains more below: as ſome of the ſprings had eſcaped under the bottoms of the higheſt branches. I made the drains in the following manner. The bottoms were flagged with a thin tender ſtone (of no other uſe;) the ſides walled with rubiſh ſtone (the walls being about five inches aſunder, and five inches high;) and the tops covered with a ſtronger kind of rubbiſh ſtone. Upon the covers, I laid ruſhes and reeds, (the then only produce of the ground) to prevent any dirt or ſoil from getting through the openings of them into the drains; and, laſtly, I filled them up with the moſt perous ſubſtances, dug out to near the height of the ſurface.

"I began this work about the end of March, and had finiſhed it about the end of Auguſt. I very ſoon found the good effects of my labour, the ground being grown

grown ſo hard and ſolid before the middle of October, that I was able to carry on, with carts, a very large heap of compoſt, which I had prepared ready for that purpoſe; conſiſting of freſh litter from the ſtables, virgin earth, ſtreet dirt, coal-aſhes, and lime, well incorporated together by frequent turnings. The next ſummer moſt agreeably ſurpriſed me with as fine a crop of hay, both in reſpect of quantity and quality, as any of the neighbouring grounds could boaſt, (above three loads to the acre:) and the aftermath, or ſecond crop, was full as extraordinary as the firſt. In order to know the profit of the latter exactly, I hurdled it off in ſmall parcels: and, having taken in cattle by the week, found the profit better than twenty ſhillings a ſtatute acre. This ground has kept improving ever ſince; and now affords me three crops every year; viz. ſpring paſturage for my milch-cows and early feeders, a moſt plentiful crop of good hay, and an excellent aftermath; without having had any ſuperinduction beſtowed upon it ſince the firſt, which is eleven years ago. When ſtones cannot be conveniently had, the common flat tiles for the bottoms, and the common brick for the ſides, and covers of the drains, will do very well; and, as bricks are more expeditiouſly laid than the rubbiſh-ſtones, I think they will be full as cheap, if proper clay, and fuel for burning them, can be procured upon eaſy terms. The expence of draining this piece of ground was about five pounds per acre. I have drained many acres of the ſame kind of land ſince, with equal ſucceſs; and at a much leſs expence. Another kind of land, which has fallen within my practice of draining, is what I call the ſour ſpongy land; where there is upon the ſurface a tolerable good mould, for ſix or ſeven inches deep, and below that a ſtiff clay, that will not permit any water to paſs through it; by which means, the ſoil above is ſo ſoaked and chilled, with a conſtant ſurcharge of water, that it is not able to produce any thing but ruſhes, and all the worſt ſpecies of acquatic weeds. As this kind of land is often nearly level, or but gently declining, the firſt ſtep I take, is (by levelling) to find the greateſt fall I can get within any reaſonable diſtance. Then, by the means of iron-rods, (ſuch as are uſed in boring for coals) with a bitt or iron ſcoop at the bottom, I try in ſeveral places the depth of the clayey ſtratum, which ſo obſtructs the paſſage of the water; and alſo what the natures of the ſeveral ſtratums below it are, till I come as low as the level, where I propoſe to begin my drain. If I find, in ſuch ſearch gravel, ſand, ſoft-rock, pinnel, or other porous ſubſtance, I begin the good work immediately, and with full aſſurance of ſucceſs: making a good ſtone or brick drain (as before deſcribed) through the loweſt part of the ground intended to be drained; and then filling it up with the light porous ſubſtances, that ariſe in the digging of it, or any rubbiſh that can be conveniently procured; taking great care that none of the clay, or hard ſubſtances, be thrown in again; and that the top and ſides of the drain be left lower than the reſt of the land; that the winter rains may eaſily deſcend to it, and ſo paſs (as through a ſieve) into the channel prepared to receive them. If there be any low parts in the piece of ground, from whence the rain-water cannot deſcend to the main drain, ſmall pebble, or wood drains, ſhould be made from thoſe low parts into it: taking care to fill them up with ſome rubbiſh or light mould. The clay, which is dug out, may be converted (either by burning or laying up in heaps with quicklime) into a moſt excellent tillage, either for corn or graſs land, for the improvement of the ſame ground, or any other where it is more wanted. For the fertility of ſuch land, after ſuch draining, is greater than can be well imagined by thoſe who have not tried it, even without any further improvement. I generally (indeed) ſet on lime immediately afterwards, if the ſeaſon of the year be proper for it; which, I ſay (from experience), is from the middle of April, to the middle of July; being certain, (notwithſtanding ſome great authorities, and the common practice are againſt me) that twenty buſhels ſet upon graſs-land, during that ſeaſon, are more than equal to thirty laid on in the autumn, or winter ſeaſons. About an hundred and ſixty buſhels to an acre are a proper dreſſing. The laſt kind of land, of which I ſhall now treat, is the black peat or mooriſh land, many thouſand acres of which, in this kingdom, are now intirely uſeleſs, though capable of being improved to great advantage. Nay, I will venture to affirm, that there is ſcarcely any ſo bad, but that it might, by proper means, and due induſtry, be converted to ſome uſeful purpoſe. For which aſſertion, I have a happy authority, in that beautiful teſtimonial of induſtry, given by Virgil, in his fourth Georgic, to the old Corycian farmer. If theſe kinds of land be nearly upon a level, I uſe the precautions mentioned in the laſt article; and, if I find my level will carry me below, or to the bottom of this black mooriſh or peat-earth, I do not regard the depth of my drains, as the digging is very eaſy, and what is thrown out will nearly pay the expence, by being either dried into peat for fuel, or burnt into aſhes; which, if properly managed, are an excellent dreſſing, either for ſpring-corn, or graſs-land. In the draining of this kind of ground, I make one principal drain through the middle of the piece, (of ſtone or bricks, as before mentioned); and, at about every eighty or a hundred yards, branches from it. Theſe I make rather better than two feet wide at the top; and continue them nearly of the ſame width, till within eight or nine inches of the bottom. Then, with a ſpade (about nine inches broad at the top, and narrowing down to three inches) I make a lower drain; and, upon the ſides or ledges (formed by the narrowing of it), lay large heath-ſods, cut ſquare, and exactly to the width of the upper part: by which means, a cavity is left for the water to run in. Upon thoſe ſods or covers, I throw bruſh-wood, or any kind of light trumpery: and, laſtly, I fill it up with the ſmalleſt of the black ſoil thrown out. Such is the preſerving nature of this black peat or earth, to all vegetables buried in it, that there is no doubt, but drains of this laſt kind will endure for ever, if they be laid deep enough. After the ground is drained and levelled, marl (if to be had near) ſhould be laid on; if not, ſand, gravel, or any kind of light earth. If the firſt, no other ſuperinduction will be required; but if any of the latter over it ſhould be ſpread, a cover of ſome of the fineſt black mould, that is pretty free from any ſtrings or fibres; and then a compoſt made of horſe-dung, coal-aſhes, earth, or clay and lime; and, laſtly, it ſhould be laid down either with graſs-ſeeds alone, or with barley (or oats) and graſs-ſeeds. I laid down a piece (drained and managed as above mentioned) about the beginning of Auguſt laſt, with white clover, yellow clover, and common hay-ſeeds, and though the ſeaſon was ſo remarkably dry and hot, yet the young plants came

came up very well, and very thick, and, in this preſent ſevere froſt, it affords a verdure, not to be ſeen any where elſe in the neighbourhood; and the piece is conſtantly covered by my cattle, tempted by the look, and the ſweet food it affords them. I am now preparing about five acres of the ſame kind of land, to be laid down with barley and graſs-ſeeds in the ſpring; and hope (if the ſeaſon proves favourable) to have a good crop of both. I had no marl (or even clay) near, ſo was obliged to make uſe of ſand and gravel for my firſt ſtratum.

DRAINING-PLOUGH, a plough for cutting drains, in order to carry off the water from wet ſoils.

Several inſtruments have been invented for performing this neceſſary operation; but as none were found ſufficient to anſwer the intention of the huſbandman, the Society for the Encouragement of Arts, Manufactures, and Commerce, propoſed a premium of fifty guineas for the beſt plough or machine, of the ſimpleſt conſtruction, that ſhould, with the leaſt force, cut a new drain one foot in depth perpendicular, one foot eight inches wide at the top, and ten inches at bottom; both ſides of the drain equally ſloping, and the earth to be equally thrown out on both ſides. In conſequence of this premium, ſeveral inſtruments for effecting this purpoſe were ſent in to the Society; but upon trial one was found much ſuperior to the reſt, and anſwerable to the Society's advertiſement: and in conſequence of which the premium was adjudged to the author.

This plough, of which we have given four figures on Plate VIII. was made by Mr. Cuthbert Clarke, at Belford, in Northumberland; and anſwered exceeding well in meadow-ground; but could not be drawn in a ſtiff clay with the force of eight horſes. Fig. 1. is a perſpective view of the whole inſtrument ſeen on one ſide. Fig. 2. another view ſeen in front. Fig. 3. a third view ſeen at the tail. Fig. 4. a ſection of the plough, to ſhew the diſpoſition of the three coulters.

Note. The ſame letters refer to the ſame parts in all the four figures; ſo that where any of the parts cannot be ſeen in that figure, the letters will not be found.

A, B, C, are the three coulters.

D, E, F, the nuts and ſcrews that faſten the coulters to the beams.

G, H, I, a wheel, or rather roll, which prevents the plough from going any deeper in the earth. This roll is divided into three parts, by circular pieces of iron, which project beyond the roll; and cut the turf into three parts. The coulters follow in the ſame tract, and finiſh that part of the work.

K, K, the centers on which the roll turns.

L, L, the nut and ſcrews which faſten the iron arbour in which the pivots of the rolls turn to the beams. Theſe arbours are kept in their proper places by means of the two iron braces *f*, *f*.

M, a large iron-hook, to which the chain by which the inſtrument is drawn is faſtened.

N, the tow-chain, or that by which the plough is drawn.

O, the head of the plow into which the beams are mortiſed.

P, Q, R, the three beams.

S, a ſhoe of iron, (the whole part from S to A being of that metal) and into which the hoof of the plough is inſerted.

T, a ſhelf on which the mould riſes after it is cut up by the coulter and fore-part of the ſhare, till it is thrown out of the trench by the mould-boards.

V, V, the mould-boards, which throw the earth out on each ſide of the trench.

W, W, a band of iron, which faſtens the after-part of the plough to the main or middle beam.

X, the head of a tenon, which faſtens the mould-boards, and hoof of the plough to the main beam.

Z, Z, the two handles, like thoſe of a common plough.

a, *b*, a piece of board tenoned into the handles, in order to keep the handles in their proper poſition.

c, *d*, repreſents the ſurface of the ground when the plough is at work. Therefore all the parts below that dotted line are under the ground when the drain is cutting.

f, *e*, *g*, ſhews the angle which the coulters make with a line drawn parallel to the horizontal plane; and is nearly equal to forty-five degrees.

The figures are drawn on a ſcale of an inch to a foot; but many of the parts, being drawn in perſpective, cannot be meaſured.

We imagine it will be unneceſſary to ſay any thing farther with regard to the manner of working this plough, as the operation is the ſame as that with the common plough. But it may not be amiſs to obſerve, that the angle *f*, *e*, *g*, being greater than that by which the horſes draw upwards, the plough has too great a tendency to get into the earth; the conſequence of which is, that, when the ſoil is very ſtiff, and conſequently requires a very great force to draw the plough, the inſtrument cannot be held properly by the handles, the force of ſix men not being ſufficient to do this, but the plough will turn entirely over. This was ſufficiently apparent to the committee of the Society, at the firſt experiment, when the ploughs were tried in a ſtiff clay; for the tail of this very plough could not be kept down by ſix men at the handles. If therefore the angle *f*, *e*, *g*, were leſſened to about thirty-three degrees, this difficulty would, in a great meaſure, be removed. However, in marſhy, boggy, and moory ſoils, it will anſwer the intention extremely well, and make a clean trench of the dimenſions required by the Society; and therefore cannot fail of being a very valuable acquiſition in the practice of agriculture.

DRAPE, a farrow cow, or one whoſe milk is juſt dried up.

DRENCH, phyſick, &c. given to a brute by means of a horn, cut properly for that purpoſe.

DRILL-PLOUGH, an inſtrument for ſowing corn in drills, or rows, which is an eſſential part of the New Huſbandry.

The two firſt inventions for ſowing in this manner were Mr. Worlidge's drill-plough, and Don Joſeph de Lucatello's ſembrador, both of which may claim the merit of inventions, and therefore muſt not be omitted in this work.

"Beſides the uſual method of ſowing corn, there are, ſays Mr. Worlidge, ſeveral other ways of diſperſing it, as by ſetting, and hoeing of it in, &c. This art of ſetting corn ſeems to be very ancient, as appears by Virgil, *Unguibus infodiunt et ipſis fruges.* And hath been a long time attempted to be brought into practice again, as appears by Mr. Platt' Adam's Tool revived." Mr. Worlidge

lidge then points out the defects in Mr. Platt's iuſtruments, and proceeds thus:

" But to remedy and remove all manner of errors and inconveniencies that can be found in ſetting of corn, I ſhall here give you a plain and perfect deſcription of an eaſy and feaſible inſtrument that ſhall diſperſe your corn, grain, pulſe, of what kind ſoever, at what diſtance, and in what proportion you pleaſe to deſign, and that with very great expedition, and very little extraordinary charge, expence, or hazard.

" Firſt make a frame of timber, of about two or three inches ſquare, the breadth of the frame about two feet, the height about eighteen inches, the length about four feet, more or leſs as you pleaſe, as at *u u u u*, Fig. 1. Plate IX. Place this frame on two pair of ordinary wheels, like plow-wheels. The axle-tree of the two foremoſt wheels is to lock on either ſide, as doth the fore axle-tree of a waggon, for reaſons hereafter ſhewn. The hindermoſt axle-tree, being of iron, and ſquare in the middle, muſt be fixed to the center of the wheels, that the axis and wheels may move together: then, about the middle of the frame, in the bottom, let there be fixed an iron inſtrument, or of wood pointed with iron, like unto a coulter, made a little ſpreading at the bottom, in the nature of a ſhare, made to paſs through two mortiſes on the top, for its greater ſtrength; and made alſo to be wedged higher or lower, according as you will have your furrow in depth, as at *o o*; the uſe whereof is only to make the furrow: ſo that you muſt make the point thereof of breadth only to move the earth, and caſt it, or force it, on either ſide, that the corn may fall to the bottom of the furrow. Then, over this, ſhare or coulter, a little behind it, may a wooden pipe be made, to come from the top of the frame to the lower end of the ſhare, tapering downward, as at *p*, and as near as you can to the ſhare: to deliver the corn immediately, as the ground is opened, and before any earth falls in; that what earth does afterwards fall in, may fall on the corn. This pipe is to proceed out of a large hopper fixed on the top of the frame, that may contain about a buſhel, as at *q*: but ſo that the corn may gradually deſcend, according to the quantity you intend to beſtow on an acre. At the very neck of the hopper, underneath, in the ſquare hollow thereof, muſt be fitted in the edge of a wheel of wood, about half an inch thick, and proportioned to the cavity of the neck, as behind the letter *r*. The wheel need not be above two or three inches diameter, and fixed on an axis extending from one ſide of the frame to the other: on which axis is alſo to be another wheel, with a groove on the circumference thereof, like the wheel of a ſpit or jack, as at *r*, which muſt anſwer to another wheel of the like nature and form, fixed on the axis of the hindermoſt of the wheels, as at *s*: then fit a line (of ſilk is beſt, becauſe it will not be ſo apt to ſhrink and reach as hemp) about theſe two wheels, that when the inſtrument moves on the hindermoſt wheels, by the means of the line, the ſmall wheel at the neck of the hopper, may alſo move; which leſſer wheel in the neck of the hopper, may have ſhort pieces of thick leather fixed in the circumference thereof, like unto the teeth of a jack-wheel, that upon its motion it may deduce the corn out of the hopper, in what proportion you pleaſe: for in caſe it comes too faſt, then you may by a wedge at the tenon of the piece whereupon the hopper reſts, as at *t*, or at the end of the axis of the leſſer wheel, force the wheel and hopper together; as, in caſe it feeds too ſlow, then may you remove them by the ſame wedges to a farther diſtance; alſo in caſe your line be too ſlack or too hard, you may prevent either extreme by a wedge in the place where the axis of the wheel moves; or by a third wheel, about the middle of the line, made to move farther or nearer, as you ſee cauſe.

" Alſo by means of the iron-rod *v v*, fixed to the foremoſt axis that is made to lock, may you guide your engine at pleaſure; which rod is made crooked at the end of the hopper, leſt that ſhould injure its motion.

" And at the turning, you may liſt up your engine by the handles at *x*: for whilſt you liſt it up, the corn feeds not until you ſet the ſame down again.

" One horſe and one man may work with this inſtrument, and ſow land as faſt or faſter than ſix horſes can plough; ſo that you may with eaſe compute the expence, in caſe your inſtrument be ſingle: but you may in the ſame frame have two ſhares at twelve inches diſtance, more or leſs, as you will have the rows of corn diſtant the one from the other; and two pipes out of the ſame hopper, and two ſmall wheels on the ſame axis, with other wheels anſwerable, every whit as eaſy to be performed as one; and then you may double your proportion of land in a day.

" This inſtrument will always keep the ſame proportion you firſt ſet it to, which you muſt thus contrive. Firſt, know the length of the furrow you ſow: then caſt up how many of theſe furrows at ſuch diſtance your inſtrument is made for (whether a foot, more or leſs) will amount to an acre; then conclude how much to ſow on an acre; as ſuppoſe a buſhel: then divide that buſhel into ſo many parts as you have furrows or diſtances in that acre: then take one or two of thoſe parts, and put into your hopper, and obſerve whether it will hold out, or ſuperabound at the end of one or two furrows, and accordingly proceed and rectify the feeder: or you may judge by your own reaſon, whether it feed too faſt or too ſlow.

" In caſe it feeds too faſt, notwithſtanding they be cloſe placed together, you may make that wheel at the loweſt axis, wherein the line moves, to be leſs than the upper; then will the motion be ſlower: and thus may you make it move as ſlow as you will, by augmenting the upper, and diminiſhing the lower wheels wherein the line is; and make it move faſter by the contrary rule.

" In caſe you drive apace, it feeds apace: in caſe you drive but ſlow, it feeds but ſlowly: here is no error.

" When you come to any turning at the land's end, by lifting up the hindermoſt part of the inſtrument, that thoſe wheels touch not the ground, the feeding of the corn immediately ceaſeth, until you ſet it down again.

" Alſo all the corn you ſow lies at a certain depth, none too deep, nor any too ſhallow.

" You may place a kind of harrow to follow; but the beſt way is to have on each ſide of each furrow, a peice of wood, a little broad at the end, ſet aſlope to force the earth rounding on the corn. This may be well placed and fitted to the bottom of this inſtrument, juſt behind the ſhare and feeding pipe.

" By this method of ſowing any ſort of grain or pulſe, may be ſaved the one half, and in ſome places more, which by the other way is either buried ſo deep under clods,

clods, that it cannot come up, or elſe is ſo ſhallow, that the cold in the winter, or drought in the ſummer killeth it, or elſe lies on the ſurface as a prey to the fowls of the air: much alſo therefore falls in cluſters, twenty or thirty grains where one or two might ſuffice, which are common inconveniencies, and uſually happening to the vulgar way of ſowing corn: the greater half by far is loſt, which in all probability may be ſaved by the uſe of this very inſtrument, which will doubly requite the extraordinary charge and trouble thereof: for here is no corn ſowed under clods, but in rows, as the earth is ſtirred and moved: it is all at one certain depth and at one certain diſtance, and equally covered, below the injury of froſt, and heat, and rapine of birds. Alſo by this way corn may be ſown in the very middle or convenient depth of the mould, that it may have the ſtrength of the land both below and above the root whilſt in the other more uſual way, the corn falls to the bottom of the furrow on the gravel, clay, or ſuch like hard ground, where it ſeldom thrives ſo well as what happens to be in the midſt. This way alſo exceeds the way of ſetting corn, where the pins thruſt into the ground harden and faſten the mould, ſo that, unleſs the land be very light, it confines the roots to too narrow a place, which in this way is prevented; as I have obſerved in garden beans, that thoſe hoed in proved better than thoſe ſet with a ſtick.

"By the uſe of this inſtrument alſo may you cover your grain or pulſe with any rich compoſt you ſhall prepare for that purpoſe, either with pigeon-dung dry or granulated, or any other ſaline or lixivial ſubſtance, made diſperſeable, which may drop after the corn, and prove an excellent improvement: for we find experimentally, that pigeon's-dung ſown by the hand on wheat or barley mightily advantageth it in the common way of huſbandry: much more then might we expect this way, where the dung, or ſuch like ſubſtance, is all in the ſame furrow with the corn; whereas in the other vulgar way, a great part thereof comes not near it.

"It may either be done by having another hopper on the ſame frame behind that for the corn, wherein the compoſt may be put, and made to drop ſucceſſively after the corn: or it may be ſown by another inſtrument to follow the former, which is the better way, and may both diſperſe the ſoil, and cover both ſoil and ſeed.

"The corn alſo thus ſown in ranges, you may with much more conveniency go between, and either weed it or hoe it, and earth it up as you think good, and at harveſt it will eaſily repay the charges.

"Alſo the fore-wheels being made to lock to and fro on either ſide, you may have an upright iron-pin fixed to the middle of the axis, extended to the top of the frame: and from thence a ſmall rod of iron to come to your hand, with a crooked neck juſt againſt the neck of the hopper; by means of which iron rod, you may lock or turn the wheels either way, and guide your inſtrument, and rectify it, if it deviate out of its right courſe.

"The hopper muſt be broad and ſhallow, that the ſeed preſs not much harder when it is full, than when it is near empty, leſt it ſow not proportionably.

"Though this inſtrument may at firſt ſeem myſterious and intricate to the ignorant, yet I am confident it will anſwer to every particular of what I have written. Any ingenious wheelwright, joiner, or carpenter, may eaſily make it with very little inſtruction, and any ordinary ploughman may uſe it."

The chief inconvenience in this inſtrument ſeems to be, that the ſeed is liable to be bruiſed as it drops from the hopper, by the wheel in the neck of that hopper.

In the account which is given of the ſembrador, in the Philoſophical Tranſactions, it is juſtly obſerved, that the perfection of agriculture conſiſts in ſetting the plants at proper diſtances, in ground well looſened to a ſufficient depth, that their roots may be able to ſpread, in order to collect the nouriſhment which is neceſſary to produce and ripen their fruit. But this is ſo little obſerved, that almoſt all ſorts of ſeed are commonly ſown by handfuls at random; whence it happens, that corn is ſowed too thick in ſome places, too thin in others, and, frequently, the greater part of it is either not covered at all, or not deep enough; by which means it is not only expoſed to be eaten by birds, but alſo in cold countries to be ſpoiled by froſt, and in hot climates, by the ſun. To remedy theſe inconveniences, Don Joſeph de Lucatello invented an inſtrument, which, being faſtened to the tail of the plough, drops the ſeed regularly in the furrow, ſaves four parts in five of the quantity which is generally uſed, and becomes the means of procuring a conſiderable increaſe, without employing a perſon purpoſely to ſow.

As a few words will explain the mechaniſm of this inſtrument, which has its merit, though it has not been found to anſwer in common practice, we ſhall venture to give the following ſhort deſcription of it; becauſe ſome of the principles of this may poſſibly ſuggeſt an uſeful hint to an ingenious artiſt.

Fig. 2. Plate IX. is a box of wood: *a*, *b*, *c*, *d*, the cover of that part into which the corn is put, and which is open in Fig. 3. at W: *e*, *f*, *h*, *g*, *k*, *l*, Fig. 2. are the two ſides which cover that part of the box where the cylinder, which is ſtuck round with three rows of little ſpoons to throw out the grains, is turned round. Theſe ſides are taken off in Fig. 3. to ſhew the cylinder R S, and the ſpoons *x*, *x*, *x*. The internal ſhape of theſe ſides is expreſſed in Fig. 4. where may be ſeen the four triangular pieces *p*, *p*, *p*, *p*, and the triangular interſtices *q*, *q*, *q*, which ſerve to convey the corn diſcharged by the ſpoons, to holes which let it out at the bottom of the box. T, is one of the wheels which turn the cylinder; and V the other end of the cylinder, on which the other wheel is to be fixed. The furrow in which the grain has been dropt is to be covered by the next turn of the plough; to which end the mould-board muſt project conſiderably.

In uſing this inſtrument, according to Don Lucatello's method, it muſt be faſtened to the beam of the plough, at ſuch a height that the long projecting nails in the wheels may touch the ground ſufficiently to make them turn round, but not enough for the wheels to reſt upon it, and drag along without turning.

This way of turning the wheels, and conſequently the cylinder, muſt occaſion an unequal diſtribution of the ſeed, wherever the ground is rough and ſtony. For this reaſon, and on account of ſome other inconveniencies attending the uſe of it, the ſembrador is not an inſtrument to be recommended to farmers: but we would here refer to the conſideration of ſuch as are better ſkilled in theſe matters whether an inſtrument leſs liable to this objection, or to the fault which is found in Mr. Worlidge's drill, may not be formed,

by

by placing the ſeed-box of the ſembrador in a frame like that of Mr. Worlidge, with (inſtead of the wheels of the ſembrador, which turn upon the ground) two wheels, grooved like pullies, fixed upon the axis of the cylinder, to be turned with cords, like the ſmall wheel at the neck of Mr. Worlidge's hopper. A ſquare frame, like that, will keep the box more ſteady, and therefore render the diſcharge of the ſeed more regular, than it can be in Don Lucatello's manner.

M. Duhamel obſerves, that the drill-plough invented by M. de Chateauvieux delivers the grain with the greateſt exactneſs, and therefore deſerves much commendation; but that the price of it is too great for moſt farmers. His own, which we ſhall now deſcribe, has, for that reaſon, been the moſt generally uſed.

M. Duhamel's drill is faſtened to the fore-carriage of a common plough. The hind part conſiſts of a plank S S, Fig. 5. Plate IX. at leaſt three inches thick, which is called the table. Underneath this table, and to the bottom part of it, are ſtrongly fixed, as at T, T, T, three ſhares. The beam I, I, is faſtened to the fore-part of the table: and the handles L, L, are let into mortiſes in the back part of the table, in which they are fixed. *a*, *a*, *a*, are three ſloped cavities cut in the table, to receive the ſeed from the cylinder, and convey it through a hole, about an inch in diameter, in the center of each of them, into the hollow *c*, at the back of the ſhare Fig. 6. The form of theſe cavities is more clearly expreſſed by *a*, *a*, *a*, Fig. 7. At *b*, *b*, *b*, *b*, Fig. 5. are fixed four ſtrong ſtandards, to hold the drill-box ſteady.

The ſhares Fig. 6. are made of wood, and terminate at the bottom of their fore-part *a*, in a circular form, covered with iron. In their hind-part *b* is a groove, through which the ſeed drops to the bottom of the furrow. The ſeed is conveyed from the cavities *a*, *a*, *a*, Fig. 7. to this groove *b*, Fig. 6. by means of a thin plate of iron *c*, rounded and fixed to the ſhare, as at *d*. Theſe ſhares are about an inch and a half thick, and their height from *a* to *b* is at leaſt a foot.

As theſe ſhares terminate in a curve at bottom, if they meet with any roots, dung not thoroughly rotted, or any other ſubſtance which they cannot eaſily divide, they force it down to the bottom of the furrow, and by that means are never liable to be choaked: and to prevent this ſtill more effectually, the middle ſhare is placed ſomewhat more backward than the two others. It is likewiſe made ſhorter, when uſed in land laid out in ridges, in proportion to the greater height of the middle of the ridges. The ſhares are generally ſeven inches aſunder.

The four ſtandards *b*, *b*, *b*, *b*, Fig. 5 and 7, are placed in ſuch a manner, that the blocks *n*, *n*, Fig. 8. in which a groove is cut, anſwer to the middle of this table. On an iron axle-tree which anſwers to the wheels, and which paſſes through the centre of the blocks, is fixed the cylinder, or barrel *o*, *o*, which is cloſed at its ends, *p*, *s*, and is likewiſe divided by two partitions *q*, *r*. This barrel is made of thin ſplit deal, as are alſo the ends and partitions. *t*, *t*, is a thin board, or plate of tin or thin iron, faſtened with hinges, that it may be opened to put the ſeed into the three partitions *p q*, *q r*, *r s*. In the middle of each of theſe partitions, the barrel is pierced with holes three or four inches aſunder, and about a quarter of an inch in diameter. The barrel and the wheels are ſo fixed on the iron axle-tree, that they all turn together.

To know whether the holes *u*, *u*, *u*, in the three partitions of the barrel are of a proper ſize and number to diſtribute the ſeed in the manner that is deſired, let ſome, ſuppoſe half a buſhel, be put into each partition. The blocks *n*, *n*, being placed on each ſide, beween the two ſtandards, whoſe inner ſides are rounded ſo as to fit the groove in the blocks, and the table *S*, *S*, being raiſed ſo that the wheels do not touch the ground, any one may eaſily ſee, by giving the wheels a turn or two round with the hand, whether the proper quantity of ſeed drops behind the ſhare; and alter it accordingly.

The barrel being properly fitted, the beam is faſtened to the fore-carriage of this drill. As it moves, the barrel turns with the hind wheels, and the ſeed drops out of the holes *u*, *u*, *u*, Fig. 8. into the cavities *a*, *a*, *a*, Fig. 7. and from thence into the hollow *c*, Fig. 6. in the hind part of the ſhare.

When the plowman comes to the end of the field, he lifts up the hind carriage, which is light, and carries it till the horſes are turned for the next furrow.

M. Duhamel does not fix the diameter of the hind wheels, but leaves that to be determined by the length of the ſhares. His were ſo proportioned, that when the ſhares touched the ground, the wheels did not touch it by two inches. He obſerves, that this drill anſwered extremely well, where the ground was plowed into an even or level ſurface: but that the wheels were too ſmall when the middle of the ridges was raiſed high; becauſe the ſhares were then on the higher part of the ridge, while the wheels were in the furrows.

In Fig. 7, are two thin boards *x*, *x*, ſomewhat bending, which riſe up to about half the height of the barrel. The uſe of theſe is to catch the ſeeds that may chance to drop from the oblique holes, and guide them into the cavities *a*, *a*, *a*.

It is well known, that when the fore-part of the ſhare terminates in a point, it pierces the deeper into the earth, the farther back the beam is placed on the fore-carriage: but as the botton of theſe ſhares is round, they pierce neither more nor leſs when the beam is placed more forward. It is therefore adviſeable to place the fore and hind carriage as near as poſſible to each other, becauſe the plough then goes eaſier, and the draught is lighter to the cattle.

This inſtrument is eaſily tranſported from place to place by means of two poles *y*, *z*, *z*, Fig. 7. The ends *y* are placed on the fore-carriage, together with the beam, and from thence paſs under the table, ſo as to raiſe the whole from the ground, on which their other ends *z*, *z*, reſt. The croſs bar *k*, *k*, ſecures thoſe ends, and keeps them at a proper diſtance.

M. Duhamel took the firſt hint of his ſeed box from an invention of Mr. Grenvile, a gentleman belonging to the king of France's ſtables. This was a hallow ball, fixed upon the axle-tree of two wheels, and pierced round the middle with a row of holes, through which the ſeed dropt as the wheels turned round. Upon a ſimilar principle, another gentleman, inſtead of ſowing under furrow in the common way, contrived a box to turn behind his plough; and that no more than the due quantity of ſeed ſhould be dropped, the lower half of the box moved upon a belt of leather, in the middle of which was fixed a piece of braſs pierced with a hole ſuited to the ſize of the ſeed intended to be ſown. By this means, the holes in the box could not drop any ſeed, but when they came oppoſite to the

hole

hole in the belt. A few grains were indeed ſometimes bruiſed in their paſſage; but, upon the whole, there was a great ſaving of ſeed.

According to the above conſtruction of M. Duhamel's drill, the ſhares muſt always pierce to the ſame depth, becauſe the whole weight of the hind part of the drill reſts continually upon them: conſequently, it would be neceſſary to have ſhares of as many different lengths, as there are depths at which each kind of ſeed ſhould be ſown.

We likewiſe apprehend, that when the ſhares have pierced to the depth intended, the weight of the drill may be made to reſt on the wheels, by preventing the axle-tree from riſing between the ſtandards, beyond ſuch a height as ſhall exactly regulate the depth to which the ſhares are to pierce. This may be effected, by bringing the ſtandards *b*, *b*, Fig. 7, nearer to each other; and placing between them, inſtead of the blocks, *n*, *n*, Fig. 8. two thick pieces of wood, made to ſlide up and down, with grooves, as in the blocks. Theſe pieces of wood may be fixed between the ſtandards, by means of two ſtrong iron pins run through the ſtandards into them: and to take off the friction of the axle-tree againſt theſe pieces of wood, may be made to turn on two friction wheels, placed in the lower part of them; or rather on four or ſix ſmall iron rollers turning on their axis in a box inſerted in each of theſe pieces, which may be raiſed or lowered, by means of a row of holes in the ſtandards, through which the iron pins are put, ſo as to give the axle-tree room to riſe to the height that ſhall be thought neceſſary to make the ſhares pierce to the intended depth, before the weight of the drill ſhall reſt upon the axle-tree.

That the axle-tree, moving on ſuch roller, will have leſs friction, or require leſs ſtrength to make the wheels turn round, even when the weight of the whole inſtrument lies upon it, than it has in the blocks, with only the weight of the grain, is evident from the following fact. The gentleman who firſt thought of this invention applied it to a roller of four tuns weight, which is now drawn with eaſe by two ordinary horſes, even acroſs his plowed grounds.

It appears from this eaſy motion of the roller, that there can be no danger of the axle-trees turning, though loaded with the weight of the whole inſtrument. Other conſiderable advantages will alſo ariſe from the drill's reſting thus upon the wheels; for the labour of the plowman will be greatly leſſened, the inſtrument will move ſteadier and more uniformly, and the draught will be much eaſier for the horſes.

Deſcription of M. de Chateauvieux's DRILL-PLOUGH, *and of its manner of working. Written by himſelf.*

"When I firſt ſet about conſtructing this drill-plough, my deſign was to make an inſtrument which ſhould diſtribute the grains of corn one by one, at the diſtance of ſix inches from each other. I attained this preciſion; but ſoon perceived that it was not the only thing requiſite, or even ſo neceſſary as I had imagined.

"I could, indeed, make my drill diſtribute ſome grains more than it did in its firſt ſtate: but I plainly found that the quantity of ſeed would not yet be ſufficient to produce a proper number of plants; eſpecially as it muſt not be expected that every ſeed will grow; 1, becauſe, whatever care be taken in chuſing the ſeeds, there will always be among them many which will not ſprout at all; 2, becauſe a great number of them will be deſtroyed by inſects, either before they vegetate, or ſoon after they ſpring up; and 3, becauſe the winter's cold will frequently deſtroy ſeveral of the young plants, and greatly weaken others. Experience taught me, that, to guard againſt the effect of theſe caſualties, it was neceſſary to ſow more ſeed than I did at firſt.

"To this end, and that I might be enabled to increaſe the quantity to whatever degree ſhould be found moſt proper, I enlarged the cavities of my cylinder, ſo that I can now ſow either more or leſs ſeed, with equal eaſe, by means which ſhall be explained in the deſcription of this inſtrument.

"Each of theſe cavities in the cylinder of my firſt drill-plough could contain but one grain of corn; but in the preſent, they are large enough to hold three or four, which, though they touch one another there, are ſo ſeparated when they fall from thence, and in their paſſage through the pipes, that they drop at diſtances from each other in the furrow; for they are not all turned out of the cavities in the cylinder at the ſame time: beſides which, I have obſerved, that the ground upon which they fall is always more or leſs uneven, and that this circumſtance conſequently contributes effectually to ſeparate them.

"I confeſs that the deſcription which I am going to give is very long, and that this, together with the ſight of ſo many figures as are here repreſented, may, at firſt, make people think that my drill is a very complicated machine, and that this complication muſt render it very defective: but I beg of them not to give way to this prejudice, and to ſuſpend their judgment, till they have ſtudied the inſtrument thoroughly; after which, I hope they will be ſenſible that all its menachiſm is employed only to procure the movement of the axis, and the play of the valves. I even flatter myſelf that it will be deemed a ſimple inſtrument, by thoſe who rightly conſider how few of its parts are moved; a circumſtance which prevents its being put out of order in working. The great quantities of land which were ſowed in the autumn, with perfect ſucceſs, ought to remove the diffidence of thoſe who may ſtill incline to doubt whether this drill will always and regularly perform equally well.

"It will perhaps be objected, that the expence of making this drill-plough is too great, and that numbers of farmers, who have not much land, may not be able conveniently to purchaſe it.

"It is very true that if this inſtrument could be conſtructed for a ſmall price, the benefits reſulting from it would be the more extenſive: but it muſt alſo be allowed that this objection does not hold good with reſpect to all farmers, or to gentlemen who keep ground in their own hands. Theſe will ſoon be repaid the expence of ſuch a drill, by the ſaving of ſeed; and as to the poorer ſort, who have, for example, but ten or twelve acres of arable land, the expence will be but trifling, if four or five neighbours, in that caſe, join to purchaſe ſuch a drill, which will be more than ſufficient to ſow all their ground. Or, each pariſh may come to an agreement, that he who can afford to buy ſuch a drill, may let it out for ſo much an acre; a method which would be advantageous to all; but particularly to thoſe who, by uſing it, would ſow their land with very little charge.

"But I think, and hope, that when the great advantage of uſing this inſtrument is known, no huſbandman will be

without

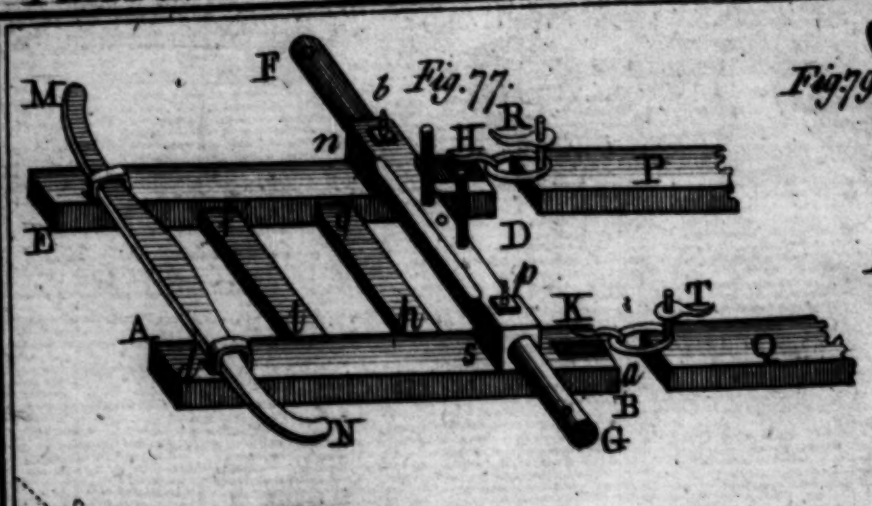
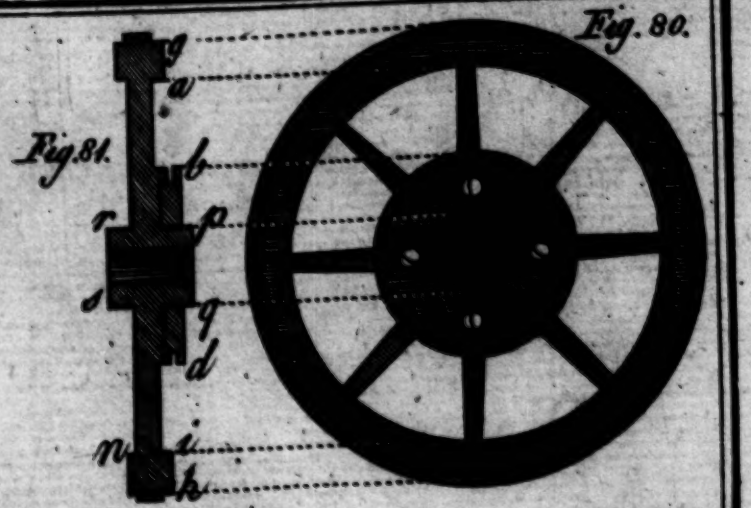
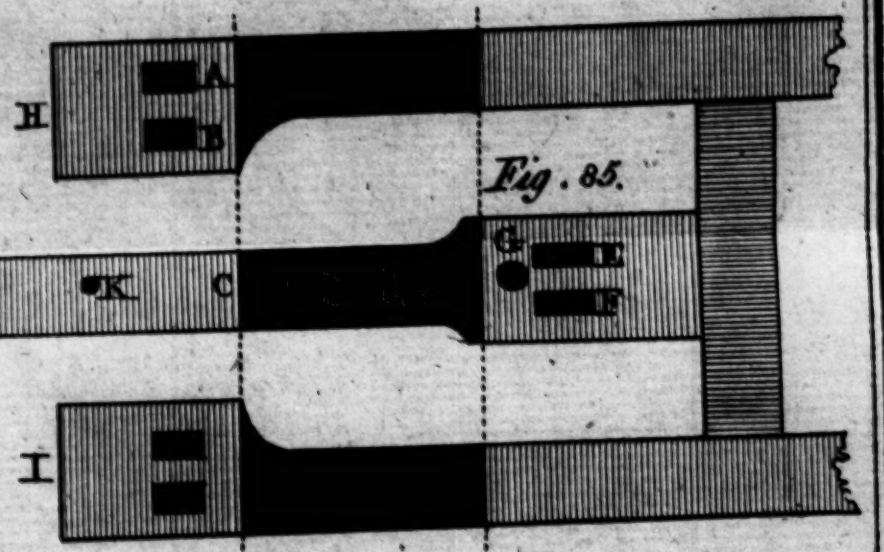
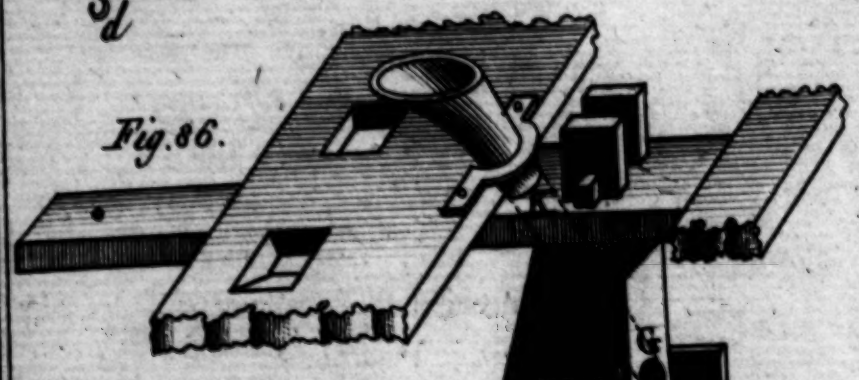
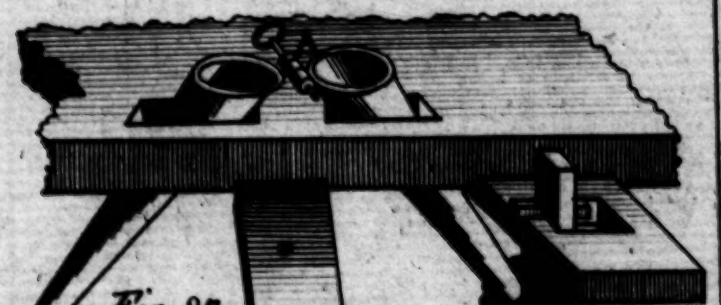
PLATE. XIV.











without it merely becauſe of the price; as this conſideration can never out-weigh the benefits which will accrue from it in all reſpects, by leſſening the expence of every article in the operation of ſowing, and by the farther emoluments which will be reaped at harveſt.

"I therefore, in conſtructing this inſtrument, paid leſs regard to the price which it might coſt, than to the means of rendering it very ſolid, by a firm aſſemblage of all its parts; which was eſſential, in order to prevent the frequent accidents it would otherwiſe have been expoſed to, in the hands of ignorant peaſants, who have no idea of handling things gently, and are ſtill leſs capable of repairing any miſchief done to a very nice machine."

At the ſame time that I ſtudied ſtrength and ſolidity in the conſtruction of this inſtrument, it was not leſs neceſſary to take particular care that it ſhould execute well and regularly the purpoſes for which it is intended, both with reſpect to the manner of its diſtributing each grain, and to the movement of the axis, which is always in motion from the moment that the horſe ſtirs, ſo that the ſeed runs inceſſantly.

In deſcribing this inſtrument, I have firſt given a general idea of its make and manner of working, that the reader may be thereby enabled the more eaſily to underſtand the ſubſequent minute deſcription of all its parts, with their relation to, and connection with, each other. The method of uſing it will then follow.

General idea of M. de Chateauvieux's DRILL-PLOUGH, *Plate* X.

A (Fig. 1.) is a wooden-box, or hopper, whoſe bottom is at the height of the line F G. This hopper has four feet, two of which are ſeen at *k* and *l*. Theſe four feet, which may be called tenons, are fitted into four mortiſes in the table H L. The bottom F G of this hopper reſts immediately upon the ſeed-box B, which is made of thin plates of braſs, and is placed between the bottom of that upper box or hopper, its two ſides which have the four feet, and the table H L. B is the front of this ſeed-box. The corn drops through a hole in the middle of the bottom of the hopper A, into the ſeed-box B. This ſeed-box B contains a braſs cylinder, which traverſes it, and is pierced by and fixed to an iron axis M P, at the two ends of which are firmly faſtened two pullies Q and P. The two pivots of the axies are ſupported by two ſtandards, one of which is ſeen at M H, and a part of the foot of the other at L. Theſe two ſtandards are fixed to the two ends of the table by two keys, like thoſe of a turner's lathe.

The table upon which all theſe pieces reſt, is itſelf, at its two ends, ſupported by, and faſtened to the two beams T V, R S. Theſe two beams are fixed in parallel lines, by a traverſe X Z. In the middle, U, of this traverſe, is pinned the end of another piece of wood, which paſſes from thence under the table, in a parallel direction with the two beams, and upon which alſo this table is faſtened by two ſcrews.

This inſtrument has three exactly ſimilar ſhares, D, K, *e*. Two of theſe ſhares, K and D, are faſtened to the two beams, at I and *p*; by a tenon and a peg, and the third is faſtened in the ſame manner, towards U, to the piece which runs parallel to the beams. Each of theſe ſhares is covered at the bottom with a plate of iron, N, E, C; and the point of one of them, ſuppoſed to be in the earth, is ſeen at Y.

The harrow is compoſed of three pieces of wood *q* O, O W, W *n*, jointed together by mortiſes and tenons at O and W, and of two ſimilar iron teeth W *z*, O R. Theſe two teeth are faſtened to the harrows by the ſcrews W and O, and the harrow is faſtened to the traverſe X Z by two hinges near *q* and *n*. Upon the two beams are faſtened by two ſcrews, at *m* and *e*, two ſquare ſprings *m i q* and *e* Z *n*, of which the two ends *q*, and *n*, preſs upon the harrow, to make its two teeth enter into the earth.

The fore-carriage is compoſed of two ſimilar and parallel pieces V *r*, S *s*, upon which is faſtened the ſpring-tree bar *r s*, and the axle-tree *u t* of the two wheels. The drill (of which the manner of working will be explained hereafter) reſts upon this fore-carriage, whenever there is occaſion for its ſo doing, by means of a wooden bar *d x*, one of the ends of which, towards *a*, paſſes thro' two belts which are faſtened to the table, and of which only one is ſeen here. The other end *x* of this bar, reſts upon the middle of the axle-tree of the fore-carriage, between two pins driven into the upper part of that axle-tree. The fore-carriage is likewiſe faſtened to the drill by hooks and rings, as at *v* and S.

At *t* and *u* are two pullies, which are faſtened to the ſpokes of the wheels by three or four ſcrews. The pullies Q and *u* are encircled by a thong of leather, of the ſame breadth as the grooves of the pullies, and of which the two ends are buckled together, like a garter. The two other pullies P and *t* are encircled in the ſame manner by another ſimilar thong.

Manner in which the DRILL *works, Plate* X.

The ſeed being put into the hopper A (Fig. 1.) the whole machine being drawn by the horſe harneſſed to the ſpring-tree bar *r*, *s*, and guided by the ſeedſman, who holds the two handles; then the three ſhares D, K *e* C, open each of them a furrow, and at the ſame time the pullies *u*, *t*, by their turning, turn, by means of the thongs, the two other pullies Q, P, and conſequently likewiſe the cylinder, which is in the box B, and which, in turning, diſtributes the ſeeds equally into three pipes which come out at the bottom of the ſeed-box. This diſtribution of the ſeed is performed by a mechaniſm which cannot be repreſented here, but will be particularly explained hereafter. The ends of theſe pipes are ſeen here at *a* and *b*. Theſe pipes *a* and *b* drop the ſeeds into two other pipes *d* and *f*. The pipe *a* tranſmits its contents into the pipe *d*, which terminates behind the ſhare D, at *h*, where it depoſits the ſeeds in the furrow made by this ſhare. In the ſame manner, the end of the pipe *b* of the box conveys the ſeed which paſſes through it into the pipe *f*, which terminates at *g*, behind the ſhare K. And likewiſe in the ſame manner, the third pipe of the box, which cannot be ſeen in this figure, empties its contents into a third pipe, of which part is ſeen here at *v*, *y*, and which terminates behind the third ſhare *e*, C. The two teeth of the harrow, paſſing afterward each of them between two of theſe furrows, cover the ſeeds which have dropped into the three furrows.

According as ſcrew B, in the fore-part of the box is turned more or leſs from the right to the left, or from the left to the right, a greater or leſs quantity of ſeed drops into each furrow, by a means which will be ex-

plained hereafter. But ſo long as this ſcrew remains in the ſame ſituation, the quantity of the ſeed that is dropped will be conſtantly the ſame.

To render the deſcription of this firſt figure the more diſtinct and intelligible, ſome things are paſſed over here, which will be ſpoken of hereafter, and among others two traverſes which faſten together the two pieces V *r*, S *s*, of the fore-carriage. Alſo the box B is here made larger than it ſhould be according to the deſcription which will be given of it in order that the pipes *a* and *b*, *d* and *f* might appear the more diſtinctly. For the ſame reaſon alſo the out-lets of the pipes *a* and *b* are not here repreſented as let into the mouths *d* and *f* of the two other pipes, as they ſhould be in fact.

In the following deſcriptions, that part of a piece which immediately faces the horſe, is always called the fore-part of the piece, excepting only the piece named the bin, and its valves, in ſpeaking of which the contrary rule is obſerved. But, every where, the right or the left ſide of a piece, is to be underſtood as of the ſame ſide of the horſe.

When a machine is to be made from drawings, thoſe drawings, eſpecially when ſmall, cannot, by their ſcale, point out preciſely the exact dimenſions of every nice, and oftentimes very important, piece, ſo as to enable a workman to conſtruct it perfectly. To remedy this defect, all the meaſures of every piece, and their connection with each other, are here particularly ſpecified in the written deſcription, which is to be looked upon as a ſurer guide than the meaſures reſulting from the engraved figures: and to render this ſtill more certain, the weight of the niceſt pieces is alſo given.

Deſcription of the two Beams which ſupport the Table and the Hopper, Plate X.

The two beams T V, R S, (Fig. 1,) are repreſented as if ſeen from above at *a*, *b*, *d*, *e*, (Fig. 2.) They are exactly ſimilar. Each of them is three feet five inches and a half long, two inches and five-ſixths wide (for example from *b* to *c*), and one inch five-ſixths thick. All their ſides are at right angles to each other.

Theſe two beams are joined by a traverſe *f h* (Fig. 2.) and X Z (Fig. 1.) This traverſe is two inches and five-ſixths wide, meaſuring it horizontally, one inch and three-twelfths thick, and one foot and a half long, excluſive of two tenons, one at each end, by which it is mortiſed into the two beams, which are parallel to each other. The upper ſurface of theſe beams, and that of their traverſe, are exactly even. The diſtance from *c* to *f* (Fig. 2. Plate XI.) is one foot eleven inches and a quarter; and the ſame from *i* to *h*.

Underneath each beam, and at the diſtance of five inches from the extremity *a* (Fig. 3.) an iron-pin, ſeven-twelfths, or two-thirds of an inch in diameter, projects to the length of four inches and one-third. One of theſe pins is ſeen at Δ (Fig. 1.) Its other end is driven faſt into the middle of the breadth of the under ſurface of the beam, from which it projects perpendicularly. Theſe two pins are to enter into two holes in the axle-tree of the hind-carriage, which will be ſpoken of hereafter.

Of the two Handles, Plate X.

Two handles, *k n*, *l m* (Fig. 2.) are faſtened to the two beams, each of them by a tenon *d*, (Fig. 3. Plate XI.) five-ſixths of an inch thick, which paſſes through the beam, and is ſecured underneath it by a wooden pin or peg *d*, about half an inch in diameter. Each handle is likewiſe ſupported upon the beam by a wooden prop *p l*, which is ſeen at R and T (Fig. 1.) Each of theſe props is three quarters of an inch in diameter, and is driven very tightly into the handle and the beam, at *p* and *l* (Fig. 3, Plate XI.) ſo as to paſs quite through them. The upper end *c* of thoſe props is ſeen at V and X, in Fig. 2. From the extremity *k* of the handle (Fig. 2, and 3,) to the extremity *a* of the beam, is one foot, and one-third of an inch, and the diſtance is the ſame from *d* to *l*, in Fig. 2. The breadth and thickneſs of the lower end of the handles at *g k* (Fig. 2, Plate X. and 3, Plate XI.) is nearly the ſame as the breadth of the beams, upon which they reſt: but they leſſen by degrees from *k* to *n*, and are rounded off, in ſuch manner that the diameter of their upper end *n* is but one inch and a third.

With reſpect to their poſition, they form, with the beams, an angle of 40 degrees, as at *c k a* (Fig. 3, Plate XI.) The handle is nearly ſtrait from *k*, to about a third part of its length, and from thence it bends more and more downward, to its end *n*, which is perpendicularly two feet higher than the upper ſurface *k m* of the beam. This height is expreſſed by the pricked line *n m*. The ſpace between the handles likewiſe increaſes with their length, ſo that, at their ſmalleſt ends, the diſtance from the outſide *m* of the one, to the outſide *n* of the other (Fig. 2, Plate X.) is one foot eight inches and a half, and each of them is equally diſtant from the middle line *o p*.

Theſe two handles are faſtened to each other by a traverſe *q r*, which is repreſented in Fig. 1, but is expreſſed here only by two pricked lines, in order to ſhew a piece which is under it, and which will ſoon be ſpoken of. This traverſe is one inch and five-ſixths broad, and two-thirds of an inch thick. Its ends, being tenons, are let into mortiſes in the beams, and faſtened there by wooden-pins, at *q* and *r*. One of theſe ends appears at *q* (Fig. 3, Plate XI.) From the middle of the length of this traverſe hangs an iron-hook, as in Fig. 1, Plate X. This hook is about a quarter of an inch thick, and five inches and a half long, from its extremity *e* (Fig. 3, Plate XI.) to its other end, which is faſtened to the traverſe. The lower end of this hook is put through a ſmall ring faſtened to the harrow between the ſcrews of the two teeth, and ſerves to hold up the harrow when the drill is placed upon its hind-carriage, in order to be removed, as will be ſaid hereafter. The traverſe is fixed in the handles at the diſtance of thirteen inches from their extremity *k* (Fig. 2, Plate X. and 3, Plate XI.) The two handles, which the ſeedſman holds in his hands by their ends *m n*, ſerve to direct the drill.

Of the Harrow, Plate X.

The harrow is compoſed of three pieces of wood *s t*, *y x*, *t x*, (Fig. 2.) and of two teeth faſtened to this laſt. Theſe three pieces are repreſented at *q* O, O W, and W *n*, and the two teeth at W *z* and O R, in Fig. 1. The two pieces *s t*, *y x*, (Fig. 2.) are each of them faſtened to the traverſe *s y*, by an iron-hinge, in ſuch manner that the upper ſurface of the ends *s* and *y* of theſe two pieces is exactly level with the upper ſurface of the traverſe *s y*. Their two other ends, *t* and *x*, are terminated

minated by a tenon which is pinned into the ends of the traverſe *t x*. The upper ſurface of theſe three pieces *s t*, *y x*, *t x*, is perfectly even.

The two pieces *s t*, *y x*, are each of them one foot eight inches long, from the end *s*, to the traverſe at *t*. They are two inches and one-third broad, meaſuring over their upper ſurface, and one inch and two-thirds thick. The fore-end of theſe pieces towards the hinge makes an angle of about ſixty-five degrees, with the upper ſurface, as is repreſented in the profile (Fig. 4.) where the lines *d a*, *a b*, expreſs this angle. This ſlope is made, in order that the harrow may the more eaſily preſs upon the ground, by moving on its hinges; and for the ſame reaſon all friction between the ſides of the harrow and thoſe of the beams is avoided, by leaving an interval of about one-ſixth, or one quarter of an inch between them. The lines, or edges *t s*, *x y*, (Fig. 2.) are parallel, and the diſtance between them is one foot and five-ſixths of an inch. The traverſe *t x* is two inches and nineteen twenty-fourths wide, and one inch and two thirds thick.

In the middle of the breadth of the upper ſurface of this traverſe, and cut perpendicularly to that ſurface, are two ſquare holes, M and N, diſtant from each other ſeven inches and a half, from the center of one to the center of the other, and both equally diſtant from the middle line *o p*.

Of the Teeth of the Harrow, Plate X.

In theſe two holes M N in the traverſe of the harrow are faſtened, as will ſoon be ſeen, two iron-teeth, perfectly alike, ſo that it will be ſufficient to deſcribe one of them. This tooth is ſhaped almoſt like the head of a lance, if we ſuppoſe its two ſides to be bent towards each other, ſo as to form a kind of groove or channel. Theſe two ſides, or fins, are ſeen in perſpective, ſideways in Fig. 5, behind in Fig. 6, from above, and from before, in Fig. 7.

The ſhank *b d* (Fig. 5.) is five inches and an half long, from its riſe at *a b*, to its end *d*; and three quarters of an inch thick at *a b*, where it is made ſquare. This thickneſs is increaſed a little at *c*, in order to form the ſhoulder repreſented at *a b* (Fig. 7.) The diſtance from *a b* (Fig. 5.) to this ſhoulder *c*, is three inches. The ſquare thickneſs of the ſhank, from *c* to *n*, is half an inch; which is likewiſe the ſize of the holes M N (Fig. 2.) The reſt of the ſhank is round, and half an inch in diameter. Its upper end is a ſcrew, fitted to receive a nut about half an inch thick, and a little more than an inch ſquare. The point *e* does not vary from the direction of the ſhank, either to the right or the left, as appears by Fig. 6: but the ſide *b e* (Fig. 5.) bends a little forward, ſo that the point *e* advances one inch and a quarter beyond the pricked perpendicular *n b f*. The upper and outer extremities *e* and *f* of the fins (Fig. 7.) are two inches and one-twelfth diſtant from each other, and equally diſtant from the middle of the ſhank. The width of each fin, in this part, from *s* to *f*, or from *s* to *c*, is one inch and a half. From thence they leſſen by degrees down to their point. The edges of theſe ſides, or fins, are almoſt ſharp, but their thickneſs and ſtrength increaſe towards their back.

The two teeth of the harrow are placed exactly in the middle of two parallel lines ſuppoſed to be drawn from the point of the ſhares, by which means theſe teeth will enter into the ground at equal diſtances from the ſmall furrows made by the ſhares, into which they will throw back the quantity of earth neceſſary to cover the ſeeds perfectly.

As to the poſition of theſe two teeth, they are faſtened in the two holes M and N of the traverſe *t x* (Fig. 2.) as is repreſented by the perſpective view of them in Fig. 8. The ſhank of each tooth is run through the holes in the traverſe *x t*; its ſhoulder is thruſt up cloſe to the under ſurface of this traverſe; and a nut, under which is placed a very thin plate of iron, fixes at the top. The back and point of theſe two pieces ſhould face exactly the fore-part of the drill.

Hinges of the Harrow, Plate X.

To return to the hinges *s* and *y* (Fig. 2.) which are exactly alike, and which are ſeen at *q* and *n* in Fig. 1. Their breadth is one inch and two-thirds, during their whole length, from *v* to *f* (Fig. 2.) The joint *s*, of this hinge, is half an inch in diameter. The claw, from the joint *s* to *f*, is two inches and a quarter long, and is faſtened to the traverſe *f h* by a thumb-ſcrew repreſented in perſpective in Fig. 9, and which ſcrews into a nut *a b*, which is faſtened to the bottom of the traverſe, by two nails. This ſcrew (Fig. 9.) is one-third of an inch in diameter. It is ſcrewed down, by means of a correſponding ſcrew in the nut under the traverſe, till its ſhoulder *c n*, which is two-thirds of an inch in diameter, preſſes upon the claw of the hinge: for which ſee alſo Fig. 4. The length of the other claw of the hinge *s v* (Fig. 2.) from the joint *s* to its end *v*, is four inches and a half. The thickneſs of each claw towards the joint, is a quarter of an inch, and from thence that thickneſs leſſens by degrees to the end *v*. The claw *s v* is faſtened to the piece *s t* by two flat-headed ſcrews.

Spring of the Harrow, Plate X.

Upon this claw, and between theſe two ſcrews, preſſes the end B of a ſpring A *z* (Fig. 2.) which forms an angle at A, and is faſtened to the beam *a b*, between D and *z*, by two flat-headed ſcrews, of which the laſt D is two inches and an half diſtant from the end *z* of the ſpring. Theſe two ſprings are ſeen at *m i e* Z *n* in Fig. 1. The length of this ſpring from *z* to A (Fig. 2.) is thirteen inches and a half, and from the angle A to B two inches and a quarter. Its breadth at *z* is one inch and a half; at N it is one inch and one-twelfth; and at B it is thirteen twenty-fourths of an inch. Its thickneſs at *z* is five twenty-fourths of an inch, and from thence that thickneſs diminiſhes to A, where it is but one-ſixth of an inch. The part A B increaſes in thickneſs from A to B, where it has a head, which alone preſſes upon the claw of the hinge between the two flat-headed ſcrews. This part of the ſpring, with its head, is repreſented plainly, in perſpective, in Fig. 10. When this ſpring is in its ſtate of reſt, the whole of its under ſurface from N to *z* (Fig. 2.) lies exactly flat upon the upper ſurface of the beam. The end *z* of this ſpring is fifteen inches from the end *b* of the beam *b*. Theſe ſprings ſhould be made of good well-hammered ſtuff, prepared like that which is uſed for the ſprings of coaches; by which means they will have a body, and not be ſubject to break or bend. If they appear to be too week, they may be placed a little far-

ther from the joint of the hinge, in which caſe they will the better preſs the teeth of the harrow down into the ground.

Connection of the Beames, with the Table and the Shares, Plate X.

The thickneſs of a quarter of an inch is taken off from the upper ſurface of each of the two beams, from *z* (Fig. 2.) immediately adjoining to the end of the ſpring, to Q, in the one; and from E to F in the other; being, in length, eight inches and two thirds. In theſe lowered ſpaces is placed the table, which will ſoon be ſpoken of, and of which the extent is here indicated by pricked lines. This table is ſeen at H and L, in Fig. 1. It is faſtened to the beams, by four ſtrong flat-headed ſcrews, at *z*, I, G, and H (Fig. 2.) and is ſeen in profile in Fig. 3, Plate II. at *i* and *r*. This table reſts likewiſe upon a piece K L (Fig. 2.) of which the end K, being a tenon, is pinned into the middle of the length of the traverſe *f h*; as is alſo ſeen at U (Fig. 1.) This piece K L (Fig. 2.) is two inches and five ſixths broad, meaſuring it horizontally, and one inch and five ſixths thick. Its length is ſuch, that its end L reaches, at moſt, no farther than the edge Q F of the table. At the end of this piece appears a ring, which is faſtened under it, and of which the deſcription and uſe will be ſeen hereafter. The upper ſurface of this piece K L, from K to Y, is level with the upper ſurface of the two beams, and the traverſe *f h*: but from Y to its end, a quarter of an inch is taken off from its thickneſs, in the ſame manner as from the oppoſite parts of the two beams, to fit it for the reception of the under ſurface of the table. A ſide view of this is given in Fig. 11. where *a b* is the profile of this ſurface, which, from *a* to *b*, is level with the ſurface *d a* of the traverſe, and from *b*, to its end *c*, is a quarter of an inch lower, that the table may reſt upon it.

In the middle of the breadth of the upper ſurface of this piece K L (Fig. 2.) and perpendicular to that ſurface, a mortiſe P is cut quite through it, to receive the tenon which is ſeen at U, Fig. 1. This mortiſe is throughout two inches long, and one inch wide. Its end P (Fig. 2.) is three inches and eleven twelfths diſtant from the traverſe *f h*. Theſe two beams are pierced in the ſame manner by two ſimilar mortiſes Q and R, of which the ends Q and R are one inch and eleven twelfths diſtant from the ſide S T of the table. The tenons which paſs through theſe two mortiſes are ſeen at I and *p* in Fig. 1. Theſe three mortiſes are to receive the tenons of three exactly ſimilar ſhares, of which the following is the deſcription. Theſe three ſhares are ſeen at D, K, and *e* in Fig. 1.

Of the Shares, Plate XI.

The ſhares are cut out of a plank, and Fig. 12. repreſents one of their two ſurfaces. The lines which limit this ſurface are perpendicular to each other, excepting *i d*; the line *d c* is ſix inches long; *c f*, nine inches; *f g*, two inches and a quarter; *g l*, five inches and a half; *l m*, two inches; and *h i*, half an inch. This plank is every where an inch thick, except at the edge *e d*, where it forms an acute angle, as at *b*, Fig. 13. which repreſents the bottom of the plank *c d* (Fig. 12.) The part *g l*, in which is the hole *k*, is the tenon which enters into the mortiſes P, Q, R, (Fig. 2.) before deſcribed. Fig. 14. repreſents the top of this plank, and of its tenon.

Fig. 15, is a perſpective view of an iron ſhare which is fixed under the plank, as in Fig. 17. Its point (Fig. 15.) extends from *e h* to *f*. Its ſole, which extends from *c h* to *a c*, and the ears *a b*, *c d*, are all of one piece. Fig. 16 repreſents a geometrical plan of this ſhare, in which *d f*, and *g h*, are the places from whence the two ears ariſe.

The length of the point from *e h* to *f* (Fig. 15.) and from *a b* to *c* (Fig. 16.) is four inches. Its height towards *h*, or towards *e* (Fig. 15.) is about one inch and a quarter, and from thence it leſſens gradually to *f*, which is the point. Its breadth *a b* (Fig. 16.) is the ſame as the thickneſs *c o* (Fig. 13.) of the plank of the ſhare, and it leſſens gradually from thence to its point *c* (Fig. 16.) A notch is made in the upper part of this point, between *e* and *h* (Fig. 15.) or between *a* and *b* (Fig. 16.) to receive the lower end of the angular ſide, *o b c* (Fig. 13.) of the plank.

The ſole *e a* (Fig. 15.) or *a d* (Fig. 16.) is of the ſame length and breadth as at the bottom *c m*, or *o n* (Fig. 13.) of the plank which it covers. It is about, but not more than two thirds of an inch thick towards *e h* (Fig. 15.) and half an inch thick at its end *a c*.

Towards this end are the two thin iron ears, which lie cloſe to the two ſides of the plank, to which they are faſtened by a ſingle nail, which paſſes through the plank, as at *b*, Fig. 17.

This ſhare is alſo faſtened to the bottom of the plank by a flat-headed iron pin, *g h*, Fig. 15. which goes through the ſhare at *n*, and enters into the middle of the thickneſs of the plank. The head *h* of this pin is flat, and lies even with the bottom of the ſole, in the manner indicated by the pricked lines at *a*, Fig. 17. Towards the flat end *c* of this pin is a hole, through which, and through the plank, a ſmaller pin or nail is driven, as is denoted by the pricked circle in the ſame figure.

The point of the ſhare, and the bottom of the ſole, which rubs upon the ground, ſhould be of ſteel. The different thickneſſes given to the ſole, ſhew that its point inclines a little downward, by which means it enters into the earth very eaſily.

Fig. 18. repreſents a perſpective view of a thin plate of iron, which is to cover the plank of the ſhare, as in Fig. 20. to preſerve it from the friction of the ground, which would otherwiſe ſoon wear it out. The thickneſs of this plate, which ſhould be equal every where, is at moſt one twelfth of an inch. It is bent at *a b*, Fig. 18. in ſuch manner that this bending fits cloſe to the ſharpened edge *c d*, Fig. 20. of the plank; the angle *b*, Fig. 18. being fitted to the notch *c* (Fig. 20.) in the iron part of the ſhare, and the lower edges *b c*, *a d*, of this plate (Fig. 18.) joining on both ſides to the upper edges of the ſole of the ſhare, as in Fig. 20. The breadth of this plate from *a* to *b* (Fig. 20.) is about four inches, and each half of its length, from *c* to *a*, or from *d* to *b*, is about ſeven inches and a half. Fig. 19 is the plan, or bottom of this plate.

As this plate covers the ears of the ſhare, and at the ſame time its own angle *c* (Fig. 20.) is covered by the point of the ſhare, theſe two pieces muſt be put on together. This plate is nailed to the two oppoſite ſides of the plank.

The two ends of this plate extend beyond the hindmoſt part of the plank of the ſhare, in the proportion of *b h*,

Fig.

Fig. 20: and in this ſpace, between theſe two ends, is the opening of the pipe through which the ſeed drops into the furrow, as was ſaid before.

The tenon *l g* (Fig. 12.) of the ſhare now deſcribed, (and there are three ſuch) enters into one of the three mortiſes, P, Q, R (Fig. 2.) through the bottom of which it is paſſed, and is fixed above by a wedge driven into the hole *k* (Fig. 12.) Theſe ſhares are ſituated in ſuch manner, that their point faces directly to the fore-part of the drill. One of them is repreſented as fixed towards the end *b* of one of the beams, in Fig. 3, which exhibits the profile of that beam.

Of the Piece which is placed under the Middle of the Table, and which bears the Middle Share, Plate XI.

The piece K L (Fig. 2, Plate X.) which has been already ſpoken of, is repreſented with its bottom upward, and in perſpective, at *a b*, Fig. 21. Plate XI. with the ſhare A, and its tenon B, and with the table, which are alſo inverted in the ſame manner. Fig. 22. is a geometrical repreſentation of the under ſide of the ſame piece, and of part of the table, excepting the ſhare which is omitted here, and of which only the bottom of the mortiſe is ſeen at B.

At the end L of this piece (Fig. 22.) is faſtened the reign, or bridle before mentioned. This bridle is ſhaped nearly like a horſe ſhoe; the breadth of each of its branches is three fourths or five ſixths of an inch; its total breadth is the ſame as that of the piece to which it is faſtened; its total length is three inches and a half, and its thickneſs every where is about one ſixth of an inch. The whole thickneſs of the two branches of this brible is let into the piece of wood to which it is faſtened; ſo that it forms an even ſurface. This bridle is faſtened to the piece by two flat-headed ſcrews, which lie even with the branches of the bridle, through and into which they are ſcrewed. It is placed in ſuch a manner, that the outſide of its circular part L, is one inch and a quarter diſtant from the edge *e f* of the table. It is uſed only when the drill is put upon its hind-carriage.

a and *b* are the heads of two large flat-headed ſcrews, which paſs through the piece K L, and fix it to the table. From the center of the head *b*, to the edge *c d* of the table, is one inch and two thirds. From the center of the head *a*, to the edge *e f* of the table, is one inch and one third. Theſe two ſcrews are placed in the middle of the branch of this piece L. K. Their diameter is five twelfths of an inch, and that of their head is an inch and a twelfth. Theſe heads are flat, and ſcrew in a level with the wood.

Of the two Bridles which receive the End of the Bar which ſupports the Drill upon its Hind-carriage, Plate XI.

Underneath this piece K L, are likewiſe faſtened two bridles very like each other. They are repreſented in perſpective by the ſingle figure 23; but both of them may be ſeen in their proper places, at *g h* and *e f*, Fig. 21. Their place in Fig. 22 is marked only by pricked lines, in order to let the pieces under them be ſeen. Theſe two bridles are made of a flat piece of iron, one inch and a ſixth wide from *a* to *b*, or from *c* to *d* (Fig. 23.) and a very little more than one ſixth of an inch thick. They are bent ſquare at *c d* and *f g*, and are pierced with two holes, *b* and *e*, one fourth of an inch in diameter, of which the centers are three fourths of an inch from the ends of the iron. Thus far theſe two bridles are like each other. What they differ in, is as follows. That which is placed at *g h* (Fig. 21.) is three inches and one ſixth high, from its bottom *a*, to the upper ſurface of its top *c*, or from *e f*, Fig. 23; and this height in the belt which is placed at *e f* (Fig. 21.) is three inches and five twelfts: That which is placed at *g h*, is two inches and five ſixths long, from its outſide at *c d*, to its outſide at *g f* (Fig. 23.) and this part of the bridle placed at *e f*, is three inches and one third.

Both theſe bridles placed at *g h* and *e f* (Fig. 21.) go over the piece of wood *a b*, to which their ends are faſtened by flat headed ſcrews, which paſs through the holes *b* and *e* (Fig. 23.) beforementioned. Theſe ends reſt immediately upon the table. As the diſtance between the ends of the bridle *e f* is exactly equal to the breadth of the piece to which they are faſtened, they are applied to the two lateral ſurfaces of that piece, without being let into it: but as the bridle *g h* is not quite ſo long, the ends of this are let into thoſe ſurfaces, as is ſeen in Fig. 21. and in the pricked plan of theſe two bridles, *h i*, *k n*, Fig. 22. The end of theſe bridles ſtand perpendicular to the table. The bridle *g h*, Fig. 21, is one inch and fifteen twenty-fourths from the edge *t s* of the table; and the bridle *e f* is five inches and eleven twelfts diſtant from the ſame edge *t s*.

The uſe of theſe two bridles is to receive the end of the bar hereafter deſcribed, which ſerves to ſupport the drill upon its fore-carriage, when the hind-carriage is joined to it: and to prevent this end of the bar from ſlipping out of theſe bridles, a moveable iron pin is put through it. This pin is ſuſpended by a piece of pack-thread. It paſſes through the bridle L (Fig. 2. Plate X. and 22. Plate XI) and *b* (Fig. 21.) before deſcribed.

Of the upper Surface of the Table, Plate XI.

Fig. 24. repreſents a geometrical plan of the upper ſurface of the table, one end of which is omitted, as ſuperfluous in this figure, becauſe both its ends are alike. The pricked line *l b* is traced here only to mark the middle of the table, and determine ſome meaſures. The fore-ends of the beams appear here at *f* and *g*, with their mortices A and B, into which their ſhares are faſtend. C, D, E, F, are the four large flat-headed ſcrews which faſten the table to the beams. The diameter of theſe ſcrews towards their head is five twelfts of an inch, that of their head is one inch and a twelfth, and their length is three inches and ſeven twelfths. They enter into the middle of the breadth of the beams, and the centers of the holes in the tables through which they paſs, are eleven twelfths of an inch diſtant from the neareſt edges of the table. The whole breadth of the table, at C D, or E F, is eight inches and two thirds. The two corners G and H are thirteen inches diſtant from the middle line *l b*, and the end K is one foot three inches and three fourths diſtant from the ſame line *l b*. The thickneſs of this table is every where one inch and two thirds.

At each end of the table is a notch K L P, of which the inner ſurfaces are perpendicular to each other. Theſe notches are at H and L in Fig. 1. Plate X. Each of them is three inches and three quarters, from K to L, Fig. 24. and one inch ſeven twelfths wide from L to P. They are ſituated in the middle of the breadth of the table. Their uſe is to receive the lower end of two ſtandards hereafter deſcribed (Fig. 34.) of which one is ſeen at M H, Fig. 1. and the baſe of the other towards L.

This

This table has two holes, M and N (Fig. 24.) of which the upper openings are exactly equal, and alike ſituated, each of them forms a right-angled parallelogram *a h i n*. The ſide *h i* is parellel to the edge D F of the table, from which it is one inch and a half diſtant, and its length is three inches and a quarter.

The upper edge of the end *a n* is eleven twelfths of an inch diſtant from the middle line *l b*, and its length is one inch and eleven twelfths. The inner and parellel ſides *a h*, *n i*, of theſe holes are perpendicular to the upper ſurface of the table; but their ends *a n*, *h i*, are ſloped, in ſuch manner, that each of them forms an angle of fifty or fifty-five degrees toward the line *l b*. This is expreſſed in the profile of theſe two holes (Fig. 25.) by the angles *b a d*, *b c e*, and *g o f*, *g n h*, each of which has that meaſure.

Q, R, S, T, are four mortices, of equal ſize and depth, cut perpendicularly to the upper ſurface of the table. Each of them is nineteen twenty-fourths of an inch long, in the ſame direction as the length of the table, two thirds of an inch wide, and about one inch deep. They are intended to receive the four feet of the hopper, which will be deſcribed hereafter. Two of theſe feet are ſeen in their mortiſes at *k* and *l*, Fig 1 Plate X. The centre of each of theſe mortiſes is ſix inches and five twelfths diſtant from the line *l b* (Fig. 24) and an inch and three quarters from the edges C E, D F, of the table.

Of the Bridles which receive the End of the Bar which ſupports the Drill upon its Fore-carriage, Plate XI.

From *k* to F, Fig. 24. is a bridle which is ſeen in front in Fig. 26. It is made of iron, one inch, or one inch and a twelfth broad, and one ſixth of an inch thick. It is bent in a ſemi-circle at *a c b*, and lies flat upon the table at its end *a* and *b*, which are faſtened to it by two flat-headed ſcrews *a* and *b*, Fig. 26. and *k m*, Fig. 24. This bridle is perpendicular to the upper ſurface of the table. The higheſt part of the upper ſide of its arch *c*, Fig. 26. is two inches above the table; and its width, from outſide to outſide, from *e* to *i*, is two inches and a half. The length of each ſtrait part, or claw, which is faſtened to the table, is one inch and a quarter. The centers of the ſcrews *k* and *m* (Fig. 24.) are each one inch and three quarters from the middle line *l b*, and four inches from the edge D F of the table.

d r q (Fig. 26.) is the upright of another bridle, of which the top, or upper ſurface, is ſeen at *x d p q*, Fig. 24. the front and ſide in the perſpective figure 27, and the back and ſides in the perſpective figure 28. The hinder ſurface of the two claws, repreſented at *a* and *c* (Fig. 28.) is ſcrewed on to the fore-ſurface of the table, as at *f g* and *h k*, Fig. 26. by two flat-headed ſcrews, each of which is one inch and ſeven twelfths long, and near a quarter of an inch in diameter towards its head, which is half an inch in diameter. The middle of this bridle anſwers to the middle of the length of the table. The under ſurface of the bridle, and of its wings, anſwers to the plane of the fore ſurface of the table, to which it is faſtened. The length of each wing is about two inches and a half; their breadth is five ſixths, and their thickneſs a quarter of an inch. The length and thickneſs of its arched part are equal to thoſe of the wings. The bending of that part is ſuch as is repreſented at *g d r q h*, Fig. 26. The diſtance *g h* between the two wings is one inch and eleven twelfths. The greateſt width of the bridle, from outſide to outſide, as at *d q*, is two inches and three fourths; and, laſtly, the upper ſurface of its higheſt part *r*, is one inch and two thirds above the upper ſurface of the table.

The uſe of theſe two bridles is to receive the end of the bar, which will be deſcribed hereafter. This bar is ſeen at *x d*, Fig. 1, Plate X. where one of the rings appears towards *d*. A wooden wedge *o t* (Fig. 24. plate XI.) is ſlipped, if there be occaſion for it, between this bar and the table, to which laſt it is faſtened by a ſingle flat-headed ſcrew *t*, around which it turns, as around a center. The ſhape and extent of this wedge is ſuch as is here repreſented according to the ſcale. Its thickneſs, throughout, is ſeven twelfths of an inch, excepting only at the part *r o e*, where its upper ſurface inclines from *r*, to *o e*, in ſuch manner, that the edge *o e* is almoſt ſharp, that it may ſlide, like a wedge, under the end of the abovementioned bar, which paſſes through the two bridles or belts. The length of this piece is five inches and one twelfth, from the center *t*, to its end *a e*. This center *t* is ſix inches and one ſixth from the edge D F of the table, and four inches and a quarter diſtant from the middle line *l b*. We ſhall hereafter ſee, that the bar which enters into the two belts now deſcribed, ought not to fill entirely the belt *a b c*, Fig. 26. but ſhould leave room to introduce under it the wedge juſt ſpoken of, which is not to be inſerted but when it is intended to make the other end of the bar preſs hard upon the axle-tree of the fore-carriage, which ſhould never be done at the time of ſowing, unleſs the huſbandman would ſcarcely bury the ſeed.

Of the two Pipes of the Shares of the Beams, Plate XI.

Through the two holes M and N of the table (Fig. 24) paſs two braſs pipes, which deſcend to, and open at, the back of the ſheers faſtened in the mortiſes A and B of the two beams. Theſe pipes are ſeen at *d* and *f* in Fig. 1. from whence they paſs through the two holes in the table, and terminate behind the two ſhares D and K, as is repreſented in perſpective in Fig. 29. Theſe two pipes *f p a i k*, and *o r n l*, (Fig. 29.) are perfectly alike. They are almoſt ſquare during their whole length; wider towards the end *f d*, than towards the end *k*; and they are made of plates of braſs, ſomewhat leſs than a twelfth of an inch thick, well ſoldered together. Their opening at *f d* forms a parallelogram, which is an inch and one ſixth wide from *b* to *f*, and an inch and three quarters long from *b* to *d*. The plane or perpendicular projection of theſe openings in the table, is indicated in Fig. 24. by the pricked lines between the letters M and N, where it is to be obſerved, that they are both equally diſtant from the middle line *l b*, and an inch and a half from the edge D F of the table. All the rims of theſe openings, *f*, *b*, *d*, *h*, *o*, (Fig. 29.) are nearly parellel to the upper ſurface of the table, above which they riſe two inches and two thirds. As theſe two pipes are alike, and ſituated in the ſame manner, one on the right, and the other on the left hand ſide of the drill, it will be ſufficient to apply to one of them, what remains to be ſaid of both. This pipe runs in a ſtrait, but oblique line, from its opening *f d* to *i*, directly behind and under the ſhare, from whence its direction becomes perpendicular to its other opening *k*, which is at the height of three inches and a quarter from the bottom *g* of the ſhare. From its bending at *i*, to the opening *k*, is three inches. This

opening

opening *k* is a ſquare, of which the ſides are two thirds, or three quarters of an inch long.

This pipe is held to the ſide *p* of the hole, by a piece of iron which is under the table; and it is alſo faſtened near the bending *i*, by another piece of iron fixed under the beam. Theſe faſtenings are ſeen in Fig. 30. which repreſents, in perſpective, the bottom C D of the table, E F of the beam on the right-hand ſide of the drill, and the ſhare G which is faſtened to it. *q l* is the upper opening of the pipe, which runs from thence cloſe to the ſide *a b* of the hole of the table, where it is faſtened by a plate of iron, *n x*, about one eighth of an inch thick. In this plate is a notch which fits cloſe to three ſides of this pipe. This plate is faſtened to the under ſurface of the table, by two flat-headed ſcrews, *x* and *n*. The pipe continues in the ſame direction from its upper opening *q l*, to its bending at *e*, behind the ſhare; but from thence to *f*, it follows the direction of the back of this ſhare. It is faſtened towards this bending by an iron ſquare, *k i h g*, the thickneſs of which is about one eighth of an inch. This ſquare is faſtened under the beam by two flat-headed ſcrews, *k* and *i*, and to the pipe by two other ſcrews, *g* and *h*, the ends of which ſcrew into a piece of iron, which is ſoldered to the pipe, and which is ſeen between the ſquare and the pipe, from *f* to *e*. The beam A B has a ſhallow notch at *d*, to make room for the paſſage of the pipe.

Of the Pipe of the middle Share, Plate XI.

The two pipes which terminate behind the two ſhares faſtened near the ends of the beam at Q and R (Fig. 2, Plate X.) have now been deſcribed. A third pipe, of nearly the ſame form, terminates behind the third ſhare, which is faſtened at P, in the piece K L. This is the pipe which paſſes between U and *y*, in order to its terminating behind the ſhare *e* C.

This piece K L is repreſented in perſpective at A B, Fig. 31, Plate XI. which ſhews its right ſide, with its ſhare C, and the portion of the middle of the table, where are the two holes D, E, through which paſs the two pipes beforementioned.

This third pipe is made like the two others, of plates of braſs, of the ſame thickneſs and the ſame ſhape. Its opening *b l* forms a parallelogram of nearly the ſame ſize as the ſimilar openings of the two other pipes. The plane of this opening, or its perpendicular projection, upon the table, is indicated by pricked lines near *o c e*, Fig. 24. where it is to be obſerved, that the middle of this parallelogram is in the middle line *l b* of the table, and that its ſide *c e* is five inches and five twelfths diſtant from the edge D F of the table. The rims of this opening *b l* (Fig. 31.) are raiſed about two inches above the upper ſurface of the table. From thence this pipe deſcends in a ſtrait, but oblique line, towards the ſhare which is behind the table; and at the ſame time bears to the right to *d* and *c*, where it bends, in order to take the direction of the lateral ſurface of the piece A B, againſt which it reſts. From thence it continues in this direction to *r*, where it bends again, to *p*, immediately behind the ſhare; and there it is bent again, ſo as to deſcend perpendiculary behind this ſhare, down to *k*, which is within three inches and a quarter of the bottom of the ſhare G.

The table is notched at H, to let in one ſide of the pipe. This notch is alſo ſeen at R, in Fig. 24. The pipe is faſtened in this place by an iron plate *e f*, Fig. 31. about one eighth of an inch thick, which is fixed upon the table by two flat-headed ſcrews near *e* and *f*. This piece is repreſented by itſelf in Fig. 32. *m n*, Fig. 31. is a piece of iron, at leaſt one ſixth of an inch thick, faſtened by two ſcrews, at N, againſt the ſide of the piece of wood A B, into which the thickneſs of this iron is let, as may be ſeen at *m*, in ſuch manner that the outward ſurface of this piece *m n*, is level with that of the piece of wood A B. The pipe is faſtened againſt this piece of iron *m n*, by a belt fixed by two ſcrews to the piece of iron *m n*. This belt is repreſented by itſelf in Fig. 33.

Of the Standards, Plate XI.

In the notches Æ W at the two ends of the table, Fig. 2. Plate X. are placed two ſtandards, repreſented in perſpective in Fig. 34. Plate XI. with the two ends of the table, of which the middle is ſuppreſſed, as needleſs in this repreſentation. Theſe two ſtandards being exactly alike, it will be ſufficient to deſcribe one of them.

In each ſtandard may be diſtinguiſhed three parts, namely, the head, which reaches from the line *p a* to the top of the moulding *b d s*; the baſs, which extends from the top *b d s* of the moulding, to the under part of the ſhoulder *f u q*; and the tail or tenon, which begins at the bottom of the ſhoulder.

All the ſides of this ſtandard are at right angles to each other, excepting only the two indentures *p* and *a* in the head, and the mouldings at the baſe. The inner ſurface A B, which faces the other ſtandard, is every where an even plane.

The head is three inches and a quarter wide, from *b* to *d*; two inches and one ſixth thick, from *d* to *s*; and ſeven inches high, from the line *b d* to the line *p a*.

The baſe is four inches and five ſixths wide from *f* to *u*; two inches and five ſixths thick from *u* to *q*; and two inches and a half in perpendicular height from *f u* to *b d*.

The tail or tenon, which proceeds from the lower middle of the baſe, is equal in breadth *g h*, to the breadth *u q* of the baſe, that is to ſay, it is two inches and five ſixths wide. Its length, *t g*, is ſix inches and a quarter. Its thickneſs is the ſame as the width P L (Fig. 24.) of the notch in the end of the table, which receives the tenon; that is to ſay, one inch and ſeven twelfths. The hole or mortiſe *k n* is in the middle of the breadth of the tenon, and forms a right angled parallelogram, two inches long from *m* to *k*, and eleven twelfths of an inch wide from *n* to *m*. The height of this hole is determined by the thickneſs of the table, in ſuch manner, that the diſtance between the bottom *f u q* of the baſe, to the top *n m* of the hole, is ſomewhat leſs than the thickneſs of the table.

Each ſtandard is faſtened to the table, as may be ſeen in the figure, in the ſame manner as a common turning lathe is faſtened, by a key D, about eight inches and a half long, driven tightly up to its middle, in that part of the mortiſe which is under the table; and for greater ſolidity, one of the keys is put in at the fore part of one mortiſe, and the other at the hind part of the other.

A round hole, one inch and five twelfths in diameter, is bored through the head of the ſtandard, near A. The center or axis of this hole is exactly in the middle of the breadth of the head, and the hole is made through it exactly horizontal to the upper ſurface of the table, or, in other words, perpendicular to the ſide of the ſtandard. The pipe *n o* of the ferrule, Fig. 35. is put into this hole

The

The diameter of this pipe is the ſame as that of the hole. The pipe *n o*, is of one piece with its ſcutcheon *a b d*, which is one-third of an inch thick: its breadth *a b* is one inch and five-ſixths, and its length *b d* is three inches. All its ſurfaces are at right angles, and parallel to each other. The axis of this pipe is in the middle of its ſcutcheon, and perpendicular to its ſurface. Both the ſcutcheon and the pipe (being but one piece) are bored through with the ſame hole, which is five-ſixths of an inch in diameter; and in the upper ſurface of the inſide of this hole is a groove, which reaches from one end to the other. One end of it is ſeen at *n*, and its uſe will ſoon then be ſhewn. The end *n o* of this pipe is put into the hole A of the ſtandard (Fig. 34.) at the inner ſide A B of this ſtandard, and the ſcutcheon *a b d* (Fig. 35.) is let into this ſurface at *c i* (Fig. 34.) where it is faſtened by two ſcrews, of which the ends are ſeen at *c* and *i*, in this figure, and at *e* and *r* in the adjoining repreſentation of the outſide of the other ſtandard. The two ſmall holes in the ſcutcheon are female ſcrews, to receive the ends of the ſcrews before mentioned, which are one-third of an inch in diameter, and their heads is two-thirds. The outer ſurface *c i* of the ſcutcheon is made to lie exactly even with the inner ſurface of the ſtandard, and the center of its pipe is at the perpendicular height of five inches, and ſeven-twelfths above the ſurface of the table. Theſe two pipes (one in each ſtandard) are deſtined to receive the two pivots *a b*, *g h*, of an iron axis; and the groove *n*, (Fig. 35.) then becomes uſeful, by affording the means of introducing a little oil, to keep the pivots from loſing their temper by their friction, and to make them turn with the greater eaſe.

The ſcutcheon and its pipe ſhould be caſt in one piece of good metal, ſufficiently hard, but by no means brittle.

Of the Axis, and the Pieces which are faſtened to it, Plate XII.

The pivots are of the ſame diameter as their holes; and their ſhoulders *b* and *h* (Fig. 36.) are at the ſame diſtance from each other as the inner ſurfaces of the ſtandards, that is to ſay, two feet.

The axis is repreſented naked in Fig. 36; but the ſeveral pieces repreſented ſeparately in figures 37, 38, 40, 41, 42, 43, 44, 45, and 46, are to be faſtened to it.

Fig. 39, repreſents all theſe pieces fixed upon the axis. It is to be obſerved here, that the long pivot *c* (Fig. 39.) goes through the hole of the ſtandard which is on the left-hand ſide of the drill, and the pivot *r* through the ſtandard on the right-hand; ſo that all theſe figures exhibit a front view of the axis and its pieces.

The pivot *a b* (Fig. 36.) on the right-hand ſide, is one inch and a quarter long; and that on the left, *b g*, about two inches. The diameter of the axis towards the ſhoulder *b* and *h* is one inch and a twenty-fourth part of an inch. From thence it thickens gradually to near the middle of its length, in order to facilitate the fixing of the pieces which are to be ſlipped on, over its two ends. In the middle, its diameter is one inch and an eighth.

The firſt piece which is ſlipped over its end *g* (Fig. 36.) is repreſented in perſpective in Fig. 37: a ſection of it is ſeen in Fig. 38, and it appears in profile at *g a b q* in Fig. 39. It is a hollow cylinder, of which the outer diameter *a b* (Fig. 37.) is one inch and thirteen twenty-fourths of an inch. It has a ſhoulder, of which the total diameter *e d* (Fig. 38.) or *g q* (Fig. 39.) is three inches and five twelfths. Its thickneſs from *a* to *b* (Fig. 38.) is ſeventeen twenty-fourths of an inch; and the thickneſs *n m* of the ſhoulder is one-ſixth of an inch. This hollow cylinder and its ſhoulder are made of the ſame piece of braſs, caſt in a mould, and afterwards turned. The diameter of the hollow of this cylinder is the ſame as that of the middle of the axis, upon which it goes very tightly, and is faſtened, as in Fig. 39, by a riveted pin *n*, one-ſixth of an inch in diameter, which paſſes through the axis and the cylinder. This cylinder is placed in ſuch manner that its rim *a b* is eight inches and fifteen twenty-fourths of an inch diſtant from the ſhoulder *e* of the axis Fig. 39, or from the ſhoulder *h* (Fig. 36.)

After this cylinder is firmly fixed, another hollow cylinder, repreſented in perſpective in Fig. 40, is forced over the end *g* of the axis Fig. 36. Its end *g* is put on firſt, and forced forward, till the edge of its other opening *a b* (Fig. 40.) is about a twelfth part of an inch beyond the ſhoulder *h* of the axis Fig. 36. The reaſon for putting it thus a little beyond the ſhoulder *h*, is, that it may not touch the pipe of the ſtandard when it turns.

This cylinder (Fig. 40.) has, nearly in the middle of its length, a ſhoulder, of which the flat ſide *f d*, which is alſo repreſented in full view in Fig. 41, forms a circle perpendicular to the axis of the cylinder. This circle or ſhoulder is four inches in diameter, and a quarter of an inch thick towards its edge; but it is thicker towards the middle, as is ſeen in its profile at *d* (Fig. 39.) The whole length of the cylinder between its two ends *a b* and *g* (Fig. 40.) is three inches; and the diameter of its thickneſs at each end, *a b* and *c*, is one inch and five-twelfths: the length *n a*, from the end *a b* to the flat ſide *d f* of the ſhoulder, is one inch and nine twenty-fourths.

This cylinder and its ſhoulder are of one piece of braſs, caſt in a mould, and turned in a turner's lathe. When put upon the axis, over which it goes very tight, in ſuch manner that, as was ſaid before, its end *a b* (Fig. 40.) is placed about a twelfth part of an inch within the ſhoulder *b* of the axis (Fig. 36.) It is faſtened by a pin which goes in at the hole *c* (Fig. 40.) and paſſes through the axis. This pin, which is of iron, and one-ſixth of an inch in diameter, goes tight through the cylinder and the axis, without projecting at either of its ends. This cylinder is repreſented as pinned at N (Eig. 39.)

Fig. 42, is a wooden pully, of which a part is ſeen at (P Fig. 1, Plate X.) and of which the hole in its center is of the ſame diameter as the end *a b* of the cylinder (Fig. 40, Plate XII.) This end of that cylinder is put through this pully, which is every where one inch and a quarter thick, that is to ſay, ſomewhat leſs than the length of the end *n a* of the cylinder (Fig. 40;) ſo that when the pully is put upon the cylinder, and its ſide is placed againſt the ſhoulder *d f*, the end *a b* of the cylinder projects a little beyond the other ſide of the pully, to prevent its rubbing againſt the adjoining ſtandard. This pully is repreſented in profile at *l m* (Fig. 39.) Its extreme diameter, *f k*, is eight inches; and its groove *l m*, which is ſquare, is an inch and a quarter

quarter deep, and three quarters of an inch wide. This pully is placed close to the brass scutcheon, to which it is fastened by three screws A, B, C, (Fig. 42.) which screw into the three holes *a*, *b*, *c*, (these being female screws) in the flat part of the shoulder (Fig. 41.) of the cylinder (Fig. 40.) Each of these screws (Fig. 42.) is from a quarter to a third part of an inch in diameter; and their head, which is flat, is about a quarter of an inch thick, and two-thirds of an inch in diameter. These heads are screwed into the holes *a b* and *c*, till they lie even with the surface of the pully on that side.

To the other end *b* of the axis (Fig. 36.) is fitted exactly, though so as to slip on with ease, a third hollow cylinder (Fig. 43.) of which the profile is seen at *b* (Fig. 39.) It is like that which is marked N *d* at the other end of the axis; with this only difference, that the extreme diameter of the end *b e* of the cylinder (Fig. 43.) is about two inches. This cylinder is fastened to the axis by a thumb-screw *e*, which goes through a female screw in the cylinder, and of which the end enters into the hole *l* in the axis (Fig. 36.) which is not a female screw: and that the end of the screw may be directed to this hole, without any difficulty, when the cylinder is upon the axis, this last is provided with a small tongue *k*, which goes exactly into the notch *f*, (Fig. 43) as is seen at *e*, (Fig. 39.)

A pully exactly like the former is fastened to the shoulder of this cylinder, by three similar screws, and in the same manner: observing equally here, that the outer surface of this pully do not rub against its adjoining standard. This pully is seen at Q, (Fig. 1. Plate X.)

It is sometimes necessary to take this pully and the cylinder off from the end *r* of the axis (Fig. 39.) which is the reason why this cylinder is fastened by a screw, and not by a pin, like the other. They are taken off, to make room for putting upon the axis the cellular cylinder, which is of cast brass, and turned in a lathe.

Of the cellular Cylinder, Plate XII.

This cylinder is seen in profile, upon the axis, at *p*, *y*, *g*, *q*, *t*, *z*, (Fig. 39.) and in perspective in Fig. 44. Fig. 45 represents its longitudinal section. The part of this cylinder which is between the two lines *y t* and *p z*, (Fig. 39.) is exactly like the above described cylinder Fig. 37 and 38, and *g*, *a*, *b*, *q*, (Fig. 39.)

The only difference between them is, that the one is fixed permanently to the axis, by a pin *n*, (Fig. 39.) and the other is fastened by a screw *v*, which passes through a female screw near the end of the cylinder, which is strengthened there for that purpose, by a moulding or collar *p z*. The end of this screw enters into a hole *m* in the axis (Fig. 36.) but this hole is not a screw. The other part of the cellular cylinder included between the two lines *y t* and *g q*, (Fig. 39.) is three inches and five-twelfths long; its outward diameter, throughout this length, is two inches and twenty-one twenty-fourths of an inch: and its inner diameter is two inches and a third. This inner diameter is a little wider towards the end *b c* of the cylinder, (Fig. 44 and 45.) It is exactly the same as the outer diameter of the projecting part *c d* of Fig. 37, which is to go into, and fit closely to, the end *b c* of the cellular cylinder, (Fig. 44.) so that the edge of this end *b c* may run quite up to the flat side of the shoulder of Fig. 37. The pricked lines in Fig. 45 and 38, are intended to express the correspondence of the parts of these two cylinders, which are to be united, by putting the end of one into the end of the other. Fig. 39 shews the cellular cylinder joined to the shoulder of the other cylinder: in which position it is that the cellular cylinder is fastened to the axis by the screw *v*, as before said: and that the end of this screw may be directed strait to the hole in the axis, whenever this cylinder is put on, two contiguous lines or marks may be made, one upon the edge *p z* of the cylinder, and the other upon the axis.

Of the Cavities of the cellular Cylinder, Plate XII.

On the surface of this cylinder, between the lines *y t*, and *g q* (Fig. 39.) are scooped hollows or cavities, represented at large in Fig. 47, N°. 1, and seen in profile in Fig. 47, N°. 2. They are shaped nearly like a niche, which terminates in a cone at its top, and is rounded gradually deeper and deeper down to its bottom, which is a flat, perpendicular to the lowest part of the cavity.

To conceive and fix the position of these cavities upon the cylinder, the two pricked lines *i x*, *o s* (Fig. 41.) must be drawn round the cylinder, at equal distances from the lines *y t*, and *g q*, and distant from each other two inches and one-third, which is the inner breadth of the seed-box in which the cylinder is placed, as will be more particularly explained in the description of it.

The breadth between the lines *i x*, and *o s*, must then be divided into six equal spaces, by five other parallel lines drawn round the cylinder. Each of these spaces marks the width of each row of cavities; and these six rows of cavities must face exactly the six valves of the bin, which will soon be spoken of.

After this, the places must be marked for twelve similar cavities, placed at equal distances from each other, in each of the breadths traced round the cylinder; observing, that the length of the cavities is to be in the same direction as those breadths; and also, that the flat end of each cavity must be undermost, and the rounded end uppermost, when the cylinder fronts the fore-part of the drill, which is the view represented in Fig. 39; for it is the flat end of the cavities that is to go foremost, when the cylinder turns and drops the seed.

It is likewise to be observed, that each cavity should be opposite to the interval between two cavities in the next adjoining rows, as they are placed in Fig. 39, 44, and 47.

It will be right to have two or three, or even more, cellular cylinders, equally fitted to the axis (Fig. 39.) but with cavities of different sizes, in order to be thereby enabled either to sow more or less seed, or smaller or larger seeds, such as barley, lentils, pease, beans, millet, oats, &c. for each of which its proper cylinder should be used.

The cavities in Fig. 47, N° 1 and 2, are of a size fit for wheat, barley, lentils: for millet, they must be much smaller; for pease, somewhat deeper; for oats, there should be but eight or nine cavities in each row, in order that those cavities may be made longer than for wheat, on account of the length of the oat, which is the only seed that I have found less easy to sow than wheat: the reasons are, the lightness of oats, their not slipping easily between each other, and their having at

one end of the grain a pretty long, flexible, and elaſtic point. Theſe obſtacles ſometimes hinder the grains from entering into the cavities, and the ſeedſman muſt be more careful when he ſows oats, than when he ſows any other kind of grain; though, notwithſtanding theſe difficulties, I have had them ſown pretty well.

To ſow beans, the cylinder muſt have but three rows of cavities, of a length, breadth, and depth proportioned to the ſize of the beans. The bin, which has ſix valves for wheat, ſhould have but three for beans, and theſe valves ſhould be proportioned to the breadth of the cavities, which muſt be placed exactly oppoſite to them, as for wheat.

The following rule will determine the proper ſize of the cavities, by applying, as may eaſily be done, what is here ſaid of wheat to any other kind of grain.

The cavities muſt be large enough to contain three or four grains of wheat, and their depth muſt be ſuch that theſe grains do not riſe above the ſurface of the cylinder, in order that when the cavities filled with ſeeds, paſs under the valves of the bin, the grains may not fall out of the cavities. This will be ſtill better underſtood, after reading the deſcription of the ſeed-box.

Of the Seed-Box, Plate XII. *and* XIII.

After unſcrewing and taking off from the axis, the pully A B (Fig. 39.) its cylinder *h*, and the cellular cylinder *p z*, *g q*; the ſeed-box (Fig. 48.) is placed upon the axis, by running the barred end of this laſt through a round hole in each of the two parallel ſides of the ſeed-box. The diameter of theſe holes is the ſame as that of the cellular cylinder, which is then to be put over the axis, by paſſing its proper end through the hole to the ſide of the ſeed-box, which it traverſes, and faſtening it in the manner before directed. The pully is alſo then to be replaced. The front of this box is ſeen at B (Fig. 1, Plate X.)

Fig. 49 repreſents the box and the cellular cylinder placed upon the axis, where it is to be obſerved that the outer breadth of the box, expreſſed by the interval between the lines *d c* and *k l*, is exactly the ſame as the length of the cylinder expreſſed in Fig. 39, by the diſtance between the lines or ſhoulders *y t*, and *g q*; ſo that the box is held between theſe two ſhoulders *y t*, and *g q*. It is alſo to be obſerved, that the inner breadth of the box, expreſſed by the interval between the lines *f g*, and *h i*, in Fig. 49, is exactly the ſame as the length of the cylinder expreſſed by the lines *i x*, and *o s*, in Fig. 39.

This braſs-box has neither cover nor bottom, but is formed of four plates, each five twenty-fourths of an inch thick. Fig. 50 repreſents the inſide of the plate F G, (Fig. 48.) which is on the left-hand ſide of the drill, with the pieces which the box contains, and a ſection of the cylinder, lengthways of one of the rows of cavities. Fig. 51 repreſents the outſide of the plate oppoſite to the former, and which conſequently is on the right-hand ſide of the drill.

Theſe two plates (Fig. 50 and 51.) are exactly equal. Each of them forms a parallelogram, of which the length A B (Fig. 50 and 51.) is four inches and eleven twelfths, and the breadth B E four inches and fifteen twenty-fourths. Both of them are perforated by a large round hole, of the ſame diameter as that part of the cylinder in which are the cavities. The centre of this hole is in the middle of the breadth of theſe plates, and the upper extremity *b*, of this hole (Fig. 50 and 51,) is an inch and one-ſixth diſtant from the upper edge, D A, of the plate. Both the plates have four mortiſes, G, H, K, L, (Fig. 51.) the breadth of which is equal to the thickneſs of the plates, and the length about half an inch; though this laſt is almoſt arbitrary. Both of them have alſo, directly facing each other, a hole at *n* (Fig. 50 and 51,) three twenty-fourths of an inch diameter, and of which the center at the diſtance of five twenty-fourths of an inch from the line D A, and half an inch from the line A B. The inner ſurface of both the plates is even; and laſtly, each of them has, on its outer ſurface, a ſhoulder which projects round the rim of the great hole. One of theſe ſhoulders is ſeen in perſpective in Fig. 48. The profile of one of them is ſeen between the lines *d c* and *f g* (Fig. 49.) and that of the other between the lines *h i* and *k l*. Fig. 54 repreſents a ſection of them both. The thickneſs of this ſhoulder, that is to ſay, the diſtance to which it is to project, has already been determined by the total diſtance between the lines *y t* and *g q* (Fig. 39.) When the inner ſurfaces of theſe two plates (Fig. 50 and 51.) are laid againſt each other, their edges and holes, now deſcribed, ſhould coincide exactly.

What they differ in is, firſt, that one of them (Fig. 51.) has a ſmall opening M N, which the other has not, and which will be deſcribed in its proper place; and ſecondly, that the hole *n* (Fig. 50 and 51.) is a female ſcrew in Fig. 50, to receive the end of a ſcrew which traverſes the box, but is not wormed in that manner in Fig. 51, where the outſide of the plate is hollowed a little around this hole, to make room for the flat head of this ſcrew, which will be ſpoken of hereafter.

The two plates now deſcribed are fixed in their proper places by means of two others (Fig. 55 and 56.) which laſt are of equal ſize with each other. D E (Fig. 50.) is the profile of Fig. 55, which is the back of the box; and A B (Fig. 50.) is the profile of Fig. 56, which is the front of the box repreſented at A (Fig. 48 and 49.)

The two tenons A and B (Fig. 55.) enter into the two mortiſes which are hid near G and H in Fig. 50. The two other tenons C and D (Fig. 55.) are expreſſed near G H in Fig. 50, and receive the mortiſes G and H of Fig. 51. In like manner the two tenons E and F of Fig. 56, enter into the mortiſes hidden near K and L in Fig. 50, where are marked the two other tenons, likewiſe ſeen at G and H in Fig. 56, which are to receive the mortiſes K and L of Fig. 51. The diſtance between the tenons of the ſame ſide of a plate, and conſequently between their mortiſes, is arbitrary; as is alſo the length of the tenons, which are pierced, in order to their being fixed very tightly by pins about the twelfth part of an inch thick. Theſe two plates (Fig. 55 and 56.) when rightly placed between the other two plates, ſhould be perpendicular to them, and parallel to each other, as well as to the lateral edges of thoſe other plates, and the diſtance between them, from inſide to inſide, ſhould be four inches. The upper edges of the four plates, when they are put together, ſhould be horizontally level; by which means the bottom of the two largeſt plates will reach lower down than the ſmaller. Theſe two ſmaller plates (Fig. 55 and 56.) are ſhaped like a parallelogram two inches and a third wide, and four inches and thirteen twenty-fourths long. This

breadth

breadth anſwers exactly to the ſpace between the lines *i x* and *o s*, (Fig. 39.) and between the lines *f g* and *h i*, (Fig. 49.)

The plate (Fig. 55.) which is ſeen in perſpective in Fig. 52, has, quite acroſs its inner ſurface, a ſolid plint *x* L, which is of the ſame piece as the plate, and runs parallel to *f g*, (Fig. 52 and 55.) The bottom of this plint is flat, and its top is arched like a portion of a circle. Its thickneſs from *i* to *n* is nine twenty-fourths of an inch, and its projecture *i x*, (Fig. 52,) is ſuch that its edge *x* L meets the ſurface of the cellular cylinder, as in the profile *d* (Fig. 50.)

The uſe of this plint is to ſtrengthen the aſſemblage of the plates; for which purpoſe its ends *x* L, (Fig. 52.) ſhould join exactly to the larger plates: and it ſerves likewiſe to prevent the grains of corn from ſlipping down between the plate and the cellular cylinder.

To the top of the inſide of this plate is faſtened, by two ſcrews *a* and *p* (Fig. 52.) a plate of braſs one-twelfth of an inch thick. Its extent *a*, *p*, *d*, *b*, is a rectangle parallelogram, of which the breadth *a p*, or *d b*, is the ſame as that of the plate to which it is faſtened; ſo that its edges *a b* and *p d* lie cloſe to the inſides of the two largeſt plates (Fig. 50 and 51.) The profile of this plate is ſeen at *a l b*, (Fig. 50.) where it is inclined from *l* to *b*, in ſuch manner that the whole length of its edge *b d*, (Fig. 52.) is almoſt cloſe to the ſurface of the cylinder, directly above its axis, as in the profile *b*, (Fig. 50.) But this plate muſt not quite touch the cylinder, becauſe it would then obſtruct its motion, or at leaſt occaſion a needleſs and detrimental friction. Its uſe is to hinder the corn which fills the ſpace F, from falling down into the ſpace M, and to make it paſs only under the piece *r q* (which will ſoon be deſcribed) to drop from thence into three pipes, which begin near *e*, as will be ſeen hereafter.

The plate Fig. 56, (ſeen in perſpective in Fig. 53, with ſome pieces fixed to it) has, riſing upon its inner ſurface, four, exactly ſimilar ſmall partitions, which are of a piece with the plate. Theſe four partitions *c p*, *d e*, *f g*, *h i*, (Fig. 56.) are ſeen in perſpective at *m s*, *o t*, *q v*, and *r x*, in Fig. 53. The top *r x* of all theſe partitions is rounded like the quarter part of a circle, and the bottom *x v* is flat, and at the ſame height as the axis of the cylinder, as may be ſeen in the profile *e* of one of theſe partitions (Fig. 50.) The two outer partitions *c p* and *h i*, (Fig. 56.) are at the edges of the plate, and the two others *d e*, *f g*, divide the ſpace between *c* and *h* into three equal parts. Theſe partitions are about a twelfth part of an inch in thickneſs, and their rounded part terminates in an edge, that the grains which may chance to fall upon it may not lodge there. The height *u r*, (Fig. 53.) or *i h*, (Fig. 56.) of all theſe partitions, is nine twenty-fourths of an inch. The lower ends *s w*, *t æ*, *v a*, *x u*, (Fig. 53.) of all theſe partitions, are in a plane perpendicular to the plate, and parallel to the edges *b a*, *q r*, of this plate (Fig. 56.)

This plate has alſo upon its outer ſurface a ſmall cylinder, which is ſeen in profile at K, (Fig. 50.) in front at A, (Fig. 49.) and in perſpective A, (Fig. 49.) and B, (Fig. 1, Plate X.) Its whole length is two-thirds of an inch, and its diameter is half an inch, excepting its ſhoulder at the plate, which is a little more. This cylinder is pierced lengthways with a female ſcrew, which goes through the plate perpendicularly to its ſurface, and through which paſſes a ſcrew C *q*, (Fig. 50.) five twenty-fourths of an inch in diameter, of which the end is ſeen at *q*, and the head at C. This head is alſo ſeen at B, (Fig. 1. Plate X.) The hole is ſeen at *k* (Fig. 56.) in the inner ſurface of the plate. The center of this hole *k* is in the middle of the breadth of the plate, and at the diſtance of five twenty-fourths of an inch from its edge *a b*. This fixes the place of the ſcrew and of its cylinder; the only uſe of which laſt is, by its length, to give the greater ſtability and firmneſs to the ſcrew, which keeps the bin at a greater or leſs diſtance from the cellular cylinder.

Of the Bin and its Valves, Plate XIII.

The bin, which has ſix valves, is ſeen in profile at *q n*, (Fig. 50.) The outſide of this bin is ſeen in perſpective at *g h n*, (Fig. 53.) with the ends of the valves *a*, *b*, *c*, *d*, *e*, *f*, ſeparated from each other by partitions. It is ſuſpended in the box by the axis or ſcrew before-mentioned (Fig. 50 and 51.) which goes in at the hole *n* in the end (Fig. 51.) of the box, then paſſes through the hole *n* of the bin (Fig. 50 and 53.) runs quite through the length of the bin, and ſcrews into the female ſcrew in the plate (Fig. 50.) which, as was ſaid before, is directly oppoſite to the hole *n* in the plate (Fig. 51.) The head of this ſcrew, at *n* (Fig. 51.) lies even with the outer ſurface of this plate.

Fig. 57 repreſents in perſpective the bin alone and its partitions, all made of one piece, or plate of braſs. Fig. 58 repreſents geometrically the fore-part of the bin, which is here turned towards the ſeedſman. Fig. 60 repreſents its back. Fig. 62 its bottom. Fig. 59 one of its utmoſt ſides, or largeſt partitions, both of which are equal and alike. And Fig. 61 the ſide or profile of one of the ſmaller partitions, which are all equal and like to each other.

The whole length of the bin from outſide to outſide, that is to ſay, from *a* to *c*, and from *b* to *d*, (Fig. 58.) or from *e* to *f*, (Fig. 60.) is the ſame as the breadth of the inſide of the box, or of the ſpace between the lines *i x* and *o s*, (Fig. 39.) or *f g* and *h i*, (Fig. 49.) The bottom of the bin is a parallelogram *i*, *k*, *d*, *b*, (Fig. 58.) or *a*, *b*, *d*, *c*, (Fig. 60.) eleven twenty-fourths of an inch wide at *a c* and *b d*. This bottom is of the ſame thickneſs as the largeſt partitions or ſides *a b*, *c d*, (Fig. 58.) and the five ſmaller partitions; that is to ſay, three twenty-fourths of an inch. Theſe partitions, both great and ſmall, are at equal diſtances from each other, and all their ſides are perpendicular to the bottom of the bin.

The whole length of the two largeſt partitions, (Fig. 59.) from *b*, to the pricked line *g d*, which is perpendicular to *a b*, is one inch and ſeventeen twenty-fourths. Their breadth at *a i* and *b c* is five-ninths of an inch. The line *c m*, parallel to *b a*, is eleven twenty-fourths of an inch long. The notch *l m* is one-twelfth of an inch deep. The angle *a*, *b*, *c*, is of eighty-five degrees. The perpendicular diſtance from the center of the hole *s*, to the line *g d*, is a quarter of an inch; and the perpendicular diſtance from the ſame center to the line *a b*, is five-twelfths of an inch. The diameter of this hole is a full twelfth of an inch. The perpendicular diſtance from the center of the hole *r*, to the line *g d*, is very near, but not quite, one-ſixth part of an inch; and the perpendicular diſtance from this ſame center to the line

a b, is five twenty-fourths of an inch. The diameter of this hole is one-ſixth of an inch. Theſe two main partitions, *a b* and *c d*, (Fig. 58.) which have now been deſcribed in the account of Fig. 59, are exactly alike, and pierced in the ſame manner; ſo that if they could be laid flat together, inſide to inſide, their dimenſions and holes would tally perfectly.

It is through the hole *r*, (Fig. 59.) that the ſcrew or axis is paſſed which keeps the bin ſuſpended to the plates, and which was mentioned before. Theſe two holes *r r* are ſeen in Fig. 57, where their axis is indicated by two pricked lines. And it is through the hole *s*, (Fig. 59.) that the ſcrew or axis is paſſed which goes through the valves, next to be ſpoken of, and by which they are ſuſpended in the bin. Theſe two holes *s s* are ſeen in Fig. 57, with their axis, which is indicated by two pricked lines.

Fig 61 repreſents the profile of the ſmall partitions. Its total height from *a b* to *c d*, is equal to the breadth *d b* of the bottom (Fig. 60.) as is ſhewn in Fig. 58. The ſhape and ſize of theſe ſmall partitions is exactly like, and equal to that part of Fig. 59, which is included between the lines *e*, *f*, *b*, *c*; ſo that their edges would tally in all reſpects, if they were laid one upon the other. The line *c d*, (Fig. 61.) is perpendicular to *c a*.

The edge *m c*, (Fig. 59.) is a bevil, ſloped towards the inſide of the bin, as at *e f*, (Fig. 57.) and *a d*, (Fig. 62.) The like edge *z b*, (Fig. 57.) and *b f*, (Fig. 62.) is ſloped in the ſame manner. All the ſimilar edges *e b*, (Fig. 61.) of the ſmall partitions, which are included between the lines *e f* and *b d*, (Fig. 58.) are bevils on each ſide, and form as many acute edges, as is ſeen in Fig. 62, between the lines *a b* and *d f*. The diſtance between the lines *a b* and *g h*, is five-ninths of an inch.

Fig. 58 is repeated in Fig. 64, with only the addition of the ſix ſprings *a b*, *c d*, *e f*, *g h*, *i k*, *l m*, each of which is faſtened by a ſmall ſcrew, *a*, *c*, *e*, *g*, *i*, *l*, at one of their ends, next to the bottom of the bin, and in the middle of the interval between two partitions. The breadth of theſe ſprings is nearly equal to two-thirds of this interval, and their thickneſs is the ſame as that of a common ſpring of a watch, which is the ſtuff they are made of. Fig. 63 exhibits a front view of one of theſe ſprings. Their length and bending, when in a ſtate of reſt, is repreſented in the profile *e d*, (Fig. 65.) *b a*, (Fig. 66.) ſhews the profile of theſe ſprings in a ſtate of contraction.

Fig. 64 is repreſented in Fig. 67, with only the addition of the ſix valves *c d*, *e f*, *g h*, *i k*, *l m*, *n o*, ſeen in profile in Fig. 65 and 66. Each of theſe ſix valves is, at moſt, one-twelfth of an inch thick, and their total length, *a b*, (Fig. 65.) is one inch and thirteen twenty-fourths. The ſix valves, put together, weigh twenty penny-weights, or five-ſixths of an ounce. When put in their proper places (Fig. 67.) each of them covers one of the before-mentioned ſprings. The breadth of each of them is equal to the whole width of the interval between two partitions, between which they muſt only be able to move. They are all faſtened to the ſame axis *a b*, which, as was ſaid before, paſſes through the holes *s s*, (Fig. 57 and 59.) The diameter of this axis is a full twelfth part of an inch. One of its ends ſcrews at *a*, (Fig. 67.) into one of the aforeſaid holes *s*, and the other end, which has a flat head, is buried at *b*, in the other hole *s*; for which purpoſe the outſide of the plate is pared away a little, around this hole. One of theſe holes is ſeen at *p*, in Fig. 50 and 53. The valves are laid flat in Fig. 67, with their ſprings contracted, as in the profile (Fig. 66.) When the ſprings are at liberty, they puſh the valves out of the partitions, as far as is repreſented in the profile (Fig. 65.) But they are kept within partitions, by a cover *a b*, (Fig. 69.) which is put into the notch *f m*, (Fig. 59.) and *e d*, (Fig. 61;) and, in ſhort, into all the notches, which are upon a level with each other, from *i e* to *f k*, (Fig. 58.)

Fig. 67 is repeated in Fig. 69, with only the addition of the cover, which is three quarters of an inch wide, as long as the whole breadth of the bin, and not quite a twelfth part of an inch thick. It is faſtened by two ſcrews *a* and *b*, which go into the upper edge of the large partitions, as appears in the profile (Fig. 66 and 70.) Fig. 70 repreſents one of the large partitions of the bin, with the end *c d* of its cover, and the head of one of the ſcrews which faſten it. Fig. 66 repreſents the profile of one of the ſmall partitions of a valve *e f*, of its ſpring *a b*, and of the cover *d e*. This figure ſhews alſo, that the end of the valve cloſes with the loweſt edge of the partition; as may be ſeen more diſtinctly at *d o*, (Fig. 67 and 69.)

Fig. 68 repreſents the back of theſe ſix valves faſtened to their axis.

The end of each valve, *d*, *f*, *h*, *k*, *m*, *o*, (Fig. 67.) is bent a little outward, as in Fig. 71, which is only a repetition of Fig. 62, with the addition of the ſprings of the valves, and their cover.

The whole bin, furniſhed with the ſix valves and their axis, the ſix ſprings and their ſcrews, and the cover and its two ſcrews, but not the axis or ſcrew which ſuſpends the bin in the box, weighs four ounces and a half.

The bin thus completed, and ſuſpended in the box, as was ſaid before in ſpeaking of Fig. 50 and 53, is again covered by a thin plate of braſs repreſented in perſpective at *i*, A, *k*, N, P, (Fig. 53.) and of which the profile is likewiſe ſeen at *i*, A, *s*, *k*, (Fig. 50.) This plate is bent at A P, (Fig. 53.) in ſuch manner that its bended part turns inward, over the upper edge of the front of the braſs-box; and its edge, which is ſeen in profile at A *i*, (Fig. 50 and 53.) and fully at *e n*, (Fig. 48 and 49.) is faſtened to the upper part of the outer ſurface of this plate of the box, by two ſcrews *e* and *n*, which go into the holes *l* and *m*, in Fig. 56. This plate, from its bending A P, (Fig. 53.) projects over into the box, inclining down to the bin, which it covers as low as N *k*, where the cover of the bin before-mentioned ends. This plate performs the office of a ſpring, and ſhould therefore be ſcrewed on very tight. It preſſes the bin againſt the end *q* of the ſcrew *q* C, (Fig. 50.) The breadth A P and *k* N of this plate, (Fig. 53.) is the ſame as the breadth of the inſide of the box; ſo that its two edges, A *k* and P N, lie cloſe to the inner ſurfaces of the two large plates, (Fig. 50 and 51.) which form the ends of the box.

Of the three Pipes of the Seed-Box, Plate XII. *and* XIII.

Fig. 72 repreſents a perſpective view of the three pipes, which are ſeen partly at B, D, E, Fig. 48 and 49,

49, Plate XII. and at *a b*, Fig. 1, Plate X. They are made of plates of braſs, about a twelfth part of an inch thick, and are ſeparated from each other only by a ſimple partition. Their front is ſeen in perſpective, and on the right-hand ſide of the drill, in Fig. 72. Their back is ſhewn in perſpective, and on the right-hand ſide of the drill, in Fig. 53. Their front is repreſented geometrically in Fig. 49 and 73; and their back in Fig. 75. Fig. 74 repreſents geometrically, the ſide or profile of the middle pipe, which is inclined with the piece that faſtens it to the plate. The profile of the pipes on each ſide of this is indicated by pricked lines.

Theſe three pipes, (Fig. 72.) are ſet againſt the plate (Fig. 56.) in ſuch manner that the edges *a*, *b*, *c*, *d*, (Fig. 72.) are applied cloſe to it, and in the ſame order, at *i r*, *v g*, Fig. 56. The edges *g h*, *f e*, (Fig. 72.) are applied in like manner at *p q*, *s e*, (Fig. 56.) The line *b h*, (Fig. 72.) is ſet exactly even with *r q*, (Fig. 56.) By this means the anterior ſurfaces *b c k i*, and *f h l m*, of the two outer pipes, (Fig. 72.) exceed the bottom of the box, as at B D, (Fig. 48 and 49;) and the upper edges *a n*, *d o*, *e p*, *g q*, (Fig. 72.) join to the lower edges of the four partitions (Fig. 56.) at *i*, *g*, *e*, *p*, as is ſeen in perſpective in Fig. 53, at *x u*, *v a*, *t æ*, and *s w*.

Theſe three pipes, which hold together, are faſtened to the plate by means of a ſingle braſs ſcutcheon A, (Fig. 72,) which is ſeen directly in front at H, (Fig. 49.) and at A, (Fig. 73.) Its fore part and right-hand ſide are ſeen in perſpective at A in Fig. 72; and its fore part and left-hand ſide at H (Fig. 48.) Fig. 75 ſhews a full view of the back part of it at A; and the whole profile of it, on the right-hand ſide, is ſeen at N *u* B L, (Fig. 50.) and at *b d l f*, (Fig. 74.) This ſcutcheon is bent at *d* and at *m*. Its breadth is the ſame as that of the middle pipe, which is the interval between the other two, as is ſeen in Fig. 48, 49, 72, 73, 75. Its part *b d*, (Fig. 74.) is ſoldered or riveted to the lower ſurface of the middle pipe: from thence it takes an horizontal direction from *d* to *m*, and then aſcends perpendicularly from *m* to *f*. This length *m d* is one inch, and the thickneſs of the ſcutcheon, throughout, is about a ſixth part of an inch, or ſomewhat leſs. The thickneſs of the plate, Fig. 56, of which the profile is here at *q l*, Fig. 74, is exactly embraced between the extremity *r i* of the pipe, and the ſcutcheon *f l*. The bottom, *q r*, (Fig. 56.) of this plate, reſts upon the horizontal part *o l* of the ſcutcheon, (Fig. 74;) and this ſcutcheon is faſtened to the plate by a ſcrew *p g*, which goes into the hole *n*, (Fig. 56.) It is to be obſerved, that the line *r o*, (Fig. 74.) is equal to the edges *a b*, *c d*, *e f*, *g h*, (Fig. 72.) of which it expreſſes the profile; that its farther extent *o a*, (Fig. 74.) is equal to the lines *b i*, *c k*, *f l*, *h m*, (Fig. 72.) of which it expreſſes the profile; and that the line *d l*, (Fig. 74.) is in the ſame horizontal plane as the line *b h*, (Fig. 72.)

The angle *r*, *i*, *e*, (Fig. 74.) is of one hundred and twenty-ſix degrees; and the diſtance from *o* to *i* is one third of an inch. The outſide breadth of theſe three pipes, taken together, is the ſame as that of the plate; and each of them occupies a third part of that ſpace, as in Fig. 53, 56, 73 and 75. Each of them is ſquare. The length of the two outer pipes, from the line *b h*, (Fig. 72.) or from the bottom *q r* of the plate, (Fig. 65.) to the line *i m*, (Fig. 72.) or *x o*, (Fig. 56.) is one inch and a twelfth: the length of the middle pipe, (Fig. 74.) from *i*, where it joins to the plate, to its other end *e*, is four inches and five twelfths.

Theſe three pipes are faſtened to the plate, as in Fig. 53. The edges *x*, *z*, *v*, T, E, *t*, *l*, D, *s*, *y*, of their upper openings, are circular, that they may fit exactly, and ſit cloſe to the circumference of the cylinder, which is there indicated by pricked lines, and is ſhewn in Fig. 50, by the line *t v f*, which expreſſes the profile of theſe edges, againſt which the cylinder rubs lightly when it turns.

Manner of working the Seed-box, and of the Pieces which it contains, Plate XIII.

The line or edge *g h* of the ſix valves, (Fig. 53.) muſt be very near to the ſurface of the cellular cylinder, tho' not quite ſo cloſe as to occaſion a friction when the cylinder turns; and the lower end of each valve muſt anſwer to a row of cavities; ſo that the part F of the ſeed-box, (Fig. 50.) being filled with corn, and the cylinder turning from *b* to *r*, this laſt carries with it the grains that fall into the cavities which paſs under the edge of the correſponding valves: thoſe that fall from the two valves *a* and *b*, (Fig. 53.) are dropped, by the cavities, into the pipe G, in the ſpace between the pricked lines *g s* and *b t*, and are conveyed to the back of the ſhare which is on the left hand ſide of the drill; thoſe that fall from the two next valves, *c* and *d*, are dropped between the pricked lines *b t* and *d v*, into the pipe H, and are conveyed to the back of the ſhare which is in the middle of the drill: and thoſe that fall from the two laſt valves, *e* and *f*, are dropped between the pricked lines *d v* and *h x*, into the pipe M, and are conveyed to the back of the ſhare which is on the right hand ſide of the drill.

If it happens that ſeveral grains preſs together at the ſame time, at the outlet of any one of the valves, ſo as to choak it, that valve immediately gives way, lets them paſs, and is inſtantly replaced as before, by means of its ſpring which puſhes it back. No grain is ever broken by the valves: ſo that if this accident does ſometimes happen to a few, it is not during the time of actually ſowing the ſeed, but only when the drill is turned, in order to begin another bout, or when the ſeedſman, inſtead of drawing the drill forward, drags it towards himſelf, and makes the cylinder turn backward.

By looſening the ſcrew C *q*, (Fig. 50.) which is at B in Fig. 1, the bin, before preſſed againſt this ſcrew by the ſpring or plate A *s k*, (Fig. 50.) is moved farther from the cylinder, the ſpace between the cylinder and the end of the valves is increaſed, and a greater quantity of corn then paſſes at a time. By turning the ſcrew C *q* farther in, the bin is puſhed nearer to the cylinder, and fewer ſeeds are dropped.

To know exactly how much the bin ſhould, at any time, be ſet nearer to, or farther from the cylinder, there is, at one of the ſides of the bin, a ſmall ſcrew, of which the head of *m* paſſes through a circular opening M N, (Fig. 51.) in the largeſt plate of the box, where it becomes a certain guide, by means of a few equal diviſions engraved and numbered at the edge of that opening. The center of the arch of this opening is the ſame as that of the hole *n*, upon which the bin moves.

Of the Hopper, Plate XIII.

Fig. 67. repreſents in perſpective the hopper which is ſeen at A in Fig. 1, and of which the bottom covers the

the top of the ſeed-box. D, (Fig. 76.) is the front, and A the right hand end of the hopper. The boards which form the ends A and B are three quarters of an inch thick; thoſe of the ſides D and C are ſeven twelfths of an inch thick; and the thickneſs of the cover is five twelfths of an inch. The ſides and ends, which are at right angles to each other, and to the bottom, are joined together by dove-tail tenons; and the bottom is joined to the ends A and B by tenons which go into mortiſes in theſe ends, as may be ſeen on the line *b g*. The four tenons G, H, E, F, enter into the mortiſes Q, R, S, T, in Fig. 24, of which the dimenſions have been given. Thoſe dimenſions fix the length *g e*, or *k d*, of the hopper, (Fig. 76.)

Its breadth, from outſide to outſide, at *a k*, or *b g*, is ſeven inches; and its outſide depth *k g*, or *d e*, is eight inches and a half. The height of the legs of the hopper, from the line *h l*, where it reſts upon the upper ſurface of the table, to the line *b g*, which is the under ſurface of its bottom, is determined by the diſtance between the top of the ſeed-box and the top of the table: it is here eight inches and a ſixth. In the middle of the breadth of the two legs, are two openings, N and P, rounded at their top, to let through them the iron axis which bears the cellular cylinder, and keeps the ſeed-box ſteady under the hopper. Theſe two openings are ſeven inches high, and one inch and three quarters wide. The hopper is faſtened to the table by two hooks, one of which is ſeen entire at L N M, and part of the other at P Q. Each of them moves upon its rivet L, juſt above the opening of the foot, and is bent from thence to N to make room for the paſſage of the axis; after which it hooks into a ring M and Q, fixed upon the table, but not mentioned before.

Towards D is a ſquare opening, an inch and a half wide, cut immediately above the bottom, and through which the hopper may be emptied. This opening is ſhut by a ſmall plate of iron, or braſs, which turns like a latch upon a ſcrew *n*, which faſtens it at that end, whilſt the other end *r* is ſlipped down to the ſmall piece of braſs or iron *v x*, which is faſtened to the box by a ſcrew at *x*, in ſuch manner, that the pricked part of the latch, near *r*, is covered by the end *v* of this laſt ſmall piece, which is bent for that purpoſe, ſo as not to lie quite cloſe to the box, and the edge *r q* of the farther part of the latch reſts upon the edge *x* of this ſmall piece.

Of the Fore-Carriage, Plate XIV.

Fig. 77 is a perſpective view of the fore carriage without its wheels. It is ſeen with its wheels in Fig. 1. Plate X. Fig. 80 repreſents a geometrical plan of the inſide of one of the wheels of the fore-carriage, which is ſeen at *t* Fig. 1, Plate X. and Fig. 81, Plate XIV. repreſents a ſection of it. P and Q, (Fig. 77.) are the two fore-ends of the beams, to which the fore-carriage is faſtened by hooks and rings.

In Fig. 77, *a d*, and D E, are the two exactly ſimilar pieces which are ſeen at S *s* and V *r* in Fig. 1. Their length *a d*, (Fig. 77.) is two feet eight inches; their breadth, *d* A, is two inches and two thirds, and their thickneſs is two inches. They are parallel to each other, and connected by two traverſes, *g*, *h*, *f*, *l*, of which the ends are tenons pinned into mortiſes in the pieces D E, *a d*. Theſe two traverſes are omitted in Fig. 1. Plate X. in order to render that drawing the more ſimple. The length of theſe traverſes, excluſive of their tenons, is two feet, their breadth is two inches and a quarter, and their thickneſs one inch. Theſe two traverſes are perpendicular to the two other pieces. Their diſtance from each other, between the fartheſt outſide edge *g h* of the one, Fig. 77, and the fartheſt outſide edge *f l* of the other, is ſeven inches and a half. The edge *g h* is one foot ſix inches and a third diſtant from the two ends B and D.

F G is an axle-tree, of which the middle part *n s* is two inches and ſeven twelfths ſquare, and of which the upper angles are cut off as in the drawing. The ſquare ſhoulders of the two ends *s n*, from whence the ſpindles proceed, project a very little beyond the outſide of the pieces D E, and *a d*, in order that the nave of the wheels may not rub againſt theſe pieces. The ſpindles *s* G, *n* F, are eight inches and a third long, and one inch and five twelfths in diameter. This axle-tree is placed upon the pieces D E, *a d*, parallel to the traverſes *g h*, *f l*, in ſuch manner that the diſtance from the line *s n* to the ends E and A, is a foot and a half. This axle-tree is faſtened to the two pieces D E, *a d*, by two iron pins and nuts, *b q*, an inch and a ſixth ſquare, of which the ſcrew, which is ſeven twelfths of an inch in diameter, has a head an inch and a half in diameter, which lies cloſe to the under ſurface. This ſcrew is repreſented with its nut in Fig. 78. Upon this axle-tree are fixed two wooden pins, five or ſix inches long, and five tenths of an inch, or a whole inch in diameter. Theſe pins are perpendicular upon the upper ſurface of the axle-tree; the ſpace between them is four inches, and this ſpace is in the middle of the length of the axle-tree. This axle-tree is pierced perpendicularly between the two pins, to admit another pin, which will ſoon be ſpoken of.

The two wheels, which are placed at F and G, are exactly alike. Fig. 80 repreſents the inſide of one of theſe wheels, with a pully fixed round its nave, and faſtened to its ſpokes by four ſcrews, each of which goes through the pully and one of the ſpokes. This pully is ſeen in profile at *b d*, (Fig. 81.) with two of its ſcrews.

The total diameter, *g h*, of each wheel, excluſive of its iron hoop, is two feet and a half; that of the nave *p q* is four inches and one ſixth; that of the pully *b d* is one foot two inches and a ſixth; the thickneſs of the pully is an inch and one third; its groove, which is cut down ſquare, is two thirds of an inch wide, and two thirds or three quarters of an inch deep. The length *p r*, or *q s* of the nave, is ſix inches; the thickneſs of the wheel at *i n* is an inch and two thirds, and at *i h* two inches and a quarter. Of the four hooks R, H, T, K, (Fig. 77.) which ſerve, by means of two rings, to faſten the fore-carriage to the ends of the beams P Q, the two, H and K, are faſtened in the uſual way, by nailing them, at their flat end, upon the two pieces of the fore-carriage: but the other two, R and T, are ſhaped like a carpenter's ſquare, of which one end is ſcrewed upon the beam, in order to facilitate the putting on or taking off the ring. At T, this hook is placed in its proper ſituation for holding the ring: at R, it is turned the other way, that the ring may be taken off eaſily.

Of the Pieces which ſupport the Drill upon its Fore-carriage, Plate XIV.

Fig. 82 repreſents in perſpective a piece of wood which ſupports the drill upon its fore-carriage, when there is occaſion

occaſion to turn it in ſowing. This piece may be called the pole. It is ſeen at *x d* in Fig. 1, Plate X. Its end A, (Fig. 82.) enters into the two bridles or belts *g r h* and *a c b*, (Fig. 26,) which have been ſpoken of before, and of which one is ſeen near *d* in Fig. 1. Its other end *q r*, (Fig. 82.) reſts upon the axle-tree (Fig. 77.) between the two pins, as is expreſſed by pricked lines in Fig. 82, and as may be ſeen at *x* in Fig. 1.

The breadth *q r*, (Fig. 82.) of the lower ſurface of this piece is an inch and a quarter, throughout its whole length, to its end A; and its thickneſs throughout its whole length *q s* is an inch and a half. Its upper angles are taken off, from the end *q r* to *s*; but from *s* to A, this piece is ſhaped like the two bridles or belts into which it is to enter.

Its length from *q* to *s* is one foot ſeven inches and five-ſixths; and from *s* to *t*, it is two inches and ſeven-twelfths. At *t*, the thickneſs of a quarter of an inch is taken off from its under ſurface, as at *t v*; and from *v* to A, its length is five inches and five-twelfths. It is the length *s* A, that goes into the two belts or bridles *g r h*, and *a c b*, (Fig. 26, Plate XI.) and the notch or ſhoulder *t* is made in order to inſert a wedge whenever it is neceſſary to make the end *q r*, (Fig. 82.) reſt upon the middle of the axle-tree, in order to convey the drill the more eaſily to any diſtant part, without putting it upon its hind-carriage. This wedge ſaves the ſeedſman the trouble of holding up the handles of the drill ſo high as he would otherwiſe be obliged to do, to make the end *q r* of this piece (Fig. 82.) reſt upon the axle-tree. It is by the help of this piece, that the ſeedſman, when he comes to the end of each bout of the drill, is enabled very eaſily to turn it in order to begin another, by lifting the drill up by its handles; for as the end of this piece reſts upon the middle of the axle-tree, he makes the drill follow the fore-carriage which is drawn by a horſe; and as the diſtance, in this caſe, is but five or ſix feet, there is no occaſion for his making uſe of the wedge. By this means the drill is turned conveniently, and without any loſs of time.

The line A *v*, *t s*, are even; but *q s* is inclined at *t s*, and makes with it an angle *t s q* of 166 degrees. *s a* and *g n* are two ſquare pins, faſtened by tenons into the middle of the breadth of the under ſurface *r q s*, perpendicularly to the lower ſurface *t s*. The pin *s a* is placed near the bending *s*, and the diſtance between the edges or lines *s a* and *g n*, is fourteen inches and two thirds. The breadth *a o* and *n p* of theſe pins, is an inch and a quarter; their thickneſs is two thirds of an inch; the length of *s a* is three inches and a half, and that of *g n* five inches. This pin *g n* is reſted againſt the axle-tree F G of Fig. 77, and the other, *s a*, (Fig. 82.) is placed near the table of the drill. The uſe of theſe two pins is only to hinder this piece of wood from ſlipping out of the two belts before deſcribed.

Fig. 83 repreſents in perſpective the piece of wood which ſupports the drill upon its fore-carriage, when it is placed upon its hind-carriage, in order to be removed from one place to another. This piece neither is, nor can be, ſeen in Fig. 1, which repreſents the drill in the ſtate of actual ſowing, and without its hind-carriage. The end A, (Fig. 83.) goes into the belts *e f*, *g h*, (Fig. 21.) before deſcribed, like which it is ſhaped; and the end B, (Fig. 83.) reſts upon the axle-tree, (Fig. 77.) between the two pins. This part of the axle-tree is covered before and beneath by a ſlip or hook of iron, B E C, (Fig. 83.) which is nailed under the end of the piece A B, as in Fig. 84. The axle-tree, the bar, and its hook, are traverſed by an iron pin, D E, (Fig. 83.) and *d e* (Fig. 84.) which paſſes through the hole in the axle-tree, between the two pins, (Fig. 77.) The length of this piece, A B, (Fig. 83.) is three feet and four inches: its breadth is two inches and a half, and its thickneſs is one inch and a third. The pin F G, which is ſuſpended here, is put into the ring or bridle L, (Fig. 22.) and goes through the hole immediately underneath it.

Of the Hind-Carriage.

This hind-carriage is ſo ſimple that it would be needleſs to give a drawing of it. It conſiſts only of two common wheels, unſhod with iron, two feet eight or nine inches in diameter, ſet upon a very ſimple axle-tree, in the upper ſurface of which are two holes, into which are put the two pins before-mentioned, which are under the beams of the drill. One of them is ſeen at *f h*, (Fig. 3.) and likewiſe at Δ, (Fig. 1.) Plate X.

It is neceſſary to fix, by proper marks, the reſpective places of the ſeveral ſcrews and mortiſes of the whole machine, in order that when it is taken to pieces and put together again, none of theſe pieces may be miſplaced, or any of the helixes (or ſpiral lines) which the flat-headed ſcrews have formed in the wood, be ſpoiled.

It is better to make the teeth of the harrow bend a little more than thoſe before deſcribed, and repreſented in Fig. 5, Plate X. They ſhould bend ſo that the point *e* of the tooth may project about four inches beyond the pricked line *f*.

Figures 85 *and* 86, *Plate* XIV. *compared with Figures* 2 *and* 31, *Plate* X. *and* XII.

The mortiſe A, in Fig. 85, is the ſame as that which is marked Q in Fig. 2. But the end of each beam ſhould be made about two inches wider on the inſide, and a ſecond mortiſe B, (Fig. 85.) ſhould be cut through it, ſimilar and parallel to the former, and at the diſtance of five-ſixths of an inch, or an inch, from it, that the ſhare may be faſtened in the one or the other, according as it may be found proper to place the two fore-ſhares nearer to, or farther from each other, in order to ſow the rows cloſer than they would be by the ſituation of the mortiſes Q and R, (Fig. 2.) but then the pipes which anſwer to the back of theſe two ſhares ſhould be faſtened in the manner which will be explained hereafter.

The middle piece K L, (Fig. 2.) ſhould project beyond the table, from C to D, (Fig. 85.) about nine inches or a foot, and the belt or bridle L, (Fig. 2.) ſhould be ſuppreſſed. This ſame piece ſhould have, in its part E F, (Fig. 85.) nearly the ſame breadth as the end of the beams H, I; and two mortiſes, E F, inſtead of one, in which the ſhare, thicker than was ſaid before in its upper part, is to be faſtened by two tenons and a key. The pipe which terminates behind this ſhare, inſtead of paſſing ſideways, as in Fig. 31, will go ſtraiter and more eaſily through the hole G, (Fig. 85.) which is ſeen at K, (Fig. 86.) and from thence through the thickneſs of the ſhare, which will be pierced for this purpoſe from K to G. The ſole of this ſhare, from

this

this hole to its bottom, will be of the ſame thickneſs as was mentioned before.

Figures 87 *and* 88, *Plate* XIV. *compared with Figures* 29 *and* 30, *Plate* XI.

The upper openings, *f d*, *h o*, (Fig. 29.) of the two foremoſt pipes ſhould be joined by a good hinge A, (Fig. 87.) well ſoldered to them, and of which the pin, ending with a ring at one end, may eaſily be taken out. By means of this hinge, theſe two pipes may be ſet cloſer together, or farther aſunder, like the legs of a compaſs, and be fitted to the different ſituations of their ſhares. The faſtening of the lower end of theſe pipes will be nearly the ſame as was deſcribed in Fig. 30; with this difference, that inſtead of bending the ſquare *k i g* of that figure only at *i*, upon its upper ſurface, and making its part *k i* run lengthways of the beam E F; here, (Fig. 88.) is twiſted as it were in its bending, in order that the part *s n* may lie acroſs this beam, and lengthways of the table. In this caſe, if the ſhare A be put into the mortiſe B, the parts *s n* muſt be ſlipped farther, till the hole *s* can be faſtened at *n*, by the thumb-ſcrew which is at *n*: and as this part, being held only by a ſingle ſcrew, might be apt to looſen and jog, a piece or ſlip of iron, *a v*, is permanently fixed at its edge, ſo as to keep it tight in either of its ſituations. The ſcrew *n* faſtens in a nut ſunk into the upper ſurface of the beam, where this nut is permanently fixed, and covered by the table. There ſhould likewiſe be two holes in the other part of the ſquare, towards *q*, to ſerve for the two different ſituations of the ſhare. The pipes of the ſhares are more eaſily made round, as is here repreſented, than ſquare, as was directed before.

Figure 89, *Plate* XIV. *compared with Figure* 35, *Plate* XI.

Inſtead of the ſmall groove *n*, (Fig. 35.) in the braſs cylinder, intended for introducing a little oil to that part; a more ſimple way will be to bore a perpendicular hole *p*, (Fig. 89.) through the head of the ſtandard, down to the ſpindle; and this hole may be covered by a ſmall plate A, made to turn upon a ſcrew or rivet.

Figures 90, 91, 92, 93, *and* 94, *Plate* XIV. *compared with Figures* 50 *and* 53, *Plate* XIII.

As the three pipes or funnels G, H, M, (Fig. 53.) embrace at their upper opening only a ſmall part, *f*, *t*, (Fig. 30.) of the cellular cylinder, ſome grains may chance to be loſt on the ſide where this cylinder is not covered, from *d* to *f*. To prevent this inconvenience, they may be made ſo as to embrace the whole lower ſemidiameter *d f t*, of the cylinder in the manner repreſented in Fig. 90, 91, 92, 93, 94.

The firſt funnel, which is ſeen geometrically at A, B B, (Fig. 90.) is repreſented in perſpective, and of a ſmall ſize, in Fig. 93, where its coreſponding parts are marked with the ſame letters *a*, *b b*. This is the funnel M of Fig. 53. The ſecond large funnel, of which a part appears at D, (Fig. 90.) is ſeen entire and in perſpective, in Fig. 92, where the ſame part is marked *d*. This is the funnel H of Fig. 53. Two ſcutcheons *g* and *p* are ſoldered to this funnel, and faſten it, by ſcrews, to the fore and hind inner ſurfaces of the box, at P G, (Fig. 90.) The third funnel, which does not appear in Fig. 90, and which is like the firſt, is repreſented in Fig. 91. This is the funnel G of Fig. 53. Theſe three funnels are made ſeparately, of very thin plates of braſs, bent, and well ſoldered; and are afterwards firmly rivetted to each other, ſide to ſide, as in the perſpective, (Fig. 94.) They are ſo tightly joined, that the ſcutcheons *g p*, (Fig. 92 and 93.) are alone ſufficient to hold them all in their proper places.

Figures 95 *and* 96, *Plate* XVI. *compared with Figures* 66, *Plate* XIII.

In the repreſentation of this part in Fig. 66, the valve *e f*, is actually cloſed by its ſpring *a b*, to the cover *d c*, and in this ſituation it is ſhut: but when the corn preſſes againſt this valve, and forces it into the ſituation *a b*, (Fig. 95.) a grain may jump ſo as to get between the valve and the cover, and thereby hinder the valve from cloſing again; ſo that more corn would continue to run out. To guard againſt this accident, each valve muſt have a ſmall tongue *p* immediately below the cover, and the cover muſt be bent in that place, to receive the tongue when the valves cloſe. Both of theſe are repreſented ſeparately in perſpective, in Fig. 96.

Figure 97, *Plate* XIV. *compared with Figures* 50 *and* 51, *Plate* XIII.

Inſtead of the index *m*, (Fig. 50.) and the graduated opening M N, (Fig. 51.) an eaſier and more ſimple way will be, to faſten the end A of a graduated limb or border of a circle, A B, (Fig. 97.) to the bin, in ſuch a manner that its other end B may project through a hole in the front of the braſs-box. This will mark exactly the ſituation of the bin.

Figure 98 *compared with the Figures* 82, 85, *Plate* XIV. 21, 26, *Plate* XI.

When the middle piece is lengthened, as at C D, (Fig. 85.) there is no occaſion for the ring or bridle L, (Fig. 2.) and *f k*, (Fig. 26.) or for the pieces *s a* and *g n*, (Fig. 82.) and then the pole A, of this Fig. 82, will paſs through the belt A, (Fig. 98.) and through another belt B, which laſt goes round it and the piece D. This belt is fixed by two ſcrews under the piece B D. The pin C, which penetrates into the table, will complete the fixing of this pole. The hole K, (Fig. 85.) receives the pin F G, (Fig. 83.) which goes through the two pieces C D, (Fig. 85.) and A B, (Fig. 83.)

M. de Chateauvieux's *Inſtructions concerning the Manner of uſing his* DRILL-PLOUGH.

This drill is repreſented in Fig. 1, Plate X. with all its parts put together, in a ſtate fit for working. When the thongs which encompaſs the grooves of the pullies Q P of the axis in Fig. 1, and thoſe of the forecarriage *u t*, are ſtretched properly, and the hopper is filled with corn, a horſe is to be harneſſed to the ſpring-tree bar, and an intelligent man, who can walk a good pace, ſhould guide this horſe, which ſhould be a mild, tractable creature.

"The ſeedſman will hold the handles of the drill, in order to direct it: and he will warn the guide whenever he deviates from the ſtrait line in which he ought carefully to keep. He will alſo obſerve from time to time, whether the diſtribution of the ſeed is not ſtopped by ſome unexpected accident: for he can ſee the end of the pipes through which the grain ſhould drop; beſides which the corn makes a little noiſe in paſſing through the

the pipes, and he may eaſily hear it. The ſeedſman will take particular care that the thongs do not ſlip out of the grooves of the pullies; and if they do, he will replace them inſtantly: but this accident is very rare; nor, indeed, does it hardly ever happen, unleſs the thongs are new, and have not yet been ſufficiently ſtretched. It is proper to obſerve here, that we have tried hempen ropes, and ſmall iron chains: but thongs of leather are much better than any other thing.

"Care ſhould be taken, that the ſeed-corn be free from grit, dirt, or little ſtones; for either of theſe might damage the valves of the bin. If the corn has been ſteeped in lime-water, as is the practice of ſome farmers, in hopes of preſerving their crops from ſmut, it muſt not be ſown till it is ſo dry that the grains will ſlip eaſily over one another.

"The ſeedſman will be particularly careful to repleniſh the hopper before it is quite empty.

"He will oil the ſpindles of the axis once or twice a day; obſerving that they require moſt frequent oiling when the drill works in dry ground, which ſends up a very fine duſt: and he muſt cleanſe the ſpindles and the pipes in which they turn, every morning, by rubbing off the old oil, and putting on new. He will alſo, from time to time, cleanſe the ſpindles of the axle-tree of the fore-carriage, and rub them with ſoap. If any rain happens to fall during the time of ſowing, he muſt wipe the drill very dry, as ſoon as he has got it home, and particularly about the axis, to prevent its ruſting. It is even highly proper to have a leather covering to put over the table and all the parts upon it, and likewiſe over the ſtandards, the axis, and the hopper. It is eaſy to conceive the proper cut of this covering.

"The prudent huſbandman ſhould always have with his drill, a ſmall box, containing a hammer, a pair of pincers, a turn-ſcrew, thongs, ropes, nails, irong-rings and buckles, a little bottle of oil, and other ſuch like things, in order that, if any of them ſhould be wanted in the field, he may not loſe time by being obliged to ſend home for them.

"The ſeedſman will obſerve, when he is going to ſow, not to leave the wedge *t*, (Fig. 24, Plate XI.) under the pole, in order that the end *c*, (Fig. 1, Plate X.) may not preſs upon the axle-tree of the fore-carriage. (The only uſe of the pole, at the time of ſowing, is to turn the drill when a ſecond bed is to be ſown after the firſt is finiſhed, and ſo of others. It is eaſy to conceive, that if this end of the pole ſhould make the drill reſt upon the axle-tree, it might often happen, that, by its being thereby too much ſubjected to the motions of the fore-carriage, the ſtones or clods which the wheels may meet with, would, by raiſing them higher than the general ſurface, throw the ſhares out of the ground, or at leaſt occaſion the furrows to be ſhallower in thoſe places; things which ought by all means to be avoided.

"We have repreſented but one ſpring-tree bar, in Fig. 1, becauſe we think a ſingle horſe may be uſed, without any inconvenience, when the ground is not too much loaded with wet: but if the land be too full of water, two horſes muſt be put to the drill, which, in that caſe, muſt have a double bar, the manner of ordering which is too well known to need any deſcription. Each horſe will then go in a furrow, and they will not poach the bed, as would be the caſe, in wet land, if the drill was drawn by only one horſe, whoſe ſteps are determined by the middle of the bed.

"For want of horſes, oxen may be uſed, and the ſowing may be performed equally well.

"It is proper to obſerve, that the quantity of ſeed diſtributed by the drill is exactly the ſame, whether the horſes or oxen go faſt or ſlow. If, for example, one bed is ſown in ten minutes, and twelve or fifteen minutes are employed to ſow another, of equal dimenſions, neither more or leſs ſeed will be dropped in one, than in the other; becauſe the revolutions of the cylinder, (Fig. 39.) are invariably regulated by thoſe of the wheels of the fore-carriage, whoſe circumference, be it turned quick or ſlow, will always deſcribe a line of equal length, and the cylinder turns exactly with theſe wheels. The only difference that can ariſe from the greater or leſs ſpeed of the horſe, is the gain or loſs of time: but the quantity of ſeed ſown will be conſtantly the ſame, ſo long as the drill remains ſet in the ſame manner.

"The greater or leſs goodneſs of the ſoil, its having been well or ill prepared for ſowing, its ſtate of dryneſs or humidity, and ſeveral other circumſtances which ſhould be carefully attended to, will oblige the huſbandman ſometimes to vary the quantity of ſeed. The drill is accordingly made to diſtribute more or leſs, by the means before-mentioned, of placing the bin nearer to, or farther from the cellular cylinder, by turning the ſcrew L, (Fig. 50, Plate XIII.) By ſetting the bin farther off, a greater quantity of ſeed is dropped; and by bringing it nearer, a leſs proportion is ſown. It will be eaſy to find the proper diſtance at which to fix it, in order to its giving out exactly the deſired quantity of ſeed.

"Though this method affords a pretty wide latitude, it may ſometimes not be ſufficient. This is a caſe which will very ſeldom happen, and which we have not yet met with; but if it ſhould at any time take place, the drill may eaſily be made to diſtribute ſtill more or leſs ſeed, by changing the pullies of the axis, Fig. 39, Plate XII. for others of a larger or ſmaller diameter, which will either accelerate or retard the motion of the axis, in proportion to their ſize.

"We will ſuppoſe, for example, that the pullies are but of half the diameter of thoſe before deſcribed. It is evident that theſe ſmaller pullies will make the axis turn round twice, where it turned but once with the former, and that double the quantity of ſeed will conſequently be dropped on the ſame length of ground. By the ſame rule, pullies twice as large will turn the axis but half the number of times, and but half the quantity of ſeed will of courſe be let fall, in the ſame ſpace. The proportion of the ſeed ſown may likewiſe be increaſed or diminiſhed, by a greater or leſs number of cavities in the cellular cylinder; and the changing of this cylinder it ſoon and eaſily performed: but, as was ſaid before, there will very ſeldom be any occaſion for theſe alterations.

"The furrows opened by the ſhares of the drill, and in which the ſeeds are depoſited, ſhould be of different depths, in different caſes; and this may be effected by means of the rings which faſten the drill to its fore-carriage at the hooks RH, TK, (Fig. 77, Plate XIV.) For general uſe, the diameter of about three inches, from inſide to inſide, will be ſufficient for theſe rings, and then the furrows are made about three or four inches deep. They will be opened deeper by uſing rings, about four

inches in diameter; and it is immaterial whether they are round or oval. With ſmaller rings, the furrows will be made ſhallower; and their depth may alſo be diminiſhed, by making the horſe draw with longer traces, or by uſing a lower horſe.

"If very ſhallow furrows are wanted, or only juſt the ſurface of the ground is intended to be opened, the wedge *t*, (Fig. 24,) muſt be put under the pole. In ſhort, a little practice will ſoon ſhew the huſbandman how to manage this drill in every reſpect, and make him thoroughly acquainted with all that is neceſſary to be known in regard to the diſtribution and proper covering of the ſeed, which laſt part is perfectly well performed by the teeth of the annexed harrow.

"If any thing ſhould ſtill ſeem obſcure to thoſe who have read attentively, and ſtudied the deſcription of each part of this drill, let them but ſet actually to work, and their ideas of it will ſoon be perfectly clear. Each part, taken ſeparately, may be made with great eaſe: their ſizes, ſhapes, and proportions, are pointed out in ſuch manner, that no workman of common underſtanding can miſtake; and when the parts are conſtructed, there can be no difficulty in putting them together, if the foregoing directions are but obſerved."

"*Deſcription of a Harneſs, to yoke Oxen one before another,*" *Plate* XIV.

"The utility of being able to put oxen to this drill, in ſuch manner as to make them go one before another in the furrow, without treading upon the places which are to receive the ſeed, firſt put me upon contriving a harneſs proper for theſe cattle: for I was not ſatisfied with thoſe I had ſeen in different countries. Two of my teams of oxen, harneſſed in my new manner, have worked the whole year; ſeveral perſons have adopted the method; and I am more and more pleaſed with it. This harneſs is very ſimple, and very light, and does not ſubject the oxen to any irkſome confinement.

"Fig. 99 and 100, repreſent the whole of this harneſs, that is to ſay, its plan and a view of it. Fig. 99 ſhews it to be compoſed of a yoke A, which the ox bears upon his head, and which is there faſtened to his horns by long thongs. The reſt of the harneſs is of leather. The piece B, is the principal part, and that by which the ox is to draw. It reſts againſt his neck, a little below the withers, and ſits extremely cloſe to the neck when the ox draws. If it is made of double leather, there is no occaſion for the piece of leather D, which ſerves only to ſtrengthen it when it is ſingle. The thong C faſtens in the buckle QR, which is fixed to the yoke by another thong. The uſe of theſe is to hinder the large piece of leather B, from riſing above the withers, when the ox toſſes his head, or raiſes his neck. Care ſhould be taken not to ſtretch the thong C too much, for the ox muſt not draw by it.

"The thong EE, with their buckles to lengthen or ſhorten them ſerve to make the oxen draw by the yoke, by putting them through the large iron buckles FF, and the leather buckles GG, which muſt be nailed to the yoke. The length of theſe thongs is ſuited to the purpoſe for which they are intended.

"My traces are made of ropes, and I find them convenient. At one end of them is part of a leathern trace, about fifteen inches long, like the end of the harneſs of a coach horſe. This end is put through the large buckles FF, where it is faſtened by the tongue *a a*: ſo that the trace may eaſily be ſhortened or lengthened."

DRILL-RAKE, an inſtrument invented by M. Vanduffel, for drilling peaſe, &c.

This inſtrument, which is chiefly calculated for light grounds, in ſmall incloſures, not exceeding four or five acres. It is a ſort of ſtrong plough rake, with four large teeth at *a a*, *b b*, (Plate XV. Fig. 1,) a little incurvated, as repreſented in the figure. The diſtance from *a* to *a*, and *b* to *b*, is nine inches. The ſpace, or interval, between the two inner teeth, *a* and *b*, is three feet ſix inches, which is ſufficient room for the cultivator or hoe-plough to move in, if conducted with care, before the peaſe have branched much. To the piece of timber *c c*, forming the head of the rake, are fixed the handles *d*, and the beam *e*, to which the horſe is faſtened.

It is evident, that when this inſtrument is drawn over a piece of land made thoroughly fine, and the man who holds it bears upon the handles more or leſs, according to his diſcretion, four channels or ſmall furrows, *f*, *g*, *h*, *i*, will be formed; that the diſtance between the furrows *h i*, and *f g*, will be nine inches: and that the interval *e*, or ſpace contained between the furrows *g*, *h*, will be three feet and a half. It is alſo evident, that theſe diſtances may be preſerved with great truth, provided the teeth *a*, *a*, return (when the ploughman comes back, after having ploughed one turn, or a bout, as they call it) in two of the channels formed before, marked *b*, *b*; ſo that though he cuts four drills at the firſt bout, yet, in effect, he only forms two drills each turn, becauſe there are always two drills to be paſſed over twice, or reploughed, being, in fact, not much more than guides, or marks of direction. Yet even this ſmall work of ſupererogation repays itſelf, becauſe its makes the drills more open, diſtinct, and clear.

If the firſt four channels, formed at one motion by this inſtrument, are ſtreight and true, all the lines in the field will partake of the ſame regularity. It will therefore be proper to mark out this firſt trace of the drill-rake by exact meaſurement, fixing into the ground, at every diſtance of ten feet, little flat ſticks, labelled with paper; which being finiſhed, the reſt may be left to the ploughman.

When the ground-plot of an acre is thus formed into drills (which may be completed in four hours, by one ploughman, a horſe, and a boy to lead the horſe) you muſt ſend two or three women and children into the field, in order to ſprain the peaſe, or ſcatter them by a ſingle motion of the hand, at a certain diſtance one from another, into the channels. Uſe no harrow, which will be apt to draw the ſeeds out of the lines; but cover them with the flat part of the head of a hand-rake, and preſs them down gently.

The great excellence of this drill-rake conſiſts in its ſimplicity; for after the meaſurement of the parts is once laid down, the meaneſt carpenter and ſmith in England can either make or repair it; and if the firſt four lines formed by it are true, the reſt of the lines or rows muſt be geometrically exact, which is an elegance none can feel, but ſuch as take delight in correct huſbandry. *Eſſays in Huſbandry*, *Eſſay* II. *page* 212.

DRONE, the male bee, one that makes no honey. *See the article* BEES.

DROPSY, a diſeaſe incident to horſes, and generally called the water-farcy. *See* WATER-FARCY.

DROPWORT, the name of a perennial weed common in paſture lands, having winged leaves; the diviſions

ſions of which are all regular, and ſharply indented about the edges. The flowers are white, growing in a bunch like an umbel. Its roots are very remarkable, conſiſting of a bunch of knobs hanging upon threads: from whence it has the name of filipendula, and dropwort. The flowers have an agreeable ſmell.

DROUGHT, dry weather, want of rain. It alſo ſignifies thirſt, or want of drink.

DUB, a pool, or pond of water.

DUCK, the name of a well-known fowl, very neceſſary for the huſbandman's yard, as they require no charge in keeping; for they live on loſt corn, ſnails, &c. for which reaſon they are very proper for gardens. Once in the year they lay a great number of eggs, eſpecially a ſort of duck which turns up its bill more than the common kind. When they ſit they require no attendance except they have a little barley or offal corn near them, that they may not ſtraggle far from their neſts to chill their eggs. They are reckoned to be better hatched under a hen than a duck; becauſe while they are young the hen will not lead them ſo often into the water. Some reckon it very proper to cut off the feathers from their rumps; becauſe when their tails are wet, it often occaſions their drowning. As to the fattening of them, you may do it in three weeks time, by giving them any kind of corn or grain, and plenty of water. Ground malt, wet either with milk or water, is beſt. *Mortimer's Huſbandry, vol.* I. *page* 257.

DUN, a colour partaking of brown and black.

DUNG, the excrements of animals, putrified vegetables, &c. uſed in improving land.

Dungs are intended either to repair the decay of exhauſted worn-out lands, or to cure the defects of other ſoils, which are as various in their qualities, as the dungs uſed to meliorate or reſtore them. Some lands are too cold, moiſt, and heavy; whilſt others are too light and dry. To anſwer this, ſome dungs are hot and light, as that of horſes, ſheep, pigeons, &c. Others again are fat and cooling, as that of oxen, cows, hogs, &c. And as the remedies which are uſed muſt be contrary to the diſtempers they are to cure, ſo the dung of oxen, cows, and hogs, ſhould be applied to lean, dry, light earths, to make them fatter and cloſer; and hot and dry dungs to cold, moiſt, and heavy lands.

Dung has two peculiar properties. The one is to fatten the earth, and render it more fruitful; and the other, to produce a certain ſenſible heat, capable of cauſing ſome conſiderable effect; which laſt is ſeldom found but in the dung of horſes and mules, while it is newly made, and a little moiſt.

Horſe-dung, the leaſt fat of any, is the moſt fiery, if taken freſh as it falls, and the moſt apt to excite a ſudden fermentation; for which reaſon it is then fit only for the hot-bed. When this heat is paſt, it may be ſpread on fields where we would have a rank graſs to ſpring: but it ſhould not by any means be admitted into the garden, or where we would wiſh to have good roots, unleſs the ground be very ſtiff, cold, or wet, and then too it ſhould be well rotted, leſt, inſtead of correcting the ſoil, it leaves couch, and other pernicious weeds, worſe than the diſeaſe itſelf; the ſeeds of hay, and of other plants, which the horſes eat, coming oftentimes entire from them: for thoſe vegetables which cattle chiefly eat commonly ſpring up from their dung; as long knot graſs from this beaſt; ſhort, clean, and ſweet paſture from ſheep and cows; the ſow-thiſtle from ſwine. Ground mucked with horſe-dung is always the moſt infected of any; and if it be not perfectly conſumed, it makes your roots grow forked, fills them with worms, and gives them an unpleaſing reliſh: but if laid on at the beginning of winter, and turned in at ſpring, it ſucceeds ſometimes with pulſe.

Horſe-dung is greatly improved by being mixed with its oppoſite, cow-dung, which is cold and fat; and this mixture is conſiderably meliorated if mixed with a proper earth, with mud, or with aſhes and urine. Cow-dung alone is the worſt of all dungs to endure wet, becauſe it is the moſt eaſily diſſolved. But either of theſe dungs, either ſingly, or mixed as above, ſhould not be uſed till it is old; nor ſhould it be laid abroad expoſed to the ſun and wind, as is the practice of ſeveral injudicious farmers, who let it lie ſpread on their field-lands during three or four of the ſummer months, till the ſun and air have exhauſted all its virtue: whereas, if it be laid in heaps, mixed with earth, and left in that ſtate till it be rotten, it will be the ſooner brought to a proper temper, will produce a ſweeter graſs when laid on paſture grounds, and will go much farther than in the common way when ſpread before the plough for corn, of which it will then greatly promote the growth.

Mr. Miller ſays he has frequently ſeen new horſe-dung buried as it came from the ſtable, in very cold, moiſt land, and always obſerved that the crops have ſucceeded better, than where the ground was dreſſed with very rotten dung.

Sheeps-dung and deers-dung are nearly of the ſame quality, and are generally eſteemed the beſt of all dungs for cold clays. Some recommend beating them into powder, and ſpreading them very thin over autumn or ſpring crops, about four or five buſhels to an acre, in the ſame manner as aſhes, malt-duſt, &c. are ſtrewed. But this light dreſſing does not laſt long. The moſt common way of conveying it upon the land is, by folding of the ſheep themſelves upon it, by which means their urine is ſaved as well as their dung, which ought to be turned in with the plough as ſoon as poſſible, that it may not lie expoſed to the heat of the ſun. In Northamptonſhire, they think it beſt to fold ſheep after July, and to fold them the lateſt upon dry land. In ſome parts of France, where they likewiſe fold their cows and oxen, the place of folding is changed twice every night. In Flanders, they houſe their ſheep at night with places ſpread with clean ſand, about five or ſix inches thick, which, being laid on freſh every night, is cleared out once a week. This mixture of ſand and dung makes an excellent dreſſing for ſtrong land; for the dung and urine of the ſheep is a very rich manure. M. Quintinie thinks it the greateſt promoter of fruitfulneſs in all ſorts of ground. This method of folding ſheep in a covered fold, and of mixing their dung with earth, ſand, &c. according to the nature of the ſoil it is intended for, is likewiſe, very properly, recommended by Mr. Mortimer; who adds, that he has known vaſt crops of rye upon barren lands that have been old warrens, well dunged by rabbits; and large oak and aſh upon the ſame, though the ſoil was very ſhallow.

Next to ſheeps-dung, the preference is generally given to that of ſwine, one load of which will go as far as two loads of other dung. The laying it on too thick

may perhaps have occaſioned the old miſtaken notion of its breeding more weeds than any other dung: for all dungs will make weeds ſhoot up; whether they contain within themſelves ſeeds of thoſe plants, not ſo thoroughly digeſted by the animal as to be deprived of their vegetative power, as may ſometimes be the caſe, or by the additional fertility which they communicate to the earth. This dung is beſt when carried from the ſtye directly to the field, where it is a rich manure both for corn and graſs, eſpecially the latter, and for almoſt any ſort of land. Hot ſands and gravel are particularly benefited by it; and it is reckoned a very great fertilizer of fruit-trees. Many good huſbandmen prefer this dung before moſt ordinary ſorts of manure, and to take great care not only to have their hog-yards well paled and paved with pebble, or other ſtones, or with chalk, which is much the beſt; but alſo to increaſe the quantity of the dung as much as they can, by throwing into the ſtye all the ſtraw, fruit, roots, beans, plants, weeds, &c. which are the refuſe of the garden, with the offals of the kitchen, and every kind of traſh; all which is not only very good for the hogs themſelves, but increaſes their dung to ſuch a degree, that ten or twelve ſwine have yielded ſixty or eighty loads of excellent manure in a year. Some notable farmers will make their hog-yard produce them an annual profit of twenty or thirty pounds. Mr. Worlidge thinks this the beſt of dungs to prevent or cure the canker in trees; and Mr. Mortimer eſteems it beſt for manure, when mixed with horſe-dung; for which reaſon he adviſes placing the hog-ſty as near the horſe-dunghill as can conveniently be. The farmers in Staffordſhire frequently ſow on poor light ſhallow land, a ſmall white pea, which they never reap, but turn in as many hogs as they think the crop will fatten, and let them lie upon it day and night. The dung and urine of theſe animals enriches the land ſo much, that it ſoon acquires a thick ſward, and continues to be good grazing ground for ſeveral years.

In this light, of reaping a double advantage from the manuring of land, the author of the new Syſtem of Agriculture adviſes huſbandmen to ſow ten or fifteen acres of their ground with turnip-ſeed, a little before they ſow clover, which he thinks, is beſt done in September: then, towards the beginning of March, to take the beſt opportunity to buy three hundred ſows, all ſuch as will farrow in about a month. Let little ſties, formed of boughs and reeds, be made for them in the moſt convenient parts of the clover ground, either in the corners, or under the hedges of theſe fields; and let the ſows be kept up, and fed daily with the turnips which were ſowed the autumn before. At firſt, it will be neceſſary to take the trouble of boiling them, tops and all, and of giving them in the troughs with the water not yet cold: they may afterwards be only ſcalded; and in a week or ten days the ſwine will eat them raw, with the greateſt greedineſs and pleaſure. In the beginning, or towards the middle of April, theſe ſows will farrow: after which they muſt not be fed with turnips any longer than till the clover is pretty high, when they and their pigs may be turned in among it. It is impoſſible for one who had not ſeen it, to imagine how eagerly the ſwine will graze on clover, which increaſes their milk to ſuch a degree, that the pigs ſhoot forward at a double rate; and as they leave off ſucking, they too take to feeding on the clover, by which they proſper ſo faſt, that by the end of October, every pig will fetch twenty or five and twenty ſhillings, in any market. The treading of great cattle is apt to break the ſtalk of clover graſs, and they ſpoil, by trampling it down, a much greater quantity than they eat: but ſwine are never hurtful this way; and if there be any fear of their rooting up the ground, that may be eaſily prevented by a ring in their noſes; though our author ſays, he never knew a hog break up an inch of clover. They graze upon it with more pleaſure than they could root.

Human ordure is a very fat and hot manure, full of fertilizing ſalts, and therefore extremely proper for all cold ſour ſoils, eſpecially if it be mixed with other dung, ſtraw, or earth, to give it a fermentation, and render it convenient for carriage. Some do not like to uſe it on account of its bad ſmell; and others imagine, that it gives a fetid taſte to plants; but in this they ſeem to carry their delicacy rather too far. It is uſed with great ſucceſs in many parts of France, all over Flanders, and, I believe, not leſs profitably round about London. Mr. Bradley ſays, it is kept in pits, made on purpoſe, in foreign countries, till it be one, two, three, or four years old: that of four years old is accounted the beſt; that of three years tolerable; but the others not ſo fit for uſe; and that the perſons concerned in theſe pits pay great regard to the place from whence they have it, preferring that which comes from towns where the moſt fleſh is eaten, as the ſtrongeſt and richeſt manure. It certainly ſhould not be laid on too new, nor in too great quantities, becauſe it is of a very hot nature; but when that heat is tempered by age, putrefaction, and a due mixture with other ſoils, it becomes a rich and excellent manure. Perhaps it may owe great part of this richneſs to the urine with which it is mixed; for tho' human urine be deſtructice to vegetables, whilſt it is new, by reaſon of its burning ſal-ammoniacal ſpirit, as Glauber terms it, yet, as in many other moiſt things, ſubject to putrefaction, time will correct that defect, digeſt the urine, take off its fiery quality, and ſo alter its nature, as to render it an extraordinary fertilizer of every kind of ſoil. Columella certifies, that old urine is excellent for the roots of trees. Mr. Hartlib commends the Dutch for preſerving the urine of cows as carefully as they do the dung, to enrich their lands, and inſtances a woman he knew near Canterbury, who ſaved, in a pale, all the urine ſhe could; and when the pale was full, ſprinkled it on her meadow, the graſs of which looked yellow at firſt, but afterwards grew ſurpriſingly. Similar to this is what Mr. Bradley relates, as of his own knowledge. Human urine was thrown into a little pit conſtantly every day, for three or four years. Two years after, ſome earth was taken out of this pit, and mixed with twice as much other earth, to fill up a hollow place in a graſs walk. The turf which was laid upon this ſpot grew ſo largely and vigorouſly, beſides being much greener than the reſt, that, by the beſt computation he could make, its graſs, in a month's time was above four times as much in quantity as that of any other ſpot of the ſame ſize, tho' the whole walk was laid on very rich ground. The author of the Engliſh Improver is therefore very right in ſaying, that human urine is of great worth, and will fatten land more than is generally imagined by our farmers, whom he adviſes to take all opportunities of preſerving this, and every ſort of urine for their ground, as carefully as is done in Holland.

The dung of all poultry is of a very hot nature, full of valotile

volatile ſalts, and therefore extremely proper for cold lands, being light of carriage, and a little of it going a great way. It is moſt commonly uſed for diſtant grounds, where it is ſprinkled on wheat or barley, after they are come up, or upon the latter at the time of ſowing. Mr. Mortimer thinks forty buſhels ſufficient for an acre. It is uſed to moſt advantage when dried and powdered, and is very efficacious in keeping froſt out of the earth. Its effects are ſudden, but they do not laſt long. Hens dung is very rich, though not ſo hot as pigeons dung, nor is it ſo eaſy to ſow, becauſe it hangs more together, neither can it be ſo eaſily collected. The opinion that gooſe dung is rather hurtful than beneficial to corn or graſs, is an ancient error, as is proved by Mr. Worlidge, who ſays, he was credibly informed, that a flock of geeſe having made a track a-croſs a field of wheat during the winter, and nibbed the corn clear from the ground in their daily paſſage in ſuch a manner, that the wheat upon it proved the next year much finer than any other part of the field. He alſo mentioned a field which had been given to the town of Sutton, in Northamptonſhire, for feeding geeſe, whoſe dung rendered it one of the richeſt paſtures he ever ſaw, inſomuch, that all ſorts of cattle fed on it very greedily; nor could he hear from any of the inhabitants, that ſo much as one beaſt received the leaſt injury from it. He adds, that his own horſes, kept in a piece of paſture on which geeſe lay very much, eat the graſs bareſt where the fowls had dunged moſt, and that he never found it do them any hurt, except making them too fat.

Perhaps the reaſon why the dung of geeſe has been ſaid to occaſion barrenneſs, flowed from obſervations where it had been laid too thick; for being of a hot fiery nature, it will, if laid on in too large quantities, deſtroy the graſs; but if ſpread thin in the winter, it will prove a very rich and valuable manure, eſpecially if mixed with cooling earth, and left for ſome time to putrify.

DUNG-HILLS, heaps of dung collected in the yard, and other places, belonging to a farm.

They are made up of the dung of different animals, of different kinds of ſtraw, and other vegetable ſubſtances; and they have frequently different animal ſubſtances in their compoſitions.

Compoſt, or compound dung-hills, are a collection of different matters, as earth, mixed with dung from an ordinary dung-hill, lime and other manure.

Some perſons make dung-hills of this kind, and are of opinion, that the dung and other manures with which they are compounded, are thereby made to enrich a greater quantity of land, than if not mixed with earth; and beſides, do not produce the bad effects which ſometimes are produced by dung, when taken directly from a dung-hill, and laid upon land.

It will not be amiſs that we enquire into the advantages of this kind of dung-hill, which will be a means not only of recommending them, but alſo of pointing out the moſt proper method of conſtructing them.

The firſt thing to be enquired into, is the advantage ariſing from the mixing lime, marle, or other manures, with the earth and dung. Lime, as it is a diſſolver of all vegetable and animal ſubſtances, when mixed with dung, will help to diſſolve it; and as it communicates an abſorbent power to earth, will enable the earth with which it is mixed to attract the vegetable food in greater plenty from the air. But in order to make it produce theſe effects, it is neceſſary to mix it with dung and earth; for if the lime is laid in a kind of ſtratum above the dung, and below the earth, it will abſorb the water that falls upon the dung-hill, and thereby will prevent the dung from receiving a ſufficient quantity of water to make it putrify; and will alſo occaſion ſuch a heat as to burn the dung, and render it uſeleſs; and beſides, can have but little influence in diſſolving the dung, and communicating to the earth its abſorbent quality. If the lime is laid above the earth, and expoſed to the air, it will be attended with the ſame conſequences: it will abſorb the water; and though it will attract the vegetable food from the air, yet will be of no more uſe for this end, than if ſpread upon as much land as the ſurface of the dung-hill extends to.

The ſame thing may be ſaid of marle, if uſed inſtead of lime; but if marle is uſed inſtead of earth, it is probable that the compoſt will become very rich, as the marle has a very ſtrong abſorbent quality, and would be greatly expoſed to the influence of the air. A much ſmaller quantity than is uſed in the ordinary way, it is probable, would be found ſufficient, and its effects would be ſooner diſcovered. If this is tried, it will be neceſſary to carry the dung to the marle-pit, and there form the dung-hill; for marle is ſo heavy a body, that it would be too expenſive to carry it firſt to the dung-hill, and then to the field.

The advantage of mixing dung with the earth is next to be conſidered. This, it is probable, is the principal advantage of the compound dung-hills, and that the advantages ariſing from lime are but trifling. They are often made without lime, and their effects, it is ſaid, are equally good.

Dung, in the ordinary dung-hills, has its vegetable food ſometimes waſhed away by rain, when it falls in large quantities. Now this is prevented by the earth in the compound dung-hill, which abſorbs the water, and all the vegetable food which it carries from the dung.

In the ordinary dung-hills, the dung on the ſurface, it is generally ſuppoſed, loſes a part of its vegetable food, which is exhaled by the ſun, or carried off by the wind. This is prevented, by covering the dung with earth in the compound dung-hill.

But it is probable, that the compound dung-hill receives its principal advantage from the earth being expoſed to the influence of the air; and if this be true, the more abſorbent that the earth is which is uſed, and the larger that the ſurface of the dung-hill is, in proportion to its bulk, and the quantity of dung contained, it will be the richer.

This directs us to the proper method of conſtructing it, to make it long and narrow, with as many diviſions in it as can be made conveniently; for thereby a larger ſurface is expoſed in the ſame quantity, and the more vegetable food acquired.

It is proper to obſerve further, that earth ſhould always be in the bottom of the dung-hill, to receive any of the juices of the dung which the rain may carry downward; that the dung ſhould be immediately covered with earth, to prevent the juices from being exhaled, or carried off; and that the earth ſhould be expoſed for a conſiderable time, before any more dung is laid on, that ſo it may receive all the benefit from the air which it is capable of, before it is covered.

This kind of dung-hills is made with leaſt expence upon the field for which the dung is intended. The head-ridges are commonly high raiſed, by the turning of the

ploughs

ploughs upon them, and contain the richeſt earth in the field. Theſe are very proper places for the dung-hills. The earth is at hand, and can eaſily be thrown upon the dung.

Thoſe that treat of dung-hills of this kind commonly recommend earth as oppoſite as poſſible to the nature of the ſoil upon which the dung is to be laid. They recommend clay for a light ſoil, and light earth for a clay ſoil. Beſides, theſe the farmer cannot always command; and, though he can, will frequently find it very expenſive to carry them. It is probable, that there is not ſo much in adapting the earth of the dung-hill to the kind of ſoil, as perſons, at firſt ſight, are apt to imagine. It is certain, that there cannot be ſo much in it, as to anſwer the expence of fetching the earth. It is true, that, in many farms, there are different ſoils, and therefore the dung may be carried to a ſoil different from the ſoil of the field for which it is intended; there the dung-hill may be formed, and from thence carried to the field; but ſtill this is an additional trouble and expence; and therefore this method is not to be followed, till, upon a comparative trial, the advantages are found to do more than anſwer the expence.

It is a practice in ſome parts of Scotland, to lay clay upon clay land. This practice, it is ſaid, ſucceeds very well, which makes it probable, that it is not very material what kind of earth is uſed for the compound dung-hill, provided it is of the abſorbent kind; and, therefore, the farmer need not be anxious about getting earth different from his ſoil, but may make his compound dung-hill of the earth of the field which he intends to manure.

Farmers, eſpecially if they live in countries that do not abound in cattle, may be apt to aſk, where they are to get ſufficient quantities of dung neceſſary for carrying the practice of agriculture ſtill nearer to perfection? M. de Tourbilly anſwers this queſtion, by pointing out the following method of making an artificial manure.

"Before the winter ſets in, ſays he, that is about the middle of November at fartheſt, huſbandmen ſhould cleanſe all the yards, and out-lets belonging to the farm-houſe; lay them ſmooth, and, if neceſſary, dig away a little of their ſurface, till it is about a foot lower than the floor of their buildings; then if they have any common or waſte land, let them bring from thence fern, thiſtles, and other coarſe weeds, cut down in full ſap, at which time they are beſt, or occaſionally as they are wanted, and lay a bed of them, about two inches thick, upon the places thus prepared. If weeds cannot be got, coarſe wheat or rye ſtraw may be uſed in their ſtead, in beds about half as thick. A layer of earth, about ſix inches deep, ſhould be ſpread upon this bed of weeds, or ſtraw. Earth of a quality proper for the improvement of the ſoil intended to be manured, is undoubtedly the beſt; though any earth, which in this caſe the farmer will dig as near to the houſe as he conveniently can, is preferable to the miſtaken practice of paring off the upper ſoil, or turf, of the neareſt common or waſte land, to mix with the artificial manure: for when poor ground has loſt its ſurface or ſward, it long remains a barren ſpot, before a new ſoil, capable of affording root and nouriſhment for graſs, can be formed upon it. If no proper earth lies nearer at hand, the farmer may take off the ſurface of any part of his ploughed ground which lies too high, and is not at too great a diſtance. But, as much as poſſible, he ſhould adapt the earth mixed with this manure to the nature of the land for which it is intended.

"This bed of litter and earth ſhould be let lie about a fortnight, during which all ſweepings and filth of the kitchen and houſe ſhould be thrown upon it, that nothing may be loſt, which can be converted into manure. The wetneſs of the ſeaſon, and the paſſing of men, cattle, and carriages, over this bed, will greatly contribute to rot it; to complete which, let the farmer turn in all his cattle of every kind, and drive them backward and forward over it, after rain has fallen. This will ſoon render it a kind of coarſe mud mixed with litter, which may be cleared away at the end of another fortnight. If it be too liquid, as it often is in rainy ſeaſons, it ſhould be laid up in little heaps, upon the ſame place, till it be drained. Let it then be carried to a ſufficiently capacious hole, or pit, dug for the purpoſe in or near a corner of the farm-yard. This pit muſt be in a dry place; for no manure ſhould ever be laid in water, which would waſh away its unctuous parts, deſtroy its heat, diſſolve its ſalts, and even leſſen its bulk conſiderably, if it run off elſewhere. One load of ſtable and other dung ſhould be mixed with every two loads of this artificial compoſt, as it is laid in the pit. The next day, another bed of litter and earth may be ſpread in the yard, &c. as before; and, being managed in the ſame manner, will be fit for carrying to the dung-pit in about another fortnight. Thus two ſupplies of this artificial dung may be had every month, during the whole winter and part of the ſpring.

"This work will not be expenſive: every body, even women and children may be employed at it, and it is done at a time of the year when labourers are leaſt wanted in the field. It may be continued in the ſummer: though the beds do not rot near ſo ſoon in dry weather; two or three months being ſometimes requiſite then to bring them to a proper ſtate, in the above method. However, this may be conſiderably haſtened, and much improved, by bringing cattle to lie upon them in the night, unleſs they are in folds. The earth and other ſubſtances of this manure will be greatly enriched by their dung and urine, before it is carried to the ſtercorary.

"As this laſt made dung will not be ſufficiently rotted by the next ſowing ſeaſon, the beſt way is to lay it in a ſeparate pit, to mellow, for the enſuing year; and it will be ſtill better, if kept two years. The other dung, made in a wetter ſeaſon, and more thoroughly putrefied at firſt, ſhould remain about ſix months in the pit, to ripen; and be wetted now and then in dry weather. During this time, it heats, ferments, and acquires an excellent quality. It may be made to ſuit any ſoil, and agrees with many lands better than pure dung taken from the ſtall or ſtable, than which it is milder, leſs fiery, and more laſting. Farmers who have not a large yard belonging to their houſe, may make this compoſt in any other place that beſt ſuits their convenience; and the poorer ſort of peaſants may do the ſame. By mixing with it a third part of other dung, they triple their quantity of manure." *Memoirs ſur les Defrichemens, p.* 78.

This eaſy and profitable method of making artificial dung is likewiſe recommended by the ingenious author of the Diſſertation on Agriculture, publiſhed in the Memoirs of the truly laudable Society eſtabliſhed at Berne, for the Improvement of rural Oeconomy.

"There are, ſays he, two ways of meliorating land. One of them may be called natural, and the other artificial.

ficial. The former conſiſts in a well proportioned mixture of two or three different kinds of earth, the reſult of which is a new ſort, more favourable to vegetation; and the latter in dung.

"Dung conſiſts of animal or vegetable ſubſtances, either actually putrefied, or in a ſtate of putrefaction. It operates two ways upon the earth: firſt, by conveying nouriſhment to the plants which grow in it, as the air and water alſo do; and ſecondly, by opening its pores and ſeparating its parts, by a kind of fermentation, till at laſt it is itſelf converted into a kind of fine black mould.

"The only way to have plenty of this uſeful matter, without much expence, is by a mixture of ſtraw or litter with the excrements of animals. Manure may be obtained from every part of animals or vegetables: but a quantity ſufficient for a large extent of ground would coſt too much. I therefore ſhall not here ſpeak of ſawduſt, tanner's bark, aſhes, ſoot, linen or woollen rags, ſhavings of horn, &c. of which quantities can be had only in the neighbourhood of populous towns; but ſhall content myſelf with pointing out the means of increaſing dung in countries diſtant from great cities.

"Agriculture affords an ample field, and very abundant matter, for the moſt uſeful of all experiments. Nothing would contribute more effectually to its improvement, nay, to the reducing of it to fixed and certain rules, than for proper perſons to try upon different pieces of ground, of ſimilar ſize and ſoil, ſome of the principal methods pointed out by the moſt intelligent in this art, and compare the iſſue of their trials, and the ſeveral incidents attending them, during a courſe of years. This is particularly wanted in order to determine the effects, and the quantity moſt proper to be uſed, of different manures. To this end, two or three fields of experiment might be ſet apart, to be cultivated exactly according to a well choſen and well digeſted plan. An exact account ſhould alſo be kept of every occurrence, diſburſement, and produce. Regularity is the ſoul of all buſineſs. Such journals, properly methodized, would give us a clear inſight into rural oeconomy, and ſet order, aſſiduity, and frugality in ſo advantageous a light, that every one would be forced to acknowledge them to be the ſource of riches, and as ſuch would be induced to practiſe them." *Tome* II. *part* III. *page* 651.

DURZ'D, or *dorz'd out*, an epithet, applied in the northern counties to corn beaten out of the ears by the wind turning it in the field, or other accidents.

DWARF-OAK, the name of a ſhrub common in many parts of North America, where it is planted for making hedges and fences. It grows very faſt, and becomes ſo thick by cutting with ſheers, that hardly a bird or mouſe can creep through it when in full perfection. The acorns are ſown in rows or drills, where the hedge is propoſed to be made, which admits of being made of a conſiderable height. Such a fence as this would be a ſcreen from the winds in winter, as well as a ſecurity to the incloſure; and therefore a hedge of this kind would be very uſeful here: and the plant would, perhaps, on further examination, be found capable of being ſerviceable in ſome other ways. *Muſeum Ruſticum, vol.* VI. *p.* 293.

DYER'S-WEED. *See the article* WELD.

E.

EADDISH, or *Eddiſh*, roughings, or graſs growing among the ſtubble, after the corn is cut.

EARING, or *Aring*, ploughing, tilling, cultivating.

EARNING, cheeſe-rennet.

EARTH, the ground, conſiſting of different modifications of terrene matter.

The earth, which generally preſents itſelf firſt to the eye, is no particular kind of ſoil, but, uſually, a mixture of the ſoil underneath, with every adventitious ſubſtance, either purpoſely brought to, or accidentally lodged upon it. From theſe cauſes, this ſuperficial earth, commonly called mould, grows and increaſes yearly in depth; oftentimes to ſuch a degree, as to form even conſiderable eminences, eſpecially where there has been a fall of woods and trees, ſuch as birch and beech, which, not being of a conſtitution to remain long in the ground without rotting, as fir, oak, elm, and ſome other timber will do, are pretty ſoon reduced into mould as ſoft and tender as that in which they were ſown or planted.

This ſurface-earth, and alſo the natural under-turf earth, to the depth of about a foot, is generally the beſt and ſweeteſt, being enriched with all that the air, dews, ſhowers, and celeſtial influences can contribute thereto: for that earth is beſt, and it is the ſame with water, which is moſt expoſed to the influences of the ſun and air. The fatneſs of the under-turf earth, drawn up to the

the ſurface by the kindly warmth of the ſun, ſpends but little of its vigour in the graſs and tender verdure which it produces, provided no rank weeds be permitted to grow and perfect their ſeeds; but maintains its natural force, and is therefore, of all uncultivated moulds, the moſt grateful to the huſbandman.

As the reſt of the ſubjacent earths approach this in virtue, ſo are they to be valued. Of theſe there are ſeveral kinds, diſtinguiſhable by their ſeveral conſtitutions. The beſt of them is black, fat, and at the ſame time porous, light, and ſufficiently tenacious, without any mixture of ſand. It riſes in pretty large pieces, and falls into duſt, of its own accord, after a ſhort expoſure to the air; but without crumbling altogether into duſt, which is the defect of a leſs perfect ſort.

This excellent black mould is fit for almoſt any thing, without much manure. The farmer is not always ſo happy as to meet with it: or if there be a ſmall depth of it, other, leſs fertile ſoils lie underneath, ſuch as clay, gravel, ſand, &c. which require different treatment, according to their various qualities. Theſe ſoils often appear on the ſurface; and may be ſaid to be almoſt barren, till brought by art to anſwer the purpoſes of the huſbandman. In clays and ſtiff ſoils, the component particles have too cloſe an adheſion to admit the roots of plants with the eaſe requiſite for them properly to ſeek their food: and, on the other hand, ſand, and ſoils of a light nature, are too looſe to give the proper ſtability to plants, or to retain the mixture neceſſary to convey their nouriſhment into them. It will therefore be right, firſt, to ſhew how theſe extremes may moſt properly be corrected, and then point out the means of keeping the ſuperficial mould in conſtant heart, to uſe the language of farmers.

EARTH-BOARD, that part of a plough which turns over the earth. *See the article* PLOUGH.

EAVES, the edges of the roof that over-hang the walls of a building.

EDDER, the ſmall ſhoots of aſh, hazle, oak, &c. uſed for binding the tops of hedges.

EDDISH, the ſame with eaddiſh. *See* EADDISH.

EDGE, the extremity of a border.

EDGE-GROWN, come up uneven, not ripening all together.

EDIFICE, a fabric, a building.

EFT, a newt, or evet.

ELBOW, a name given by horſemen to the hind-part of the fore-leg, pointing towards the briſket.

ELDER, fuel for fire.

ELDER, the udder.

ELDER, is alſo the name of a well-known tree, and is often uſed in making fences, which may be done by taking elder-ſticks, or truncheons, ten or twelve feet long, and ſticking them in the bank ſloping both ways, ſo as to form a kind of chequer work. By this means a fence may be ſooner raiſed than by any other, as the elder is a very quick grower. The wood, when large, is very uſeful for turners and mathematical inſtrument-makers, being nearly equal to the beſt box, and for many uſes ſurpaſſing it. *Mortimer's Huſbandry, vol.* I. *page* 7.

ELM, the name of a tree too well-known to need any deſcription, being common in almoſt every part of England.

Elms are very proper to be planted in hedge-rows, upon the borders of fields, where they will thrive much better than when planted in a wood, or cloſe plantation, nor will their ſhade be very injurious to whatever grows under them; but when theſe trees are tranſplanted out upon banks after this manner, the banks ſhould be well wrought and cleared from all other roots, otherwiſe the plants, being taken from a better ſoil, will not make much progreſs in theſe places. About Michaelmas will be a good time for this work, for the reaſons before aſſigned; but when they are planted, there ſhould be ſome ſtakes fixed in by them, to which they ſhould be faſtened, to prevent their being diſplaced by the winds; and part of their heads ſhould be taken off, before they are planted, which will alſo be of uſe in preventing their being eaſily overturned by winds; but by no means ſhould their leading ſhoots be ſtopped, nor their branches too cloſely cut off; for, if there are not ſome ſhoots left on to draw and attract the ſap, they will be in danger of miſcarrying.

Theſe trees are alſo proper to plant at a diſtance from a garden or building, to break the violence of winds, for which purpoſe there is not any tree more uſeful; for they may be trained up in form of an hedge, keeping them cut every year; which will cauſe them to grow very cloſe and handſome, to the height of forty or fifty feet, and be a great protection againſt the fury of winds: but they ſhould not be planted too near a garden, where fruit-trees, or other plants, are placed; becauſe the roots of the elm run ſuperficially near the top of the ground to a great diſtance, and will intermix with the roots of other trees, and deprive them of nouriſhment. Nor ſhould they be planted near gravel or graſs walks, which are deſigned to be well kept; becauſe the roots will run into them, and ſend forth ſuckers in great plenty; which will deface the walks, and render them unſightly.

But, for large gardens, where ſhade is required, there is ſcarce any tree ſo proper for that purpoſe, being eaſy to remove, when grown to a conſiderable ſize; ſo that a perſon who is willing to have his plantations for ſhade, in a ſhort time, may procure trees of one foot circumference in their trunk, which will be in no danger of ſucceeding, provided they are removed with care. And theſe will take root, and grow again, almoſt as well as young plants, which is what few other ſorts of trees will do; but then they ſhould be ſuch trees as have been thus regularly trained up in a nurſery, and have good roots, and not ſuch as are taken out of hedge-rows, as is by ſome practiſed, which ſeldom riſe with any tolerable roots, and conſequently often miſcarry; and this has been the occaſion of ſo many plantations of theſe trees failing; for although ſome of them may live a few years, yet few of them are of long duration, and they rarely increaſe much in their ſtems, but frequently grow hollow, their heart decaying firſt; ſo that they are ſupported only by their bark or ſhell, for a few years, and the firſt ſevere winter, or very dry ſummer, they are generally deſtroyed.

In planting of theſe trees, great care ſhould be taken not to bury their roots too deep; which is very injurious to them, eſpecially if they are planted on a moiſt loam or clay; in which caſe, if the clay is near the ſurface, it will be the beſt way to raiſe the ground in an hill, where each tree is to be planted, which will advance their roots above the ſurface of the ground, ſo that they

they will not be in danger of rotting in winter with moiſture.

When theſe trees are propagated by ſuckers taken from the foot of old trees, they are commonly laid into the ground very cloſe in beds, where, in dry weather, they may be frequently watered, to encourage their putting out roots. In theſe beds they are left two years; by which time, thoſe that live will be well rooted, though a great many of them generally die; then they ſhould be tranſplanted into the nurſery.

There are ſome who raiſe the witch elm from ſeeds, which it generally produces in great plenty, and are ripe in April. Theſe ſhould be ſown upon a bed of freſh loamy earth, and gently covered; in dry weather they ſhould be watered, and if the bed is ſhaded from the violent heat of the ſun, it will be of great ſervice to the ſeeds, for I always obſerve the plants to come up better in the ſhade, than when expoſed to the ſun. When the plants come up, they ſhould be carefully cleared from weeds; and after they have ſtood two years in the ſeed-bed, they will be fit to plant out into the nurſery.

Sometimes the common Engliſh elm will produce ſeed; but it is not ſo conſtantly fruitful as the witch elm, which ſeldom fails to produce great quantities, when they have arrived to due maturity; which ſeeds will fall to the ground, and when they light upon a ſpot which is not diſturbed, the plants will come up in great plenty.

The timber of the common Engliſh elm is generally preferred to the reſt; though that of the witch elm is often as good, and is the largeſt tree, when planted on a kindly ſoil; but the Dutch elm affords the worſt timber, and never will grow to the ſtature of either of the other ſorts; ſo that this ſhould not be cultivated for the timber; therefore the beſt way to be ſure of the kinds which a perſon would chuſe to propagate, is to have a nurſery of ſtools, in order to furniſh layers; for when they are grubbed up from hedge-rows, there will often be many ſorts intermixed, eſpecially if the people who go about to gather them, furniſh them; becauſe they take them indifferently wherever they can procure them; ſo that when they are planted out thus blended together, there will be a conſiderable difference in their growths, which will deface the plantation. *Miller's Gard. Dict.*

ERSH, the ſtubble after the corn is cut.

ERGOT, a ſort of ſtub, like a piece of ſoft horn, placed behind and below the paſtern joint.

ESCALLION. *See the article* SCALLION.

ESPARCET, the ſame with ſaintfoin. *See the article* SAINTFOIN.

ESSE, a provincial word uſed in Cheſhire, to ſignify aſhes.

ETCH, the ſame with erſh. *See* ERSH.

EVERLASTING-PEA, or broad leaved chickling vetch, a perennial plant, which grows naturally in ſome parts of England, is eaſily cultivated, and the root yields every year a great burden of excellent provender.

Theſe are great inducements for encouraging the cultivation of this plant, which ſeems adapted to any ſoil.

"I ſowed three years ago, ſays a writer in the Muſeum Ruſticum, a rood of land, light, and but poor in quality, with this ſeed: this work was done early in the ſpring, the land being prepared as for barley.

"I ſowed it not in the broad-caſt way, as I ſhould have found much more difficulty to keep down the weeds; but I cauſed a ſlight furrow to be drawn the length of the land with a light plough; and when the ſeed was thinly ſprained, or rather dropped into this, another was drawn at a foot diſtance, in which the ſeed was dropped in like manner.

"An interval, or fallow ſpace, was then left at leaſt two feet wide; then two more rows of the vetches, till the whole land was ſown. I muſt obſerve, that I covered the ſeed by means of a light harrow with wooden tines, drawn backward and forward acroſs the land.

"When the plants came up, I had them well hoed, to clear the ground of weeds; and when they grew a little ſtrong, they were ſet out with the hoe to about a foot diſtance in the rows, that they might have room to ſpread and branch.

"The firſt year they yielded no great quantity of fodder, but they have ſince made me ample amends.

"The ſecond ſpring they came up very ſtrong and vigorous, branching out much; and when I turned a couple of horſes in to feed, they were very fond of it, eating it very greedily, tho' they were taken out of a good, natural upland paſture.

"This laſt ſummer the land was almoſt entirely covered, and it yielded a great deal of ſeed indeed; for experiment ſake I cauſed a few rods to be mowed juſt before it flowered, and it made good hay, ſweet, without being ſticky.

"Before I conclude, give me leave to obſerve, that when I had cut a few rods of the everlaſting-pea, to make into hay, a ſmall quantity of it was, by accident, ſpread thin upon the ground, ſo as to receive the full action of the ſun's rays: this was, in a manner, ſpoiled, becoming quite dry, inſipid, and brittle, and almoſt all the leaves dropping off; but the remaining part, which was dried either in ſmall cocks, or thick ſwarths, made excellent hay. I am, however, perſuaded that the laſt method is by much the beſt." *Muſeum Ruſticum, vol.* I. *p.* 468.

EWE, the female ſheep. *See the article* SHEEP.

Mr. Ellis, in his Treatiſe on Sheep, has given us the following ſecret, which he poſitively aſſerts will make ewes take ram, at any time of the year. "Separate, ſays he, ſix or more of your ewes from the flock, and give to each half a pint of ſtrong ale, or the ſame quantity of good October, mellow, ſilky beer, and not that which is ſharp by ſtaleneſs; and for giving it in the eaſieſt and ſafeſt manner, you may run the ale or beer through a funnel into the ewe's mouth; and when the ewes have been all thus ſerved, put them into a proper place, not too large, nor too narrow, that the ewes may be confined with one or more rams, that have been before a little better kept than ordinary for this purpoſe. Out of ſix ewes, that I have known to take ram in this manner, not one of them has failed proving with lamb. By the above method, and the aſſiſtance of a ſufficient number of hands, an hundred ewes may be thus doſed with ſtrong drink, and if rams enough are provided, they will all preſently take ram." *Ellis on Sheep, p.* 297.

EXERCISE, a proper agitation given to an animal body, in order to produce ſalutary effects.

Exerciſe duly given to horſes that are well fed, is not only the beſt means of all others to prevent ill habits, but to preſerve them in a perfect ſtate of health: for exerciſe converts the food into good and wholſome nouriſhment, it promotes the circulation of the blood, and all the glandular diſcharges, ſo as greatly to enliven the body, and to

make way for freſh ſupplies of aliment. It invigorates the ſpirits, gives ſtrength and firmneſs to the muſcles and ſinews, and enables a horſe to endure labour. And when exerciſe is given abroad, in an open free air, it adds greatly to a horſe's vigour, and prevents any diſpoſition to putrid coheſions in the blood, which a cloſe ſtagnated air often produce, and this eſpecially when horſes are young, and their appetites ſtrong; for indeed when horſes grow old, their appetites are more moderate, and reſt is oftentimes more agreeable to them than labour. Nevertheleſs, exerciſe is, more or leſs, abſolutely neceſſary for all horſes, young or old: for we may obſerve, even old horſes, when they lie much ſtill, though they are not apt, as young horſes, to turn directly ſick, and fall into fevers: yet as their blood grows poor, and languid with age, they become ſubject to many infirmities, as ſwellings of their ſheath and bellies, with other dropſical ſymptoms, and ſometimes to obſtinate eruptions on their ſkins, which exerciſe in a proper degree often prevents.

Horſes, by their natural activity, are every way ſuited to exerciſe and labour, and in that reſpect are more uſeful than any other of the brute creatures; only it depends on us, how they are to be treated, both for their own preſervation, and our benefit; and their food ought always to be proportioned according to their exerciſe. But the time and manner of a horſe's exerciſe is alſo to be regarded, for if he happens either to be worked at an unſeaſonable time, or beyond his ſtrength, it will be more injurious to him than if he had not been worked at all. Therefore this general caution is always needful, viz. never to ride a horſe hard, or put him upon any violent exerciſe when he hath been newly fed, and has his belly full of meat or water; but ſhould be moved out at firſt gently, and he will naturally mend his pace, as his food and water begins to aſſuage, when his rider may urge him on to further ſpeed, as his buſineſs may require.

I need not tell any one, that when a horſe is hot with riding, or any other ſharp laborious exerciſe, he ſhould be cooled by degrees, this being known to almoſt every ſtable boy, from cuſtom and uſe, though it is often neglected, through ignorance or idleneſs, or done with little judgment. And, therefore, when a man has travelled hard upon a journey, or when horſes have been driven hard in a coach or chaiſe, it is not ſufficient, after they come to their bating place, or to the end of their day's journey, to walk them about in hand for half an hour or more, which is uſually done, but their pace ſhould alſo be ſlackened for a mile or two before they come in, and after that, ſhould alſo be walked ſome time in hand, that they may cool gradually before they are brought into the ſtable, with a thin cloth laid over each, if they have been uſed to it. This is the ſafeſt way with young horſes, that have been kept well, and have worked but little. And when ſuch horſes come late to the end of their day's journey, or when the weather is ſo bad, that they cannot be walked about in hand, they ſhould then be well rubbed all over their bodies and limbs, till they are quite cool, without taking off their harneſs and ſaddles, and then cloathed; for when all the ſmalleſt blood veſſels are replete and full, as they muſt unavoidably be in all ſtrong, and eſpecially in long continued exerciſe, and the blood extremely heated, and running like a torrent, any ſudden chill or damp will produce ſtoppages and obſtructions, where the veſſels are the moſt minute and ſmall, or wherever there is the greateſt weakneſs and relaxation, ſometimes inwardly in the lungs, ſometimes in the liver and kidneys, and ſometimes in the ſtomach and guts, and other membraneous parts; and this is uſually followed with inward pain, and inflammation, or with great dulneſs and heavineſs, which, in the end, often produce many untoward diſorders; or if the limbs happen to be weak and relaxed, the blood and juices will ſoon drop down and ſtagnate there, ſo as to produce ſwellings, and ſometimes ulcerations, that are troubleſome enough to remove, eſpecially in thoſe that have been little accuſtomed to ſuch kind of labour; for habit and uſe, in continued exerciſe, alters the caſe very much, becauſe that ſtrengthens and invigorates the nerves and ſinews, as we obſerve in ſome hackney or job horſes, which are ſo ſeaſoned to their work, that ſcarce any thing can hurt them. Indeed ſome of the job horſes, that we ſee endure ſo much labour, are naturally ſtrong, and very hardy, and have at firſt been carefully managed by their owners, who are not able to bear the loſs of cattle, as gentlemen or men of fortune; and, therefore, we ſee them generally, both begin and end their work with great coolneſs, and when they chance to meet with horſes that they find unable to go through their hard work, they uſually make their buſineſs only a mere play, that they may not loſe their fleſh, until they can diſpoſe of them to the beſt advantage. Another neceſſary caution for the preſervation of our horſes, is never to feed them too ſoon, after they have been heated with exerciſe. *Gibſon's Farriery, vol.* I. *pag.* 182.

EXPERIMENT, a trial of any kind; an eſſay made in order to diſcover an uncertain, or unknown effect.

For the ſeveral experiments made on wheat, barley, &c. *ſee the proper articles* WHEAT, BARLEY, &c.

EYE, the organ of ſight in an animal body; or that which repreſents objects to the mind.

The goodneſs or badneſs of the eyes of horſes is a thing wherein the beſt judges are ſometimes miſtaken; for moſt people regard the clearneſs and tranſparency of the eye, which indeed ought to be conſidered: but it is worth obſerving, that horſes, before they are ſix years old, have not that tranſparency in their eyes which they arrive at afterwards, becauſe while they are young and growing, their juices are viſcid and balſamic; ſo that their eyes look thicker or clearer, in proportion as their blood and juices happen to be more or leſs in a good ſtate. The ſame may be obſerved in all horſes that have colds, when the veſſels of the eyes are full: the eyes at that time look thick, and ſometimes inflamed, and a blow on the eye, or a bite, will have the ſame effect, when there is not the leaſt danger of blindneſs.

It is not, therefore, always the clearneſs of the eye that denotes its goodneſs, but a man is alſo to form his judgment from other indications, particularly from the form and manner of the eye, which includes not only the body of the eye, but the eye-lids, eye-brows, and all the parts belonging to it. Many good eyed horſes have a heavineſs in their countenance, with a lowering-brow, yet great numbers of this aſpect go blind with cataracts when they are about ſeven years old, or between ſeven or eight, and ſometimes later. Theſe are the moſt ſuſpicious where there is a bunch or fullneſs between the upper eye-lid and the eye-brow, with a fullneſs round the under eye-lid; ſo that the eye appears as if it was invironed in a ring. Such horſes are often fleſhy about the head and jaws, which,

upon

upon every cold, or rather ſlight accident, expoſes them to defluxions in their eyes.

When the eye is extremely flat or ſunk within its orbit, it is always a bad ſign, even though there be no defluxion or humour upon it: a ſmall pig-eye is none of the beſt, nor a large gogling eye.. The one often periſhes for want of nouriſhment, occaſioned by ſome defect in the nerves or the arteries that ſupply it with blood; the other by being too much expoſed to accidents, and by having too great ſupplies of nouriſhment.

That eye is almoſt always weak which is of a longiſh oval figure, eſpecially where the two corners are narrow, like the ſhape of an almond. When the coat or membrane, that riſes from the under part of the eye happens to be large and thick, ſo as to preſs the eye-ball, and the caruncle or kernel on the inward corner next the noſe is ſpongy and moiſt, though there is ſometimes a remedy for this defect, yet ſuch horſes in the end generally go blind.

When the eyes are bad, the muſcles or movers of the eyes are generally weak: ſo if the eye looks dead and lifeleſs, the beſt way of trial is to hold up the horſe's head in the ſame manner as when a drench is to be given, which will draw the eye upward; and if it remains there fixed and immoveable, or has a languid motion, it is a pretty ſure ſign the eye is bad. And this trial will, for the moſt part, hold good whether the eye be moiſt or dry.

Some regard the colour of the eye, which, however, is different according to the difference of colour in horſes; and indeed we are ſo far to regard the colour, that if the iris or circle that ſurrounds the pupil or ſight of the eye be diſtinct, and of a pale variegated cinnamon colour, it always denotes a good eye. For the iris is always moſt diſtinct, where the humours of the eyes are moſt clear and pellucid; and thoſe horſes have the beſt eyes, which in colour reſemble the eyes of a ſheep or goat; but few horſes arrive to that perfection of colour and tranſparency, till they are at leaſt ſix years old or upwards. On the other hand, if the iris or circle round the pupil be of a dark muddy colour, and does not appear diſtinct and variegated, till one approaches near the eye, and if the narrow ſky-coloured verge, which we obſerve more or leſs in moſt horſes on the outſide of the iris, happens to be of a milky hue, it is of no good ſign. Nevertheleſs, wall-eyed horſes have for the moſt part good eyes.

Some in examining the eyes have a regard to the colour of the horſe, which I take to be no ſure way of judging; for as there are good horſes of all colours, ſo there are good eyed horſes of all colours. The grey, eſpecially the pigeon or dove-coloured grey, are the moſt ſuſpected; alſo the iron-grey, and the dun, &c. But I think I may ſay from experience, that whatever colour is the moſt common among the horſes, ſo as to exceed in number, abounds moſt with bad eyes: and I have obſerved as many bad eyed horſes among the black coach breed as any other.

Moſt people in examining a horſe's eyes lead him under a gate-way, or ſome ſhade, that they may ſee perfectly the colour and tranſparency of the eye: but the beſt way is to obſerve his countenance when he comes firſt out of a dark ſtable into a ſtrong light; for if he has any weakneſs in his eyes, he will wrinkle his brow, and look upwards to receive more light; and if the pupil at the ſame time be large, it is a bad ſign; and therefore the beſt way is to look to a horſe's eyes firſt in the ſhade, to obſerve the dimenſions of the pupil, and if that leſſens upon his coming out into a ſtrong light, it is almoſt an infallible ſign that the eye is good.

Some ſuſpect all horſes that ſtartle to have bad eyes; indeed many bad eyed horſes are apt to ſtartle: but a horſe that ſtarts and looks upwards, lifting his feet high when he moves, as if afraid to touch the ground, ſuch is more likely to have bad eyes than one that ſtartles; for many horſes ſtartle merely out of fear, and I imagine not a few from ſome defect in viſion, viz. from ſeeing objects indiſtinctly at ſome diſtance, in all which caſes the eyes may be ſtrong and durable, though many fancy them to be weak. But if a horſe frequently ſtartles when no object is before him that might cauſe him to ſtartle, we may then ſuſpect his eyes to be but indifferent.

Upon the whole, that eye is generally good where the eye-lids are thin, where the outward coat or tunicle of the eye is alſo thin and delicate, where the caruncle next the noſe is ſmall and dry, where the eye is tranſparent and ſprightly, when a horſe has a bold reſolute look, and takes notice of objects without fear. On the other hand, when a horſe moves his ears backwards and forwards, and ſeems ſurpriſed at every noiſe or motion of the hand; when he raiſes his feet high, is uncertain in his walk or ſtep, and unequal in his goings, when his eyes appear full and ſwoln with a fleſhy circle round them, or when they are ſunk or flat, or of a longiſh oval figure, when the outer coat is thick and covers a great part of the eye-ball, and the glands or kernels of the eye are ſpongy and moiſt, all theſe denote the badneſs of the eyes, and are often the forerunners of blindneſs. *Gibſon's Farriery, vol.* I. *page* 14.

EYE *of a tree*, a ſmall pointed knot to which the leaves adhere, and from which the ſhoots or ſprigs ſpring forth.

EYE, among gardeners, implies the ſmall bud or ſhoot inſerted into a tree.

EYE-LID, the membrane that covers the eye.

If the eye-lid of a horſe is wounded and cut through, and the cut divides it ſo as the lips part one from the other, it ought to have a ſtitch with a ſtrait needle, ſuch as the ſurgeons uſe for ſuperficial wounds, and not to be drawn too cloſe, but juſt ſo far as to bring the edges together; and this is yet the more neceſſary when the eye-ball happens to be wounded through the eye-lid, that there may be room for the diſcharge of the matter. I have obſerved that the eye-lid requires but one ſtitch, for when there are more, and theſe purſed together, as the farriers generally do, and the lips drawn cloſe, ſuch ſtitches will break in twenty-four hours, and leave the wound in a worſe condition than it was at firſt.

The proper dreſſing for wounds of the eye, is honey of roſes, and tincture of myrrh, viz. one dram of the tincture to an ounce of the other. The beſt way of uſing it is to dip a pledgit of lint in this mixture, made warm, and applied to the wound, for tow and hurds are too harſh for the eye. This dreſſing may be repeated once a day, until the wound is healed up and cicatriſed, and it will ſeldom fail of ſucceſs. *Gibſon's Farriery, vol.* I. *pag.* 320.

F.

FALLOW, land ploughed, but not ſown, being left to reſt after the years of tillage.

If the farmer finds that one ſummer's fallow does not entirely anſwer the purpoſe of dividing and looſening the earth, it is his intereſt to continue it for another. M. Tull confirms this, by inſtancing a poor man, whom neceſſity compelled to take this method, becauſe he could not get ſeed for his ground after he had tilled it the firſt year. The conſequence was, that his crop was worth more than the value of the land it grew on. Mr. Maxwell too mentions another, who, from a like neceſſity, followed the ſame courſe upon almoſt his whole farm, had ſuch a crop as enabled him to pay many debts, and, by continuing the ſame practice, came in a few years to be in a condition to purchaſe the farm.

When the huſbandman intends to break up any piece of land, the firſt thing neceſſary is carefully and judiciouſly to examine the ſurface of the ground, and its depth. If the ſurface be covered with a thick, ſtrong, fibrous turf, and the mould underneath ſufficiently deep, his beſt, and indeed the only right method of proceeding, is excellently well directed by the marquis of Turbilly. But if, on the contrary, the upper mould ſhould be ſhallow, or ſo thin turfed as not to be fit for burning, he muſt obſerve, whether his ſoil be of a ſtrong, or of a light quality. Under the former of theſe are included all deep hard clays, of what colour ſoever; all ſtiff binding earths, and ſuch as, after being expoſed to the ſun, or froſt, grow hard and ſtony; with ſuch as chop and cleave upon their ſurface in the heat of ſummer: and under the latter are ranked (the repetition may be excuſable here for the ſake of perſpicuity) all ſandy, mouldering, gravelly, mellow ſoils; all looſe and open earth, of what nature ſoever; all ſuch as are not ſticky, but will ſoon dry after rain; and, inſtead of lying in great lumps after ploughing, are eaſily apt to diſſolve, and crumble into mould, not being ſubject to bind by the heats in ſummer, or froſt in winter.

If, upon examination, the ſoil is found to be of the ſtiff kind, particular care muſt be taken to turn down its ſurface in the latter end of autumn, that what fibrous roots there are in it may be the more effectually rotted againſt the ſummer ploughing, and that the earth may be mouldered, or mellowed, by the winter's froſt and rains.

When ploughed land is intended to be fallowed, it ſhould likewiſe be ploughed in the autumn, as ſoon as the ſeed time permits, and laid as rough as may be, eſpecially if it be a ſtiff ſoil, that the winter's froſt may mellow it.

In the ſpring, the farmer ſhould take the earlieſt opportunity that his ſpring crops may admit of, to give his fallows a ſecond ploughing acroſs the former; after which the ground ſhould be well harrowed, not only to break the clods, but to pull up ſuch roots as are not yet rotted, that they may be gathered into heaps and burnt. It is eſſentially neceſſary that this, and all the following ploughings and harrowings be performed in dry weather; becauſe, as the purpoſe here is thoroughly to looſen the mould, ſpecial care ſhould be taken to avoid every thing which might counter-act that intention. The farmer cannot wiſh for a greater benefit to his huſbandry, than moderate ſhowers after each fallow, to bring the ſeeds of every weed to vegetate, in order that, being turned down by the ſeveral ploughings, they may be the more effectually deſtroyed.

It ſeems needleſs to mention when the future ploughings ſhould be given, becauſe the farmer ſhould take every opportunity of repeating both them and the harrowings, in full confidence that he cannot over-do it, eſpecially in ſtrong ſoils; in which he may alſo be equally certain, that he cannot err in ploughing too deep: for it is of great conſequence, not only that the roots have a ſufficient depth of mould to penetrate in, but alſo that the cold clay be removed to as great a diſtance as poſſible from the ſurface; becauſe by its retaining the water, the roots of plants are chilled and killed, eſpecially in the winter, when they reach ſuch ſtagnating wet. If any manure is applied to alter the quality of the ſoil, it cannot be laid on too early in the ſummer, that the ploughings may the more effectually mix it with the earth; but if only compoſt be uſed for enriching the ſoil, it need not be ſpread till juſt before the laſt ploughing.

Authors give directions for ploughing land into many different forms, moſtly ariſing from the different natures of ſoils, but too often from the particular long eſtabliſhed cuſtom of countries, the reaſonableneſs of which is not always ſufficiently conſidered.

Where there is a deſcent for water, all lands ſhould be laid flat, becauſe, in that way, the rains will undoubtedly give a more equal nouriſhment to the crop, than when they are raiſed in ridges. The practice of laying light ſoils into narrow ridges, for wheat, is certainly owing to want of attention; and even in ſtrong land ploughed for winter fallowing and ſowing, we are much inclined to think that the beſt way would be, inſtead of ſingle bouts, or narrow ridges, to make the ridges very broad, and lay them up high: for if the ground is level, the water will lie in the parting thoroughs, and, by ſoaking into the ſides of the ridges, make it ſo poachy, as to render it very unfit to be worked, till late in the ſpring, unleſs the ſeaſon be very dry; or, if there is much deſcent, great part of the beſt ſoil will be carried off. For the ſame reaſons the ſides of hills ſhould always be ploughed almoſt, but not

quite,

PLATE XV.

A Fallow-cleaning Machine, Invented by Mr. Aaron Ogd
Manchester in Lancashire.

Fig. 1.
Drill Rake.

Facing Fallow-cleansing Machine.

on Ogden, a Smith at Ashton Underline, near

Fig. 3.

Fine Bent

quite, horizontally, that the parting thoroughs, lying open, may ſerve for drains to the water: beſides which, the ploughing of ſuch declivities in this ſloping manner is by much the leaſt laborious both to men and cattle. The furrow here ſhould always be drawn oblique, as Columella directs, ſometimes a little toward the higher, and ſometimes toward the lower part of the hill, ſo that the direction may be altered in each ſubſequent ploughing.

The erroneous opinion of thoſe who imagine that the ſurface of the ground is conſiderably enlarged by ploughing it into high ridges, and that it therefore affords a larger ſpace for the growth of plants, is thus judiciouſly refuted by M. Duhamel.

"The produce of a ſloping ſurface is not greater than that of a plane equal in extent to the baſe of the ſlope: for as the plants grow perpendicular to the horizontal baſe, there is no point of the ſlope which does not anſwer vertically to a point of that horizontal baſe: therefore ſuppoſing the furrows of a piece of ground ploughed in broad lands to be ſix inches deep, and the ridges ſix feet wide; the ſlope from the bottom of the furrow to the middle of each ridge will be one foot in ſix, which is indeed conſiderable: but ſtill the ſurface of the ridges will be to that of their horizontal baſe, only as ſeventy-ſix are to ſeventy-five: a ſmall advantage; eſpecially when compared to a fixth part of the ground, which is taken up by the furrows, and in which no corn is ſowed."

Another, and that very eſſential, advantage of fallowing, not yet ſufficiently inſiſted on, is the deſtruction of weeds, which are one of the farmer's greateſt enemies. By weeds, we here mean every plant which grows ſpontaneouſly in the field, without having been purpoſely ſown, and which it is not the huſbandman's intention to cultivate. All theſe ſhould be rooted out. It would be needleſs to enumerate them after this general definition; and perhaps equally ſo to obſerve, what every huſbandman muſt know, that cockle, darnel, fox-tail, wild poppies, wild vetches, wild oats, dog's graſs, colt's foot, melilot, knot-graſs, thiſtles, and charlock, are the moſt hurtful ſpecies of theſe noxious growths, and the moſt difficult thoroughly to extirpate.

To prevent the increaſe of weeds, they ſhould be deſtroyed before their ſeed is ripe: but that is not poſſible in lands which are ploughed in the common way; becauſe, as they grow intermixed with the corn, and ripen ſooner than wheat, their ſeeds ſow themſelves; neither can they be extirpated by reſting the land; for the ſeeds of ſome of them will remain ſound ſeveral years in the earth. If a field in which there are many poppies, or red weeds, as they are called in ſome places, be ſowed with ſaintfoin, ſcarce a poppy will appear the ſecond year: but when the ſaintfoin is ploughed up, even at the end of nine years, the red-weed frequently appears a-new, which can hardly be owing to any other cauſe, than that its ſeeds have remained ſound in the earth during all that time; for very few of them, in proportion to the quantities which ſpring up, can have been brought from the neighbouring grounds, or in dung. This is confirmed by an experiment which M. Duhamel made. He ordered the earth, with which a ditch had been filled fifteen or twenty years before, to be dug out, and ſpread upon a piece of ploughed land. Several plants, of different kinds from any that were in the field, ſprouted up in the place where this earth was laid. Conſequently they were produced by ſeeds which had remained ſound in the ground, during the fifteen or twenty years that this earth had lain in the ditch.

This is an important reaſon for ploughing thoroughly all lands which are fallowed; for it is certain, that as numbers of ſeeds ſhoot up during the fallow, repeated ploughing will deſtroy many of them. But there are ſeveral kinds of plants, ſuch, in particular, as wild oats, and fox-tail, the ſeeds of which do not ſprout till they have remained two or three years in the earth; nor will culture make them grow ſooner. Such, at leaſt, is M. Duhamel's opinion, as well as that of ſeveral other very ingenious gentlemen, though it muſt be confeſſed, that ſome late experiments ſeem to contradict it, and to ſhew that the ſeeds of thoſe plants which he ſays require being three years in the ground before they will grow, were only buried ſo deep, in the caſe he mentions, as not to be able to vegetate, which they afterwards did when laid within reach of the influences of the air, rain, dew, &c. If ſo, though the increaſe of weeds may be prevented for ſeveral years, by ploughing, cutting, pulling them up, &c. yet it is evident, that the repeated ploughing of fallow lands, far from immediately deſtroying theſe kinds of weeds, will rather help them to grow, when their ſeeds are brought within a proper diſtance from the ſurface, and their time of ſprouting is come. But then, allowing that ſome of their ſeeds may be thus brought up by each ploughing, for a while, it cannot be long before all of them will have ſprouted, after which the ground may be kept quite clear, with proper care.

Huſbandmen have not yet found a more effectual method to deſtroy weeds, than by ſowing the ground out of ſeaſon; that is to ſay, by ſowing oats the year that barley ſhould be ſowed. It has been experienced, that, by this means, ſome kinds of weeds have been deſtroyed, which, appearing only every third year, never ſhews themſelves, in the uſual rotations, but amongſt wheat. But the farmer loſes a crop by this means, and ſtill has ſo many weeds left, that he is obliged to hire people to weed his corn. This is done two ways.

A number of women place themſelves in a row, and, with a hoe made for the purpoſe, cut up all the weeds they ſee, ſuch as thiſtles, blue-bottles, poppies, &c. But many of theſe, when young, frequently eſcape their notice; in which caſe the hoeing muſt be repeated when they are grown larger; and the ſmaller weeds, ſuch as wild vetches, wild oats, darnel, knot graſs, fox-tail, young poppies, &c. which are at leaſt as hurtful as the other, remain in the field. Beſides this, in cutting the weeds, it is ſcarce poſſible not to cut down ſome of the corn; and the roots of the thiſtles and other biennial plants which are cut, produce two or three new ſtalks in lieu of the old one; by which means the evil is increaſed.

The other method of clearing corn, is by hand-weeding it; but this is ſeldom practiſed by farmers, becauſe it is too expenſive: and indeed the women and children generally employed to do this work, moſt commonly pull up a great deal of corn with the weeds; ſo that, what with that, and with their trampling, and dragging their bags of weeds over it, they frequently do more hurt than good, eſpecially if the earth be moiſt.

The ſureſt way to deſtroy weeds, is to continue ploughing while the corn grows: but this can be done only in the New Huſbandry.

Weeds may be ranked under four general claſſes: firſt, ſuch as have creeping perennial roots: ſecondly, ſuch as

grow

grow in cold wet ſoils: thirdly, ſuch as are of a large ſucculent body; and, fourthly, ſuch as having ſmall ſeeds, or ſeeds which ripen before the corn, ſow themſelves. Each of theſe require a different treatment.

The firſt ſort cannot be deſtroyed but by repeated ſummer fallows, by which their roots are cut, and turned up to be withered by the ſun and winds, after which they are dragged out by harrows, and ſhould be burnt. This, repeated as often as the farmer conveniently can, eſpecially during a dry ſeaſon, can ſcarcely fail to have the deſired effect. Colts-foot, which is propagated by the root, and is a very pernicious weed, may likewiſe be deſtroyed by ſowing the ground with rye-graſs, or any plant which, coming up early in the ſpring, ſhades and ſmothers it; for that will kill it in a few years. The ſecond kind are deſtroyed by draining the earth of its ſuperfluous moiſture, and by manuring it with lime, aſhes, gravel, ſhelly ſea-ſand, and other proper correctives for ſuch ſoils.

The third are extirpated by cutting them down when in full ſap and vigour: for the ſap being thereby ſuddenly interrupted in the courſe of its circulation, ſtagnates in the roots, and putrifies there. A few weak lateral ſhoots may be made; but if they are likewiſe cut in the ſame manner, the roots will putrify intirely by degrees, and inſtead of annoying, will become a manure.

The fourth claſs can be deſtroyed only by frequent fallows, and conſtant cutting, or rather ploughing them down before they run to ſeed. Some, for inſtance the wild oats, may be mowed for hay: but it is much more beneficial to the land to plough them in: becauſe, by that means, inſtead of being exhauſted by frequent crops, it is manured by thoſe enemies to uſeful grain.

FALLOW, alſo ſignifies a pale red colour.

FALLOW-CLEANSING *Machine*, an inſtrument invented by Mr. Aaron Ogden, a ſmith at Aſhton-under-Line, near Mancheſter, in Lancaſhire.

This machine, which bids fair to be of very great uſe in huſbandry for cleanſing fallows from weeds, &c. which waſte the riches of the ſoil, will be very eaſily underſtood from the drawing we have given of it on Plate XV. Fig. 2. Where,

A, A, is the frame; B, the firſt roller; C, the ſecond ditto, in which laſt are two cranks to move the arms D, D, which work the rake up the directors fixed on the plank E. The under ſide of the lower ends, or ſhares, of theſe directors, are ſharp to cut the clods, and let them come on the upper ſide. Each alternate heel of the ſhare is longer than the intermediate one, that they may not have more than one half to cut at once.

At the back of the plank E, are two ſcrews to let it looſe, that the directors may be ſet higher or lower. The ſhares are to penetrate the ground two or three inches, to raiſe the quicks till the rake I, I, fetches them into the cart H, where a man muſt be ready with a muck-hook to clear them backward when gathered.

In the rake I, are two teeth for every ſpace of the directors, that ſtones, &c. may be gathered without damage.

K, K, are two ſtaples, by which the machine is drawn: under them at *b*, are two hooks, placed low to raiſe the machine in turning, by the help of the traces; and the axle-tree of the cart ſhould be fixed upon a pin, that it may turn like a waggon.

F, F, are the triggers to throw the rake behind the roots. The long teeth at G, G, are to cleanſe the roller C. I, I, is the rake which gathers up the weeds into the cart H, and is drawn above the trigger F, by the working of the arms D, expreſſed by the dotted lines at *d d*, *i i*.

The triggers F, of which there is one on each ſide, move on the pivots *a*; ſo that when the points *b*, of the rake I, having been drawn up by the directors E, to the part marked *c*, the trigger, giving way, permits the rake to paſs; but immediately falling, the rake returns along the upper ſurface of the trigger marked *e*, *e*, and of courſe falls on the weeds when it comes to the end, a little beyond the pivot *a*.

The reader will obſerve that the boarding is taken away on one ſide, in the Plate, in order to give a more perfect view of the inner parts of the machine; and, in fact, it would, perhaps, be better if all the boarding, marked L, L, L, was taken away, and frame work put in its ſtead.

The cart H, might undoubtedly alſo be made lighter.

The wheels M, M, appear, in the plate, to be made of ſolid wood; but there is no neceſſity they ſhould be ſo.

At N, is another view of the roller C, by which the diſpoſition of the ſpikes may be eaſily comprehended.

Suppoſe the circle O, deſcribed by the end of the roller N, to be divided by four ſtrait lines into eight equal ſegments, as repreſented at P. Let the ſame be done at the other end of the roller, and parallel lines be drawn from one correſponding point to the other, the length of the roller: mark the points with figures 1, 2, 3, 4, 5, 6, 7, 8; afterwards draw oblique lines, as from 1, at the end O, to 2, at the other end, and from 2 to 3, &c. on theſe oblique lines the ſpikes are to be fixed, at equal diſtances, in eight circles, deſcribed on the circumference of the roller.

The ſpikes of the ſmall roller B, are fixed in the ſame manner, except that, the diameter being ſmaller, there are only ſix inſtead of eight rows.

R, is another view of the directors, with the plank E, on which they are fixed; and S, is a ſection of a part of the plank, with one of the directors as fixed, in which may be ſeen the heel *m*, from whence to the point of the ſhare *n*, is a ſharp cutting edge. See the ſame letters in figure R.

At T, is one of the long teeth to be ſeen at G: it is bent towards the roller C, which it ſerves to cleanſe. When the end of the rake *b*, after riſing above *c*, is puſhed, by the motion of the arms D, D, along the upper part *e*, *e*, of the trigger F, and comes to the end beyond *a*; as it falls, the part of the arm, marked *o*, reſts in the notch *p*, till it is again raiſed by the motion of the roller C, with the rake.

The roller C, is to be one foot diameter, the ſpikes nine inches long, that they may go through the furrow (if the ſoil ſhould be looſe) into the hard earth, the more effectually to work the rake, which otherwiſe might be ſo over-charged as to cauſe the roller to drag without turning.

In the rake-ends *b*, there ſhould be pivots, with rollers or pullies on, to go in the groove, to take off the friction; and they would likewiſe take the triggers more ſurely as the rake comes back.

The rake ſhould alſo be hung ſo far backwarder, that when it is fallen, the arms of it may lie in the ſame plane, or parallel, with the directors, on which it comes up (which will require the frame to be two inches longer in the model.) This will cauſe the rake to fall heavier, and drive the teeth into the roots, and bring them up without

without ſhattering. Theſe teeth muſt be made of ſteel, very fine, and ſo long as to reach down to the plank on which the directors are fixed, that is to ſay, ſix inches long (the directors are alſo to be made ſix inches broad above the plank.) The rake-head ſhould alſo fall a little before the crank is at its extremity, which will cauſe the rake to puſh forward to let the teeth come into the roots. The rake-teeth muſt drop in the ſame plane with the roller and wheels, or on the ſurface of the earth. No more ſpace ſhould be given from the roller C, to the long teeth, at G, G, than that the rake may juſt miſs the ſpikes of the roller C, and fall on the places before mentioned.

As the firſt roller B, was intended to cleanſe the ſecond C, more than any other uſe, it may be omitted when the machine is made in large, as Mr. Ogden has lately found that the long teeth at G, G, anſwer the end alone, and this renders the machine about a ſixth part ſhorter.

Now, to ſuit any ſort of earth, there ſhould be to each machine three planks, with directors at different ſpaces, to uſe occaſionally: in the firſt, the ſpaces between the directors ſhould be eight inches wide, in the ſecond ſix, and the third four. This will anſwer the ſame end as having ſo many machines.

As there may be ſome objections to the rake not leaving the roots when it has brought them up, Mr. Ogden has ſeveral methods of cleanſing it; but as he would make it as ſimple as poſſible, he chuſes to let it be without them at preſent: but ſuppoſe it ſhould bring ſome roots back again with it, it will probably loſe them before it gets back to the extremity; whence they will lie light, and be of but little detriment to the others coming up.

Mr. Ogden would have the firſt machine made four feet ſix inches wide, the teeth divided into equal ſpaces, the outſides into half ſpaces.

FAN, an inſtrument for winnowing corn. *See the article* WINNOWING.

FANTOME CORN, thin, or light corn, that which has but little bulk or ſolidity.

FARCY, or *Farcin*, a diſtemper to which horſes are too often ſubject. It is a diſeaſe of the blood veſſels, generally following the courſe of the veins, and, when inveterate, thickens their coat and integuments.

At firſt one or more ſmall ſwellings, or round buds like grapes or berries, ſpring out over the veins, and are often exquiſitely painful to the touch; in the beginning they are hard, but ſoon turn into ſoft bliſters, which, when broke, diſcharge an oily or bloody ichor, and turns into very foul and ill-diſpoſed ulcers. In ſome horſes it appears on the head only; in ſome on the external jugular; in others on the plate-vein, and runs downwards on the inſide of the fore-arm towards the knee, and very often upwards towards the briſket; in ſome the farcy ſhews itſelf on the hind parts, about the paſterns, and along the large veins on the inſide of the thigh, riſing upwards into the groin, and towards the ſheath; and ſometimes the farcy makes its appearance on the flanks, and ſpreads by degrees towards the lower belly, where it often becomes very troubleſome.

When the farcy appears on the head only, it is eaſily cured, eſpecially when it is ſeated in the cheeks and forehead, the blood-veſſels being here ſmall; but it is more difficult when it affects the lips, the noſtrils, the eyes, and kernels under the jaws, and other ſoft and looſe parts, eſpecially if the neck-vein becomes chorded. When it begins on the outſide of the ſhoulder or hips, the cure is ſeldom difficult; but when the farcy ariſe on the plate-vein, and that vein ſwells much, and turns chorded, and the glands or kernels under the armpits are affected, it is hard to cure; but more ſo when the crural veins within-ſide of the thigh are chorded, and beſet with buds, which affect the kernels of the groin, and the cavernous body of the yard. When the farcy begins on the paſterns or lower limbs, it often becomes very uncertain, unleſs a timely ſtop is put to it; for the ſwelling in thoſe dependant parts grows ſo exceſſively large in ſome conſtitutions, and the limbs ſo much diſfigured thereby with foul ſores and callous ulcerations, that ſuch a horſe is ſeldom fit for any thing afterwards, but the meaneſt drudgery: but it is always a promiſing ſign, wherever the farcy happens to be ſituated, if it ſpreads no farther. It is uſual to affect only one ſide at a time, but when it paſſes over to the other, it ſhews great malignancy; when it ariſes on the ſpines, it is then for the moſt part dangerous, and is always more ſo to horſes that are fat and full of blood, than to thoſe that are in more moderate caſe. When the farcy is epidemical, as ſometimes happens, it riſes on ſeveral parts of the body at once, forms naſty foul ulcers, and makes a profuſe running of greeniſh bloody matter from both noſtrils; and ſoon ends in a miſerable rot.

From this deſcription of the farcy, it will appear how greatly thoſe may be diſappointed, who depend on ſome ſingle ſpecific drink or ball for a certain cure; for the ſymptoms are ſometimes ſo favourable, that it is eaſily conquered by a very ſimple management; and when it ariſes ſuperficially upon the ſmaller veſſels, it will often go off, with moderate labour, without any other means than bleeding. Such inſtances as theſe may eaſily give a reputation to things of no great efficacy, and bring them into eſteem: but whoever has acquired any true notion of the farcy, will know that this diſtemper is not to be conquered but by ſuch things as are fitly adapted to the various ſymptoms that occur in the different ſtages of it. To avoid therefore the perplexity that ariſes from the various complications ſo uſual in the farcy, we ſhall conſider it in its different ſtates, or degrees, viz. when it ſeizes only the ſmaller veſſels; when the larger veins are chorded, and the feet, paſterns, and flanks affected; and laſtly, when the farcy, beginning on one ſide only, breaks out on the other alſo, and affects the whole body.

When the farcy makes its firſt appearance on the head, it riſes on the cheeks and temples, and looks like a net-work, or ſmall creeping twigs full of berries. Sometimes it inflames the eye, and ſometimes little bliſters or buds run along the ſide of the noſe. It ariſes often on the outſide of the ſhoulder, running along the ſmall veins with heat and inflammation; and ſometimes a few ſmall buds appear near the withers, and on the outſide of the hip. In all theſe appearances, the diſeaſe being ſuperficial, and affecting only the ſmaller veſſels, is eaſily conquered by the following method, when taken in time; for the ſimpleſt farcy, if neglected, may degenerate into the worſt ſort.

This diſtemper then being of an inflammatory nature, and in a particular manner affecting the blood veſſels, muſt neceſſarily require large bleeding, particularly where the horſe happens to be fat and full of blood. This always checks the beginning of a farcy, but is of ſmall ſervice afterwards; and if a horſe is low in fleſh, the loſs of too much

much blood ſometimes proves injurious. After bleeding, let the horſe have four ounces of cream of tartar and lenitive electuary; which may be given every other day for a week, to cool the blood, and open the body; and then give nitre three ounces a day, for three weeks or a month; and anoint the buds and ſwellings with the following ointment twice a day.

"Take ointment of elder four ounces, oil of turpentine two ounces, ſugar of lead half an ounce, white vitriol powdered two drams; mix together in a gally-pot."

The buds ſometimes by this method are diſperſed, leaving only little bald ſpots, which the hair ſoon covers again. When they break and run, if the matter be thick and well digeſted, they will ſoon be well: but in order to confirm the cure, and to diſperſe ſome little lumps, which often remain for ſome time on the ſkin without hair, give the liver of antimony for a month; two ounces a day for a fortnight, and then one a day for the other fortnight; by following this method, a farcy which affects only the ſmall veſſels, may be ſtopped in a week or ten days, and ſoon after totally eradicated.

When the farcin affects the larger blood veſſels, the cure is more difficult; but let it always be attempted early: therefore, on the plate, thigh, or neck-veins appearing chorded, bleed immediately on the oppoſite ſide, and apply the following to the chorded vein.

"Take oil of turpentine in a pint bottle ſix ounces, oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by a little at a time, otherwiſe the bottle will burſt; when it has done ſmoaking, drop in more oil of vitriol, and ſo on till all is mixed."

This mixture is one of the beſt univerſals in a beginning farcy; but where it is ſeated in looſe fleſhy parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are neceſſary.

Rub the parts firſt with a woollen cloth; and then apply ſome of the mixture over the buds, and wherever there is any ſwelling, twice a day. Give the cooling phyſic every other day, and then three ounces of nitre every day for ſome time. This method muſt be continued till the buds digeſt, and the chord diſſolves; and when the ſores run plentifully, the matter digeſts well, and the lips and edges are no ways thick or callous, you may expect a ſpeedy recovery; yet to confirm the cure, and prevent a relapſe, give the liver of antimony or crude antimony, as before directed; and to heal the ſores and ſmooth the ſkin, dreſs with bees-wax and oil.

When the farcy begins on the flanks, or towards the lower belly, it often takes its riſe from a ſingle puncture of a ſharp ſpur. The pain and ſmarting is one ſure ſign to diſtinguiſh the farcy from common accidents: the ſtaring of the hair, which ſtands up like a tuft all round the buds or bliſters, and the matter that iſſues from the buds, which is always purulent, and of a clammy greaſy conſiſtence, are other certain ſigns. After bathing with the mixture above-mentioned till the ulcers are ſmooth and healing, ſhould the ſwelling not ſubſide, to prevent the ſpreading of the buds, and to diſperſe them, bathe with either of theſe mixtures as far as the center of the belly; and at the ſame time give a courſe of antimonials, as will preſently be preſcribed.

"Take ſpirits of wine four ounces, oil of vitriol and turpentine of each two ounces, white wine vinegar or verjuice, ſix ounces."

Or take the follwoing:

"Take ſpirits of wine rectified four ounces, camphor half an ounce, vinegar or verjuice ſix ounces, white vitriol, diſſolved in four ounces of ſpring water, one ounce; mixed together."

In the lower limbs the farcy lies ſometimes concealed for a great while, and makes ſo ſlow a progreſs, that it is often miſtaken for greaſe, or for a blow or kick; and goes by the general appellation of a humour ſettled there. In order to diſtinguiſh one from the other, we ſhall obſerve that a kick, or bruiſe, is generally attended with a ſudden ſwelling, or a contuſed wound, which for the moſt part digeſts eaſily; the greaſe is alſo a ſmooth ſwelling that breaks out above the bending of the paſterns backwards; but the farcy begins on the paſtern-joint uſually with one bud, and runs upwards like a knotty crab-tree.

Very ſimple means has ſometimes ſtopped it, before it has began to ſpread; a poultice with bran and verjuice bound round the part, and renewed once a day, will often alone ſucceed; and if proud fleſh ſhould ariſe, touch it with oil of vitriol, or aqua-fortis, an hour before you apply the poultice; for when the diſtemper is local, as we ſuppoſe it here, it is to be conquered by outward applications.

When the diſtemper grows inveterate, and reſiſts the above method, and the veſſels continue chorded, Gibſon recommends the following mixture:

"Take linſeed oil half a pint; oil of turpentine and nitre, of each three ounces; tincture of euphorbium and hellebore, of each two drams; the ſoldiers ointment, two ounces, or oil of bays; oil of origanum, half an ounce; double aqua-fortis, half an ounce. After the ebullition is over, add two ounces of Barbadoes tar."

Rub this into the chorded veins, and wherever there is a ſwelling, once in two or three days; but if the orifices are choaked up with proud fleſh, or the ſkin ſo much thickened over the ulcers as to confine the matter, in either caſe it is neceſſary to make an open paſſage with a ſmall hot iron, and deſtroy the proud fleſh, after which it may be kept down by touching with oil of vitriol, aqua-fortis or butter of antimony. A ſalve may alſo be prepared with quick-ſilver and aqua-fortis, rubbing any quantity of the former with enough of the latter, to the conſiſtence of a liniment; ſmear the ulcers with this whenever they appear foul, and you will find it preferable to moſt other eating ingredients.

Our farriers after opening the buds, put in uſually a ſmall quantity of corroſive ſublimate or arſenic, which they call coring out the farcy; this may anſwer where the buds are few, and not ſituated near large blood veſſels, joints, or tendons: others uſe Roman vitriol, or ſublimate and vitriol, in equal quantities: but let it be remembered, that many a horſe has been poiſoned by theſe medicines ignorantly uſed, and in too large quantities; which ſhould be a caution to huntſmen not to ſuffer their hounds to feed on the carcaſes of farcied horſes, as the greateſt part of a pack have been poiſoned by that means.

I ſhall now mention ſome of the deſparate methods, and more violent kinds of medicines given by ſome internally: thus from four to eight ounces of lapis calimaris, to which two ounces of tutty, finely powdered, is added, with other metallic ſubſtances have been given. Some give a pound of barrel ſoap boiled in ſtale beer; with ſavin, rue, and other herbs of that intention: others go yet further, being determined to kill or cure, by giving drinks prepared with green vitriol, roche-allum, Roman

vitriol

vitriol, oil of vitriol, boiled in chamber-lie, with hempſeed, hemlock, and common ſalt. Thoſe who uſe nothing but the decoctions or juices of herbs, ſuch as wormwood, rue, or elder particularly, ſtand a much better chance for a cure, if given in time; but when the diſtemper is grown inveterate, nothing comes in competition with mercurial and antimonial medicines.

The following balls are proper in every ſtate of the farcy: and when the diſtemper has been in its infancy, before the ſkin was much defaced, has often cured it in a week or two, by giving them only once or twice a day: but in an old farcy, they ſhould be given for two or three months together.

"Take of native cinnabar, or cinnabar of antimony, eight ounces; long birthwort, and gum-guaiacum powdered, of each four ounces: make into a paſte with honey, and form into balls of the ſize of a large walnut, and roll them into liquorice powder."

The tedioufneſs of this courſe has encouraged the giving of mercurials, and indeed, where they are directed with ſkill, they muſt be attended with ſucceſs; the ſtronger preparations, as the red and white precipitates, and turbith, being combined with ſharp ſaline parts, may be hazardous and injurious, but the latter given in ſmall quantities have been found very ſucceſsful in ſuch kind of inveterate diſorders. Mr. Gibſon ſays, he has given it to a dram at a doſe, where the limbs have been greatly ſwelled; that in forty-eight hours the ſores were all dried up, and the limbs reduced; but that it made the horſe ſo violently ſick for ſeveral days, and ſcoured him to ſuch a degree, that it could not be repeated.

One would have thought, that the ſucceſs attending this medicine ſo ſuddenly might have encouraged Gibſon to have made further trials in ſmaller quantities; which, had he done, it is more than probable, he would not have been diſappointed: for the grand ſecret in giving mercurials, as alteratives, is the introducing them into the blood, without operating on the ſtomach and bowels; and to do this effectually, they muſt be given in ſmall quantities, and ſo bridled, as to controul their force on the firſt paſſages: taken in this manner, they will mix gradually with the blood and juices, and operate both effectually and ſafely.

The method I would recommend is as follows: give one ſcruple, or half a dram of turbith, mixed into a ball, with an ounce of Venice ſoap, every other night for a fortnight; then abſtain a week or ten days, and repeat it again. Should this ball purge, or make the horſe ſick, mix it up with two drams of philonium, or with four or five grains of opium, or camphor; with theſe reſtrictions, it may be given for ſome weeks; but ſhould the horſe's mouth be found tender or ſore, you muſt refrain giving, till that complaint is removed by gentle purges; and then return to it again in ſmall quantities; for as the effects of mercurials are very different in the different conſtitutions, both of horſes, as well as men, ſo the quantity muſt be varied in proportion to the operation, which is not intended here to be ſenſible, but to work imperceptibly on the blood and juices, correcting them as a powerful alterative. During the whole courſe, particular care ſhould be taken that he gets no cold.

Two ounces of quickſilver, divided with an ounce of turpentine, and made up into four balls, with diapente, and gum guaiacum, of each two ounces, and a ſufficient quantity of honey, have, for this purpoſe, been ſucceſsfully given, one ball twice a week; but gentle purgatives ſhould be interpoſed, to prevent a ſalivation, which ſome horſes are very prone to, on taking mercurials, though in ſmall quantities.

Dr. Brachen recommends the knots and chords to be rubbed with the mercurial ointment before they break, in order to diſperſe them, and, after breaking, to dreſs the ſores with equal parts of Venice turpentine and quickſilver: if by theſe means the mouth ſhould become ſore, treat as above. This method ſeems to be effectual with proper care.

The following is alſo recommended by the ſame gentleman.

"Take butter of antimony, and bezoar mineral, of each an ounce, beat up with half a pound of cordial ball, and give the bigneſs of a walnut, or three quarters of an ounce every day, for two or three weeks, faſting two or three hours after it."

As moſt preparations from antimony are of uſe in the farcy, ſo from two drams of antihecticum poterii to half an ounce, may be given with a bit of cordial ball every other day, for ſome time; for in theſe obſtinate caſes the very craſis of the blood muſt be altered, which can only be affected by degrees, and of courſe is a work of time. *Bartlet's Farriery, pag.* 178.

Water-FARCY. *See the article* WATER-FARCY.

FARDING-BAG, the firſt ſtomach of a cow, or any other ruminating animal.

FARE *of pigs*, the number a ſow bringeth at one time.

FARM, a portion of ground cultivated either by the owner or a tenant.

The ancient writers on huſbandry, who lived in warm countries, where the heat and moiſture of the air had ſenſible and frequently very dangerous effects on the health of the inhabitants, were very particular in their directions, for the choice of farms or eſtates, and of the ſpots whereon houſes ſhould be built, ſo as to avoid the inconveniencies ariſing from the climate, or from the quality or ſituation of the ground.

Though the temperate air which we enjoy in this iſland renders ſuch directions leſs neceſſary here, yet as ſeveral places in it are remarkably ſickly, and as, even in the moſt healthy ſituations, many houſes and villages are built on the leaſt healthy ſpots, it muſt be of conſiderable advantage to thoſe who can make their choice, to know what ſoils and places ought to be avoided; and of ſuch as are already fixed, to be acquainted with the means of correcting thoſe inconveniencies which cannot be totally remedied.

Inſtructions of this kind are now full as neceſſary in our language, as they ever were in the Greek or Latin, the countries in which Engliſh is ſpoken being more extenſive, and more various in their climes, than even the Roman empire ever was.

The ſacrifices of the ancient Romans ſhew how attentive they were even in the choice of the ground they encamped upon: much more were they ſo in that of the ſituation and nature of the place where they laid the foundations of more laſting buildings. They examined the livers of the cattle fed on the ſpot, when they offered them in ſacrifice; and if theſe were livid or corrupted, they offered others, as the unſoundneſs of the firſt might be owing to ſome caſual diſtemper: but if they were often found to be morbid, they concluded that the air, water, or food

which the place yielded, would have a like effect on human bodies, and therefore ſpeedily left that ground, to ſearch for a better ſituation. If after repeated trials, they found the livers good, they judged the air and food to be ſo likewiſe, and ſettled accordingly. We may ſtill obſerve the good effect of this precaution, in the healthy ſituations of the remains of Roman encampments: for they preferred health to every other conſideration.

The Romans had pleaſure as well as profit, in view, when they bought or ſtocked a farm; and therefore they laid it down as a rule, that no degree of fertility ſhould tempt a man to purchaſe in an unhealthy country, nor the pleaſanteſt ſituation in a barren one. "Buy not too haſtily," ſaid the wiſe Cato, "but view again and again the purchaſe you intend to make; for if it be a good one, the oftener you ſee it, the better it will pleaſe you. Examine how the neighbouring inhabitants fare. Let the country it lies in be a good one; the ways to and from it good; and the air temperate. Let your land, if you can chooſe your ſituation, be at the foot of a hill, facing the ſouth, in a healthy place, where a ſufficiency of labourers, of cattle, and of water may be had. Let it be near a flouriſhing town, the ſea, or a navigable river; or bordering upon a good and well frequented road. Let the buildings upon your ground be ſtrong and ſubſtantial. Do not raſhly condemn the methods of others. It is beſt to purchaſe from a good huſbandman, and a good improver."

Beſides the healthfulneſs of the ſituation, three other things ſhould be particularly attended to in the choice of a farm or eſtate; theſe are the air, the water, and the ſoil. The air ſhould be pure, and temperate; the water wholſome, and eaſily come at, and the ſoil rich.

The knowledge of the healthineſs of the air, is, as lord Bacon obſerves, diſcoverable rather by experiment than by reaſon or conjecture.

To examine the moiſture of the air before a houſe is built, wool, or a ſponge, may be hung up in the place, and afterwards compared with ſome of the ſame, expoſed in the ſame manner, and at the ſame time, in another place. According as they gain more or leſs in weight, the air is more or leſs humid.

The air is liable to greater alterations, from heat and cold, in ſome places than in others; and as that inequality in the air is an enemy to health, the moſt equal ſhould be choſen. This is eaſily determined by the thermometer, and by viewing the ſituation of the place; for the intermixture of hills and vallies, though pleaſing to the eye, may be held ſuſpected as to the lengthening of life, becauſe of the variations of heat and cold.

Open places and champaign countries are judged to be healthy, where the ſoil is dry, not parched or ſandy, where wild thyme and other aromatic plants grow ſpontaneouſly, and which is not otherwiſe bare, but interſperſed with trees for ſhade. Yet the change of air in travelling, after being accuſtomed to it, is healthy: whence many travellers have proved long lived; as, indeed, have alſo ſuch as have dwelt conſtantly in the ſame cottage. A ruddy complexion, clear white of the eye, quick hearing, and diſtinct voice, are ſet down by Palladius, as marks of the healthfulneſs of the place where theſe circumſtances are met with in the generality of its inhabitants.

The antients are particularly attentive to the quality of their water, and to the eaſe of coming at it. They adviſed bringing into the farm-houſe the water of a ſpring which never dries up; or, if there be no ſuch ſpring within the farm, to bring running water as near to it as may be; or to dig for well-water, not of a bitter or brackiſh taſte. If neither of theſe was to be found, they directed large ciſterns to be provided for men, and ponds for collecting and retaining rain water for cattle. They eſteemed that running water to be beſt for drinking, which had its ſource in a hill; ſpring, or well-water, from a riſing ground, was deemed the next beſt: well-water in the bottom of a valley was held to be ſuſpicious; and marſhy or fenny water, which creeps ſlowly on, was by them rightly looked upon as the worſt of all.

That water is known to be wholeſome, which has no mineral in it, is perfectly clear, has no taſte or ſmell, depoſits no ſlimy ſediment, leaves no ſpots, or incruſtation when boiled in copper or braſs veſſels, and which boils pulſe in a very little time. "Rain water, ſays Sir Thomas Elliot in his Caſtle of Health, is the moſt ſubtile and pure of any other water. The next is that which iſſueth out of a ſpring facing the eaſt, and paſſeth ſwiftly among great ſtones and rocks. The third is of a clear river, which runneth on hard ſtones and pebbles. There be divers means to try which is the beſt water; for that which is lighteſt in poiſe or weight, is beſt; alſo that whereof cometh leaſt ſcum or froth when it doth boil; alſo that which will ſooneſt be hot. Moreover, dip linen cloths in ſundry waters, and afterwards lay them to dry; and that which is ſooneſt dry, the water wherein it was dipped, is moſt ſubtile."

As ſprings and well-water paſs through beds of ſand, gravel, or ſmall ſtones, theſe clear it of all impurities, unleſs there be mixed with them ſubſtances which are ſoluble in water. If any mineral is mixed with the water, it is unfit for the farmer's uſe. If it be hard, it is thereby rendered unfit for waſhing, and ſome other culinary uſes. This is the kind of water which gives fleſh boiled in it a red colour. But even the hardeſt water may be eaſily rendered perfectly ſoft, and fit for any uſe, by mixing with it a ſmall proportion of pot-aſh, fixed ſalt, or, for want of theſe, the aſhes of any burnt vegetables.

The animal and vegetable ſubſtances which are mixed with ſtagnating water putrify, and taint that water. This taint is moſt effectually carried off by boiling, during which all the putrid particles evaporate: and whatever elſe remains in it will ſubſide when it is cold. It may likewiſe be much mended by having air forced through it by means of Dr. Hales's ventilator; or it may be corrected by mixing with it acids, ſuch as vinegar, juice of ſour fruits, ſpirit of nitre, vitriol, &c.

When there is neither running nor ſpring water, artificial ſprings may be made in the manner thus pointed out by Lord Bacon, who does not indeed ſay that he had experienced it himſelf; but it has been repeatedly tried ſince his time, and found to anſwer very well. "Upon a hanging ground, where there is a quick fall of rain-water, lay a half trough of ſtone, of a good length, three or four feet deep in the ground, with one end upon the high ground, the other upon the low. Cover this trough with brakes, to a good thickneſs, caſt ſand upon the top of the brakes, and you will ſee, after ſome ſhowers are paſt, the lower end of the trough run like a ſpring of water." This will continue for a long time after the rain is paſt, "as if, ſays that great philoſopher, the water did multiply itſelf upon the air, by the help of the coldneſs and condenſation of the earth, and the conſort of the firſt water." A gentleman in France,

France, whoſe manſion ſtood on a height far from any water, was adviſed to make a long ditch, about a fathom deep, in the neighbouring higher grounds, and to fill it with ſand; he did ſo, and it continued to bring a plentiful ſupply of water, for all domeſtic purpoſes.

M. de la Hire obſerves, in the Memoirs of the Academy of Sciences for the year 1703, that rain-water which has been purified by paſſing through clean ſands, and is afterwards collected in ſubterranean reſervoirs, will keep a long while without becoming putrid. He thinks this water the beſt that can be made uſe of, either for drinking, or for other economical purpoſes, becauſe it is not impregnated with any mineral, as ſpring waters ſometimes are. The only thing requiſite in the conſtruction of ſuch reſervoirs or ciſterns is, to have a place which will hold water, made of ſuch materials as will not communicate any bad quality to the water, which is to remain there a conſiderable time. The firſt water that falls from the roofs of houſes, when it begins to rain, ſhould be thrown away; as having ſerved only to waſh the roof, which, in dry weather, is always covered with dung of birds, and other filth. He rejects ſnow water for the ſame reaſon; and likewiſe the water of rain brought by winds which paſs over places infected with ill ſmells, as large cities, ſinks, &c. He computes, that water enough for the uſe of any family runs off the roof of the houſe which is inhabited by that family.

The buildings on the farm ſhould be proportioned to the produce, eſpecially as to ſtore-rooms. The expence of building ſhould be ſuch, as that, in caſe of accidents, one, or at moſt, two years rent may repair them. The farm-houſe ſhould be ſomewhat elegant, to give pleaſure to its poſſeſſors, and, as Columella adds, to allure the wife to take delight in it. It ſhould be built on the moſt healthy ſpot of the farm, in a temperate air, ſuch as the middle of a hill commonly enjoys, where it is neither ſtifling in the ſummer, nor expoſed to the rage of winds and ſtorms in the winter. It may be ſeated near a quick running river, if the banks are high, and the channel clear of mud: but if the river is large, care muſt be taken to ſituate it ſo that the winds may carry off the vapours in ſummer, and the fogs in winter, which otherwiſe would prove hurtful to the health of men and cattle. The front of the houſe ſhould be turned from ſuch a river. In a healthy ſituation, a houſe ſhould front the ſouth-eaſt, which is ſhaded during the hotteſt part of the day in ſummer, and enjoys the morning ſun in winter. A houſe facing weſterly will have the morning fogs longer retained, and will be too much heated by the afternoon ſun. In an unhealthy ſituation, the front ſhould be turned toward the north.

In ſouthern climates, where the ſun is within a few degrees of being vertical in ſummer, and yet the country is ſubject to ſevere cold in the winter, as is the caſe of ſome of our North American colonies, a ſouth front is rather convenient: for in the heat of ſummer, the ſun, being high, paſſes over the roof from the eaſt ſide to the weſt, and ſhines but little, or not at all, in at the front windows, and very weakly, becauſe obliquely, upon the front wall. But in the winter, being low, it ſhines full in at theſe windows, at a time when the cold renders its cheering preſence quite agreeable.

Places in this kingdom intended for defence, before the invention of cannon, were built either on riſing grounds difficult of acceſs, or where they could eaſily be ſecured by moats filled with water. Villages and farm-houſes were moſt frequently built in vallies, that they might be ſheltered from ſtormy winds; or near brooks or rivers, for the conveniency of water. In general, every means have not been uſed to provide againſt the inconveniencies of theſe ſituations: though as Mr. Worlidge obſerves, "were we for the future but duly to obſerve the beſt ſituations of places, and the compleateſt methods of building, in ſuch houſes as may hereafter be raiſed, our England would in a few years appear a kingdom beſet and adorned with curious and admirable habitations, poſſeſſed by noble and ingenious inhabitants."

Houſes built on too lofty a ſituation are expoſed to the violence of the winter's ſtorms, and to the ſcorching drought of the ſummer: yet we too generally find them without the only ſhelter their ſituation admits of, which is wood. The reaſon of this ſeems to be, that the inhabitants, finding that trees do not thrive well when they are firſt planted on dry heights, are at once diſcouraged. But where the plants are fenced from nipping winds while young, and protected from cattle till they become ſtrong, ſuch ground would be found abundantly favourable to the growth of trees which delight in a dry ſoil. "Theſe, as Mr. Worlidge expreſſes it, would yield a cooling, refreſhing, ſweet, and healthy air and ſhade during the heat of ſummer, and very much break the cold winds and tempeſts from every quarter in winter."

One might be apt to think from the unhealthineſs of low and fenny countries, that moats full of water about houſes ſhould be prejudicial to health: yet many facts ſhew the contrary. In Numb. 310, of the Philoſophical Tranſactions, a particular inſtance is given of two pariſhes which were ſurrounded with a moraſs, and yet were very healthy. Many houſes ſurrounded with moats are drier than others in a ſeemingly better ſituation; for books and furniture are often leſs apt to grow mouldy in the former, than in the latter. Hence it would ſeem probable, that the unhealthineſs of low marſhy countries muſt ariſe, rather from the putrefaction of animals and vegetables in ſlow moving or ſtagnating waters, than from a too great moiſture of the air, occaſioned by the quantity of water evaporated. Of this Dr. Pringle gives a remarkable inſtance in his judicious and uſeful Treatiſe on the Diſeaſes of the Army, when he ſays: "Another cauſe of the moiſture and corruption of the air were the inundations made about the fortified towns ſince the commencement of the war; which were particularly noxious upon letting the water off in the beginning of the ſummer, after the preliminary articles of the peace were ſigned. For theſe grounds, which were once entirely covered, being now half drained and marſhy, filled the air with moiſt and putrid exhalations. The ſtates being made ſenſible of this, by the ſickneſs that raged at Breda, and the neighbouring villages, gave orders to let in the water again, and keep it penned up till winter."

All phyſical writers point out the great danger to which health is expoſed from a moiſt and warm air; eſpecially if it be attended with a putrid vapour. Too much care cannot therefore be taken to guard againſt both. The too great moiſture may probably be prevented by collecting all the waſte water into deep ditches or ponds. We frequently ſee that ponds which have no ſupply of water but from rain, retain water during a very dry ſummer, when, according to the uſual calculations of evaporations, the whole muſt have diſappeared in half the time; from

whence it ſeems more than probable, that the quick evapo-ration of water, in ſome caſes, muſt ariſe from a heat reaching to, or affecting the earth under the water; and that, if care be taken to make the ditches or ponds ſo deep that the heat of the ſun ſhall not warm the earth at their bottom, the quantity evaporated will be but ſmall, and ſuch as will not be prejudicial to the health of the neighbouring inhabitants, if neither animal nor vegetative bodies are ſuffered to rot in them. The way to prevent this is by keeping the water free from graſs, or other impurities, which may give ſhelter to animals, whoſe rotting, as well as that of the graſs, or of thoſe impurities, communicates a putrid taint to the exhalations. It is in this caſe neceſſary, that the banks of ditches, or ponds, be ſloped as little as the ſtrength or ſtiffneſs of the earth will permit.

Though lofty and bleak ſituations are too often deſtitute of trees, villages built in vallies are as frequently too much crowded with them; which muſt be attended with the inconvenience of not having a free circulation of air, to carry off the moiſture ariſing from the earth, and perſpiring from ſo many trees. The antients would have built ſuch villages on riſing grounds, to avoid the too ſultry heat of the ſummer; or they would have preſerved a free circulation of the atmoſphere, to prevent the bad effects of a ſtagnating moiſt air.

On the firſt ſettlement of the Engliſh in North America, they imitated our cuſtom of building in vallies, and near rivers: but experience ſoon taught them, that ſuch places are more ſubject to the ſuffocating ſultry heat of the ſummer, and, what they little expected, to a greater ſeverity of froſt in the winter, than riſing grounds generally are. We have been informed by one of the moſt curious and intelligent obſervers of the laws of nature of perhaps any man on that continent, that the cold there, in their hardeſt froſts, is found to be ſo ſevere in the vallies, to a certain height, as ſometimes to kill every tender vegetable, while thoſe on the higher grounds eſcape. This generally takes place to a regular determined height, above which the Americans now build their houſes. If we be allowed to offer a conjecture concerning the cauſe of this, we ſhould ſay, that the effect of the cold ſeems to be limitted to the height to which the great moiſture of the air ariſes at that ſeaſon. In the hard winter of 1739-40, the ſame happened in this kingdom, when the froſt was much leſs ſevere in its effect in the hilly countries, than in the low lands.

Dr. Pringle, in his excellent treatiſe before-mentioned, points out the diſadvantages of planting ſo many trees as there generally are in moſt parts of the Netherlands. The ſame practice may be as juſtly blamed in many of the flat moiſt countries in England, eſpecially where they border on marſhes. Their ſpeedy growth tempts the inhabitants to plant, at the ſide of their ditches, willows and other trees, which delight in a moiſt ſoil; and theſe not only prevent a free circulation of air, but alſo perſpire a great deal of moiſture. Dr. Pringle confirms this by the following inſtances.

"At Eyndhoven, two battalions of the guards were quartered in the town, and the third lay without, in the peaſants houſes, all within the compaſs of a mile; yet, what was remarkable, this without the town had always three times more ſick in the returns, than either of the other two, notwithſtanding one of them had been very ſickly the year before in Zealand. Now, the height of the ground being alike in all, the difference in point of health could be aſcribed to nothing, but to the greater moiſture of the cottages; for in all other points, theſe corps were equal, as in diet, duty, and exerciſe. A ſimilar caſe occurred in the cantonment of a regiment of foot, whereof one company being quartered in houſes that ſtood upon a heath, enjoyed a tolerable degree of health, while the reſt that dwelt in a wood were remarkably ſickly. As a further proof how prejudicial it is to have the air confined by cloſe plantations in ſo moiſt a country, it was obſervable, that the Dutch camp at Gilſen, bordering on our cantonment, but lying on an open heath, preſerved a good ſhare of health, while we were at the worſt. It was not a little curious to obſerve, how the agues declined proportionably with the withering and falling of the leaf. At this time leſs moiſture aſcends, and by the ſhedding of the leaves villages come to be more open and perflated, and of courſe more dry and healthful. While the troops were very ſickly in Zealand, commodore Mitchel's ſquadron, which lay at this time at anchor in the channel, between South Beverland and the iſland of Walcheren, in both which places the diſtempers raged, was neither afflicted with fever or flux, but amidſt all that ſickneſs enjoyed perfect health: a proof that the moiſt and putrid air of the marſhes was diſſipated, or corrected, before it could reach them; and that a ſituation open to the winds is one of the beſt preſervatives againſt the maladies of a neighbouring low and marſhy country."

The drieſt ſpot in a low flat or fenny country ſhould be choſen for a dwelling place. Even where there is gravel or ſand on the ſurface, care ſhould be taken that the ſprings do not riſe high. Dr. Pringle points out the neceſſity of this caution, from what he obſerved in the lower parts of Brabant, "which is a barren ſand, where ſo little water is ſeen, that, at firſt ſight, the country is deemed dry and healthful: but the appearance is deceitful; for water is every where to be found at two or three feet from the ſurface: and in proportion to its diſtance from thence, the inhabitants are more or leſs free from diſeaſes."

Mr. Worlidge directs, that, in low moiſt grounds, cellars ſhould be made under the houſe, with good ceilings, or rather arched walls; for that this will conduce much to its dryneſs and healthfulneſs. The importance of rendering houſes dry appears in many inſtances mentioned by Dr. Pringle: but we ſhall give only that in his twelfth page. "One quarter of Ghent, called St. Peter's-hill, ſtands high above the reſt of the country; and in this the barracks, having drains and free air, were quite dry; ſo that the men who lay there enjoyed perfect health. But the reſt who were quartered in the low part of the town, where their barracks were moſtly the ground-floors of waſte houſes without drains, and of courſe very damp, were all ſickly."

The bed-chambers, in ſuch ſituation, more eſpecially, ſhould be in the drieſt and moſt elevated part of the houſe, and where the morning ſun may contribute moſt to keep them dry. If they are ſo ſituated, that the ſun does not warm and dry them, they ſhould be frequently aired with fires; the oftener in proportion to the greater dampneſs of the place: for this has been found to contribute greatly to the health of the inhabitants. We are informed by a gentleman who has experienced it in many inſtances, that, by this ſole precaution, he has preſerved ſeveral families from the ague, when that diſtemper was very epidemic in the neighbourhood. How much the dryneſs of bed-cham-

bers

bers contributes to health is confirmed by what Dr. Pringle obſerves to have happened at Bruges, where the ſoldiers that lay in the upper ſtories kept their health remarkably better than thoſe who were below on the ground floors.

As brick walls render houſes drier than thoſe of ſtone, and of a more equal warmth than plaiſtering, Mr. Worlidge directs, that, "where bricks can be had, the walls ſhould be built with them, as may be done for little coſt, if you raiſe firm and ſtrong columns at the corners of the houſe, and where it is neceſſary to ſupport the main beams. You may build theſe ſquare, and between them raiſe the walls with the ſame materials, and work them up together with the corners and columns, leaving one half of the extraordinary breadth of the column without, and the other within the walls, whereby you will ſave much charge in materials and workmanſhip, and yet your houſe will be firm and ſtrong."

We are too little attentive to the ſituation of houſes with regard to rivers; though a judicious choice in this muſt be of great conſequence to the health of the inhabitants. A quick flowing ſtream, with a clean channel and dry banks, will rather add to the beauty and healthineſs of a country: but oozy banks, over-run with reeds, or other ſtrong coarſe graſs, ſhould be carefully avoided, as being a ſhelter to all manner of putrid filth, whence unſalutary vapours muſt ariſe. It is a general opinion, that it is ſafer to dwell on the north than on the ſouth-ſide of a river; but experience ſeems to prove the contrary, eſpecially in warm climates. Marſhes, which are ſometimes overflowed with ſalt water, are found to be more unwholſome than freſh water marſhes. Their neighbourhood ſhould, therefore, be carefully avoided.

The Romans were univerſally agreed, that it was much better to occupy a ſmall farm than a large one; and laid it down as a rule, that the farmer ought to be ſtronger than the farm; becauſe in the ſtruggle which will ariſe between them, if the farm be too ſtrong for the farmer, he muſt be ruined; that is, if the extent of the farm be ſuch, that he cannot beſtow a due culture on every part of it, he muſt be a loſer: for, as Columella remarks, "it is certain, that a large tract of land, not rightly cultivated, will yield leſs than a ſmall ſpace well cultivated."

A judicious correſpondent of the editors of the Muſeum Ruſticum rightly obſerves, that the ſtocking of a farm is a point of great importance, and requires as much judgment and foreſight as any other point in huſbandry.

"The bad ſucceſs of great numbers, continues he, is owing to their not having a ſufficient ſum of money to begin with, which inevitably involves them in difficulties, and reduces their profit on every article of their produce. Their farm is underſtocked; they ſell at a conſtant diſadvantage; their fields are not half cultivated; and in a ſhort ſeries of years, unleſs ſome lucky hit ſets them up, they grow poor, in ſpite of all poſſible induſtry, judgment, and application.

"Even a low and eaſy rent will ſeldom remedy the want of mony at ſetting out.

"The want of judgment, in proportioning the quantity of each particular kind of ſtock to the quantity and nature of the lands of a farm, is alſo attended with great loſs.

"For inſtance if a farm requires four horſes, or two ploughs, and the farmer keeps only three, or a plough and a harrow, his field cannot be ſufficiently cultivated, even according to the ideas of culture common among farmers; and of courſe in a few years his lands muſt be in very bad order, to his great annual loſs.

"On the contrary, to overſtock himſelf with horſes, is to keep what will inevitably eat him out of houſe and home: expences attending them are very great, and if they are not kept conſtantly at work, their owner muſt neceſſarily loſe by them. But it will not be amiſs to explain myſelf more particularly on this head.

"I am ſpeaking at preſent of the practice of farmers, ſome of whom overſtock themſelves with horſes, without giving their lands extraordinary ſtirrings on that account. If a farm, which commonly requires three horſes, has four kept, and is conſequently ploughed and harrowed proportionably more, the farmer will be no loſer by his fourth horſe; but the caſe is very different when he is kept without being worked to the beſt advantage of the farm.

"It is not to be at once perceived how much is loſt by not having the number of horſes proportioned to the land; nor can this always be done.

"A farmer may find it neceſſary to keep four horſes, and when he has got them, it is a chance but he could perfectly well manage ſeveral fields more with them: and when a man has an opportunity of hiring additional fields, then ſhould his judgment come into play, to take no more than his old ſtock will manage to advantage, unleſs he has a ſum of money ready to make an addition to it.

"The ſame ill conſequences attend either over or underſtocking a farm with all other cattle: and it would be the farmer's advantage was he always to remember, that three beaſts, of any kind, well fed, pay better than four without their bellies full. On the contrary, not to keep the ſtock neceſſary, is to ſubmit to a conſtant loſs. Both theſe ſorts of conduct are frequently followed, to the great unprofitableneſs of farming.

"The proportion of the paſture and arable lands of a farm is of great conſequence towards the occupier's making a profit of his buſineſs.

"The unprofitable practice of ploughing up paſtures, and not laying them down again, which is ſo univerſal in this country among farmers, whenever their landlords will allow it, tends perpetually to impoveriſh them. They are all, to a man, mad after ploughed lands, and would willingly break up every acre of graſs in their farms.

"So general an opinion among them would make one think the practice really profitable; but the contrary appears beyond all contradiction to be the truth; I mean, according to the culture at preſent purſued in this country.

"Two thirds of the land of a farm in a rich country ſhould be graſs; and a little one had better all be ſo. The vaſt expences of the plough, without doubt, keep many farmers poor, who, if their farms were graſs, they would not run half the hazard, and enjoy a much better income.

"Particular points of bad management, for want of ſenſe or knowledge, thro' ſlovenlineſs, idleneſs, or other obſtructions, to any profitable huſbandry, are not what I mean to ſpeak of here, ſince they are ſo very various, and ſo totally ruinous, that no reaſoning can be concluſive, unleſs all ſuch exceptions are made.

"The improper quantity of land in a farm is often againſt the farmer's profit.

"Very large tracks, of two or three thouſand acres, which

which are common in Norfolk, are too extenſive for one farm. It is impoſſible for one man to cultivate ſuch a quantity of land well: much of it muſt be neglected, and but little perfectly managed.

" Great profit indeed ariſes from moſt of theſe farms; but they take a very large ſum of money to ſtock and manage them properly.

" Very ſmall ones, unleſs the farmer does the whole buſineſs himſelf, are equally liable to objection. The medium, which is ever, in proportion, the moſt profitable, is that quantity of land which will admit of being ſtocked and farmed without the want either of any addition or diminution. What I mean is this:

" Let us ſuppoſe a farm to conſiſt of ſeventy acres of land, twenty of them graſs and the reſt arable, in a rich country, the land from ten to ſixteen and ſeventeen ſhillings *per* acre; the occupier muſt keep one ſervant, and if he does not work hard himſelf, one labourer all the year, beſides ſome additional help at buſy times.

" I know there are many ſlovenly men, who cultivate (if their management deſerves that name) ſuch farms with fewer hands than I have mentioned; but their conduct can be no rule to good farmers. Four horſes are alſo neceſſary for ſuch a farm.

" Now, for the ſame ſtanding expences of ſervants wages, horſes, &c. the ſame number of ploughs, harrows, tumbrils, waggons, &c. &c. one hundred acres, or better, might be farmed with the ſame proportional profit: in this caſe, therefore, the tenant of ſeventy acres loſes conſiderably for want of thirty or forty more. Indeed we ſeldom meet with a farm nicely proportioned to the ſtock on it.

" There are many very evident reaſons why farming ſhould prove unprofitable to gentlemen who undertake to cultivate a part of their eſtates, whether for their amuſement or convenience, or, generally ſpeaking, even for profit.

" A very fine Norfolk farm, of a large extent of country, the rent exceeding low, and a gentleman willing to be at the expence of marling, in ſuch a caſe, there is no fear of a conſiderable profit, even without perpetual attention: but in common farms, in rich countries, no profit can ariſe to any gentleman that does not give the buſineſs conſtant attention, and deſcend to *minutiæ*; which may be too diſagreeable for him to ſubmit to.

" What I mean by profit, is not making the rent which he might receive from the tenant without trouble, and without hazard, but that additional ſum which is the farmer's profit after his rent and all expences are paid. This is ſcarcely ever made by gentlemen, who farm either for convenience or amuſement; and, excepting graſs grounds, I am perſuaded they loſe conſiderably by keeping land in their hands. The plea of growing enough for family uſe of wheat, oats, &c. is a miſtaken one; they had better by far buy every article, than have any thing to do with the plough.

" When I am told that farming anſwers to gentlemen, who I know do not give the farmer's attention to the buſineſs, I never believe it, or, at leaſt, am perſuaded that no regular accounts are kept. It will not be difficult to produce ſome good reaſons for this incredulity.

" It ſhould be remembered, that the farms which gentlemen keep in their own hands are ſeldom above fifty, ſixty, ſeventy, or an hundred a year, and not often ſo much. It is no eaſy matter for a farmer, with induſtry, ſobriety, and application, to make above a rent profit in ſuch a farm; and I believe but ſeldom ſo much. This is with every advantage of underſtanding his buſineſs, applying cloſe to it, and doing ſome work (if his farm is ſmall, a great deal) himſelf: how unlikely is it therefore that a gentleman, who may probably want theſe advantages, ſhould make near that profit, or, indeed, any at all!

" In the firſt place, a principal part of his buſineſs, his buying and ſelling, is tranſacted by his bailiff, or head ſervant, who muſt be paid for his trouble. He may be lucky enough to meet with an honeſt one; but I would never adviſe any one to let the profit of his farming depend on the honeſty of other people. Suſpicion, to the open generous mind, is irkſome and grating: but the farmer ſhould ſet out with the maxim of Deſcartes—to doubt of his very exiſtence, and ſuppoſe every man a knave till he finds him honeſt.

" But there are many inconveniencies, beſides theſe, in truſting to bailiffs.

" The gentleman we muſt certainly ſuppoſe to be ignorant of farming; and he is then, of courſe, in danger of having an ignorant ſervant, without the ability of detecting him. However, the ſingle expence of a bailiff, or a head ſervant, which are much the ſame, is too great to be kept conſtantly for a ſmall farm; and in their abſence the gentleman muſt depend on himſelf.

" This is palpably no dependence at all; for can it be expected that he will forego his diverſions, his excurſions of pleaſure, the company of his friends, the joys of ſociety, to attend to his farm? I could almoſt as ſoon believe, that his wife would renounce an opera or a ball for the pleaſure of dancing attendance on her butter and cheeſe in the dairy. The rural joys of romance are pretty much out of date now; and, alas! there is a great difference between the employment of a farmer's wife in England, and keeping ſheep in the plains of Arcadia.

" But to return:

" There are, even in a ſmall farm, a thouſand objects which require conſtant attendance.

" Cattle of no kind will thrive but in the maſter's eye: every variation of the ſeaſon to be remarked; the lucky moment for ploughing, harrowing, ſowing, reaping, &c. to be caught, and uſed with diligence and foreſight; fence for ever to be attended to; and, in ſhort, a million of other things, which require conſtant thought and endleſs application.

" That ſingle article, the employment of labourers, will alone run away with the profit of the whole farm.

" But ſurely it appears plainly, from what I have ſaid, that the unprofitableneſs of farming is ſcarcely ever owing to the art itſelf, but to the miſtakes of thoſe who practiſe it.

" As I have been ſo particular in diſtinguiſhing ſeveral points by which the followers of it loſe, I ſhall now treſpaſs a little longer on your patience, and give my ſentiments on the cuſtom of gentlemen's farming, in other reſpects than that of profit, to thoſe who are not ſolicitous about it, and in relation to it, to thoſe whoſe fortunes will not allow an indifference to ſuch a point.

" It is ſcarcely poſſible for a gentleman to live in the country without finding many inconveniencies in not keeping a team of farming horſes, with waggons, carts, &c. and other implements uſed in the buſineſs of huſbandry. While profit is not conſidered, there will flow a multitude of agreeable circumſtances from farming, which will have ſome relation to almoſt every particular of a country life.

" In

" In reſpect of entertainment, what more rational, or more amuſing, than country buſineſs, without the anxiety of caring for profit! The public good calls loudly to all gentlemen to keep ſome land in their hands, that experiments may be made, and modes of agriculture purſued, different from the practice of the neighbourhood, for the farmers, at leaſt, to ſee that their own cuſtoms are not the only good ones, and that there are improvements to be made even on their practice.

" All the improvements and new inventions in agriculture come from gentlemen; ſcarcely one, that I ever heard of is known to have been diſcovered by farmers.

" I do not wonder at this, for I think it is natural enough; but at the ſame time, it is a ſtrong reaſon for gentlemen's farming, whether they make profit by it or not. The expenſive uſe of manures, and introducing a garden culture into the field-huſbandry, were the effects, among a hundred other inſtances, of gentlemen's farming.

" But if the public good was not to be conſidered, yet the mere amuſement of farming to a gentleman of fortune, who has the leaſt taſte for country buſineſs, muſt plead warmly for its practice. Such farmers ſoon make a garden of their eſtates, at the ſame time that they improve the value of them.

" What can be more amuſing than experimental agriculture? trying the cultivation of the new-diſcovered vegetables, and all the modes of raiſing the old ones; bringing the earth to the fineſt pitch of fertility, and growing plants infinitely more vigorous and beautiful than any in the common tillage; uſing the variety of new machines perpetually invented, and obſerving their effects; and, in a ſmall extent of ground, ſee the growth of an infinite variety of vegetables, unknown in the common practice; perpetually enjoying the neatneſs of huſbandry, that *ſimplex munditiis* of farming, which gives the moſt beautiful colouring to every object around, and pleaſes the refined imagination with the enchanting proſpect of all the elegance of nature.

" Thoſe gentlemen of ſmall fortunes, who, if they practice any thing of farming, find it neceſſary not to be indifferent to profit, have many points to conſider.

" Such an one ſhould remember, that though a farm will afford amuſement, it will not yield profit without application. A conſtant attention to every article is highly neceſſary. He ſhould keep the exacteſt accounts, and make memorandums of what knowledge he can pick up. For a few years he muſt employ a bailiff; and he will find that every day and hour will increaſe his own knowledge, if he is attentive to buſineſs." *Muſeum Ruſticum, vol.* IV. *page* 264.

We ſhall conclude this article with the following

" *Prices of Implements of Huſbandry, Corn, and Farming-Work, in the North Part of Hertfordſhire, about Hitchin Baldock, and Stevenage.*

A waggon complete, from 16 to 20l.
A cart complete, from 8 to 10l.
A two-wheeled plough complete, with draught-chain, and ſplinter-bars, or whipple-trees, 3l.
A wheat two wheeled ſowing-plough, as the ſame wheels ſerve for both, 1l. 1s. 6d.
A foot, ſwing, or dray-plough complete, 1l.
A roller complete, 15s.
A five-barred harrow ditto, 17s.
A four-barred harrow ditto, 15s.
A three-barred harrow ditto, 12s.
Firſt ploughing per acre, 6s.
Second ploughing per acre, 5s.
Harrowing per acre, 6d.
Rolling per acre, 4d.
Hoeing turnips per acre, 4 to 5s.
Hockling, or cutting up and raking haulm, 2s. 6d. per acre.
A harveſt-man has per month from 33 to 40s. and his diet.
A ploughman, for a day's work, 8d.
A labourer, 1s. per day, and ſmall beer.
Price of threſhing per quarter, wheat 2s. barley 1s. oats 9d. peaſe 1s. 4d.
Price of horſes, from 5 to 15l.
Price of cows, from 3 to 8l.
Price of ſheep, from 10 to 20s.
Hogs, from 5 to 40s.
Wheat per load, 30 to 35s. Five buſhels make a load, and eight loads, or forty buſhels, a waggon-load.
Barley, 24s. per quarter.
Oats, 16s. per quarter.
Peaſe, 17s. per load.
Thetches, or vetches, 25s. per load.
Malt, 4s. 6d. per buſhel.
Note. Our buſhel is nine-gallon-meaſure.
Turnip-ſeed, 3d. per pound.
Red clover-ſeed, 4d. per pound.
Trefoil-ſeed, 2d. per pound.
Cinquefoil-ſeed, 4s. per buſhel.
Wheat-ſtraw, 10s. per load.
Barley and oat-ſtraw, 6s. per load.
Cinquefoil-hay, per hundred, 2s. 6d.
Clover-hay, per hundred, 2s. 6d.
Thatching per ſquare, yelming and ſerving included, 2s. 6d.
A carpenter per day, 1s. 8d.
A bricklayer ditto, 1s. 10d.
Brick at the kiln, 17s. per thouſand.
Plain tiles, 17s. per thouſand.
Pan-tiles, 10s. per hundred.
Lime, 6d. per buſhel.
Tiling-lath, 2s. 10d. per bunch.
Plaiſtering-lath, 1s. 5d. per bunch.
Hurdles per dozen, 8s.
Faggots, from 6 to 16s. per hundred.
Making, plaſhing, and laying live-hedges, and ditching, 4d. per pole of ſixteen feet and a half." *Muſeum Ruſticum, vol.* IV. *page* 78.

FARM-YARD, the place adjoining to the farm-houſe, where cattle are foddered, and ſeveral other neceſſary works, belonging to the farm, are performed.

FARTHING-DALE, or *farding-dale*, the fourth part of an acre of land, now generally called a rood.

FATHOM, a long-meaſure containing ſix feet.

FEABES, or *feaberries*, gooſeberries.

FEBRIFUGE, having the power of curing fevers. *See* FEVERS.

FEBRUARY, the ſecond month of the year.

This is a principal ſeed month for ſuch as they commonly call lenten grain, and is uſually ſubject to much rain or ſnow, which is not unſeaſonable.

Now ſow all ſorts of grey peaſe, fitches, beans, and black oats: in dry weather carry out dung, and ſpread it before

before the plough, and alſo on paſture ground; this being the principal month for that purpoſe.

This is a very proper time for planting trees and quick-ſets, and alſo to plaſh them; to ſet willows, plants, or pitchers, and alſo poplars, oziers, and other aquatics; and to lop trees, or cut coppices.

Sow muſtard-ſeed, and hemp-ſeed, if the ſpring prove mild: feed your ſwans, and make their neſts where the floods cannot reach them.

Soil ſuch meadows as you cannot overflow or water; catch moles, and take great care of ewes and lambs where they are forward. *Mortimer's Huſbandry, vol.* II. *p.* 413.

FEED, the quantity of oats, &c. given to a horſe or other animal.

FEEDING *of cattle. See the article* CATTLE.

FEET, the baſes or ſupports of an animal.

The knowledge of the feet is of the utmoſt importance in purchaſing a horſe. Nor is it enough that the creature have a well-proportioned foot; for if it chance to be thin or weak, the buyer will be diſappointed in his expectations; as ſuch a foot is liable to be ſpoiled in ſhoeing, by travelling on hard ſtony ground, by too much drought in hot ſeaſons, or by too much moiſture in winter. A thin foot is that where the cruſt or horn is thin. This may be very eaſily ſeen when the ſhoe is taken off, becauſe the verge all round the ſole will appear thin, and where it is ſo a horſe will winch with the leaſt touch of the pincers. The heel and frog are alſo apt to be ſoft and tender to the touch, and by reaſon of the weakneſs natural to ſuch a kind of foot, it often turns awry, and one point of the heel ſtands higher than the other.

FELL, the ſkin or hide of a beaſt.

FELLING, the act of cutting or hewing down.

When any tree is intended to be cut down for timber, the firſt thing to be taken care of is a ſkilful diſbranching, or lopping off, ſuch limbs, as may endanger it in its fall, many trees being annually ſpoiled for want of a previous care of this kind; and therefore in very large arms, chop a nick under them cloſe to the bole, and then meeting it with downright ſtrokes, it will be ſevered without ſplitting. Take care alſo to cut the tree as near the ground as poſſible, unleſs you deſign to grub them up, the doing of which will be of advantage both to the timber and to the wood; for timber is never ſo much valued, if it be known to grow out of old ſtocks.

M. de Buffon has very juſtly obſerved, that the trees intended to be felled for ſervice ſhould firſt be ſtripped round of their bark, and then ſuffered to ſtand and die upon the ſpot before they are cut. For by this means the ſappy part, or blea of the tree, becomes as hard and firm as the heart, and the real ſtrength and denſity of the wood has been proved, by many experiments, to be greatly increaſed by it.

FEN, a general name for boggy, mooriſh, or marſhy land, generally overflowed with water. *See the articles* BOG, DRAINING, MARSH, *and* MOOR.

FEN, is alſo the name of a very pernicious diſtemper to which hops are ſubject. It conſiſts of a quick growing mould, or moſs, which ſpreads itſelf with great rapidity, and occaſions dreadful ravages in the hop-grounds. *See the article* HOPS.

FENCE, a hedge, wall, ditch, bank, or other incloſure, made round fields, woods, gardens, &c.

No foreſt trees ſhould be admitted into the hedges that divide fields, as their ſhade, and wide extending roots, are found very injurious to corn, graſs, and even to the hedge itſelf. But in countries where inſtead of hedges, the fences are chiefly made of rough flakes of ſtone, piled dry every one upon another, or a little earth thrown in between them, to fill up the chaſms, a plantation of trees within theſe walls will hide their deformity, and give a warmth which cannot be expected from ſuch walls.

The moſt uſual way of incloſing land is with a ditch and a bank ſet with hawthorn, crabs, black thorn, holly, or white thorn, commonly called quick. Mr. Miller's inſtructions in this reſpect are very full, and contain among others, the following directions:

"It will be proper before planting to conſider the nature of the ſoil, and what ſorts of plants will thrive beſt in it; and alſo what the ſoil is from whence the plants are to be taken: for if the ground they are taken from be better than that into which they are to be put, it will be more difficult to make them grow. Thoſe which have been raiſed on the ſpot near the place where they are intended to be ſet, will always do beſt, if they are to be tranſplanted; and the next to them will be ſuch as are taken from a nurſery.

"I would recommend the white thorn, the black thorn, and the crab for outward fences to good ground: but I do not approve of intermixing them.

"The white thorn is the beſt quick to plant, becauſe it is the moſt eaſily procured, is very hardy and durable, and may be rendered the cloſeſt of any fence, by proper clipping. It, therefore, is preferred to all others for outward fences, or for the diviſion of fields, where they are expoſed to cattle, &c. It may be raiſed either from ſets or from ſeeds. The former is the moſt common way of propogating it: for the latter, which may very properly be ſown where the hedge is intended to ſtand, do not riſe till the ſecond ſpring. The white thorn will thrive on almoſt any well looſened ſoil, except the drieſt gravel or ſand.

"The black thorn and crab make very good fences, and are to be raiſed in the ſame manner as the white thorn: but if the kernels of apples or crabs be ſown, it is beſt to ſow the pomace with them; for they will then come up the ſooner, that is to ſay, the firſt year.

"The black thorn is not accounted ſo good for fences as the white thorn, becauſe it is apt to run more into the ground, and is leſs certain as to the growing: but on the other hand, its buſhes are much better, and more laſting, than thoſe of the white thorn, or indeed any other ſhrub, for dead hedges, or to mend gaps: nor are they ſubject to be cropt by cattle, as the others are. The richer the mould is, the better the black thorn will proſper: but it will grow on the ſame ſort of ſoil as the white thorn.

"The holly makes an excellent fence, and is preferable to all the reſt; but it is difficult to be made to grow at firſt, and is a ſlow grower. However, when it does grow, it makes amends by its height, ſtrength, and thickneſs. It delights moſt in ſtrong ground: but will grow upon the drieſt gravel, even among rocks and ſtones. It is raiſed from ſets, or berries, like the hawes of the white thorn, and lies till the ſecond ſpring before they come up. Theſe two are beſt ſown in the place where they are intended to ſtand. They ſhould be well weeded, both before they come up, and afterwards, till they are grown to ſuch a ſize, as, of themſelves, to kill the weeds.

"French furze will make good hedges upon dry ſandy banks, where few other plants will grow: but they muſt

muſt be kept very clean at the bottom, and never ſuffered to grow too high: nor ſhould they be clipped either in dry weather, late in autumn, or early in the ſpring; becauſe the cutting of them at thoſe ſeaſons is apt to make them die in patches, which is irrecoverable; as no new ſhoots will here ever proceed from the old wood.

"Alder planted on a bank, the ſide of which is waſhed by a river or ſtream, will make an extraordinary fence, and preſerve the bank from being undermined by the water; becauſe the alder is continually putting forth from the lower roots ſuckers, which are of great advantage where the current of the water waſhes away the earth.

"If there is to be a ditch along the hedge, that ditch ſhould be at leaſt ſix feet wide at top, three feet deep, and only one foot and a half over at the bottom, that each ſide may have a proper ſlope: for where its ſides are dug too perpendicular, they are very apt to fall in after a hard froſt, or heavy rain; and if the ditch is made narrower than here directed, it will ſoon be choaked up in autumn, by the falling leaves, and the growth of weeds: nor will it be a ſufficient defence for the hedge againſt cattle.

"When the bank at the ſide of this ditch is to be planted with quicks, the ſets ought to be about as thick as a gooſe quill, and their tops ſhould be cut off within four or five inches of the ground. They ſhould be freſh taken up, ſtrait, ſmooth, and well rooted. Part of the turf taken off the ſurface of the ground where the ditch is to be dug, ſhould be laid, with the graſſy ſide downward, on the ſide of the ditch, where the bank is intended to be made, and ſome of the beſt mould ſhould be laid upon it, to bed the quick. The ſets of quick, prepared as before directed, are then to be laid upon that mould, a foot aſunder, with their cut ends ſomewhat ſloping upward. When this firſt row of quick is thus laid, it muſt be covered with mould; ſome of the remaining turf muſt then be laid upon that mould with the graſs ſide downward, as before; and more mould muſt afterwards be laid upon this turf. When the bank has, by theſe means, been raiſed about a foot high, a ſecond row of ſets ſhould be laid in the ſpaces between the lower quick, and with their ends turned the oppoſite way, in order to thicken the bottom of the hedge. Theſe are then to be covered in the ſame manner as the former: the bank is to be topped with the bottom of the ditch: and a dry or dead hedge muſt be made on the other ſide, to defend the young plantation from cattle.

"To make theſe dead hedges, ſtakes ſhould be driven into the looſe earth, ſo low as to reach the firm ground. They ſhould be about two feet and a half aſunder. Oak ſtakes are reckoned the beſt, and black thorn and ſallow the next. When they are fixed, ſmall buſhes ſhould be laid at the bottom, but not too thick; for that would make the buſhes rot. The upper part of the hedge ſhould be laid with long buſhes, to bind the ſtakes in, by interweaving them: and, to render this hedge yet ſtronger, it may be eddered as it is called, that is, the tops of the ſtakes may be bound in on each ſide, with ſlender long poles or ſticks. When this eddering is finiſhed, the ſtakes ſhould be driven anew; becauſe the doing of that, together with the weaving of the hedge, will probably have looſened them.

"The quick muſt be kept conſtantly weeded, and ſecured from being cropped by cattle, and in February it ſhould be cut to within an inch of the ground; for this will make it ſhoot ſtrong, and greatly help its growth.

"When a hedge of this kind is about eight or nine years old, it will be proper to plaſh it; the beſt time for which is in October, or February.

"After it has ſtood twenty or thirty years, and there is in it old ſtubs, as well as new ſhoots, thoſe ſtubs ſhould be cut ſloping off within two or three inches of the ground, except the beſt and longeſt of the middle ſize, which ſhould be left to lay down, and ſome of the ſtrongeſt, which ſhould be cut off at the height of five or ſix feet, according to the intended height of the hedges. Theſe laſt may be left to ſerve inſtead of ſtakes, and freſh ſtakes ſhould be put wherever they are wanted. The hedge ſhould be thinned, ſo as to leave on the ſtubs only ſuch ſhoots as are deſigned to be of uſe, that there may be room left to put a ſpade in between them, in order to give the earth as good a ſtirring as poſſible. The ditch alſo ſhould be cleanſed, and its ſlopes carefully repaired; and where the earth has been waſhed from the roots of the quick, or is hollow, it ſhould be faced anew with ſo much of the firſt ſpit of earth as there is occaſion for. The ſecond ſpit of this earth ſhould be laid on the top of the bank: for if it be laid on the ſide, or face of the bank, it will ſlip again into the ditch when wet comes, and perhaps drag down a great deal of the bank.

"Two extremes are to be avoided in the plaſhing of quicks: the firſt is, the laying the plaſhes down too low, and too thick; becauſe that makes the ſap run wholly into the ſhoots, and leaves the plaſhes without nouriſhment, which, with the thickneſs of the hedge, kills them. The ſecond is, not to lay them too high; becauſe this draws all the ſap into the plaſhes, ſtints the ſhoots at the bottom, and renders the hedge ſo thin, that it will neither hinder cattle from going through, nor from cropping of it.

"When the ſhoot deſigned to be plaſhed is bent, give it a ſmall cut with a bill, half through, ſlanting a little downward; then weave it about the ſtakes, and trim off the ſmall ſuperfluous branches that ſtraggle too far out on either ſide of the hedge.

"If the ſtubs are very old, cut them quite down: ſecure the chaſms with a good dead hedge on each ſide, till the young ſhoots are got up tall enough to plaſh: and plant new ſets in the vacant ſpaces.

"If the bank for a fence be without a ditch, and it is intended to make a hedge of quicks, the ſets, prepared as before, ſhould be planted in two rows, almoſt perpendicular, at the diſtance of a foot from each other, in the quincunx order; ſo that, in effect, they will be only ſix inches aſunder." *Miller's Gard. Dict.*

When the plants of the thorn are themſelves ſtinted, or much decayed, as they generally are pretty ſoon, through the unmerciful wounds given them by unſkilful hedgers; inſtead of plaſhing them, the farmer's beſt way will be to dig them up, and plant young ſets in their ſtead. The only inconvenience attending this renewal is the expence of a dead hedge, which is not wanted in plaſhing; but I queſtion much, whether the healthineſs of the plants, when cut ſmooth, and in ſuch a manner as not to retain water, may not ſufficiently compenſate that charge. For the ſame reaſon, it ſeems to be moſt rational to cut the plaſhes upward; becauſe the wound will then be covered from the wet, at leaſt in ſome degree, by the ſlip which remains prominent over it.

Beſides the plants already mentioned for hedges, the ſweet-briar, or eglantine (dog-roſe) is thus recommended

by a correſpondent of the ſociety of improvers in the knowledge of agriculture in Scotland, who had tried in vain, in that country, all the methods of fencing uſually practiſed in Hampſhire and Eſſex.

"Obſerving that no creature eat up or deſtroyed the ſweet-briar or eglantine (dog-roſe) I gathered the hips of this plant, and laid them in a tub till March: the ſeeds then rubbed out eaſily, and I ſowed them in ground prepared for garden-peas. By this means I got my crop of peas without prejudice to my briars, which came up the next year; and the year after, when they were about a foot high, I planted them in the following manner.

"After marking out my ditch, I laid my plants about eighteen inches aſunder, upon the ſide graſs, and covered their roots with the firſt turfs that were taken off the ſurface of the intended ditch. The earth ſide of theſe turfs was placed next to thoſe roots, and upon the turfs was laid other earth, taken out of the ditch, which I then finiſhed. In four or five years, theſe plants made a fence which no ſheep, cattle, or horſes could paſs. If old briars are dug up, and divided, they make excellent plants. Where the fences are thin, they may be eaſily thickened, by laying down branches; for theſe will make ſhoots of ſix or ſeven feet in a year. They bear clipping very well.

"In ſandy places, I ſeldom care to throw all the earth out of the ditch at once, but wait a year, till what I had thrown up is ſettled and ſwarded a little: then I raiſe my bank to the intended height. In the mean time nothing hurts my briars; and in two or three years after they have been planted, nothing can paſs the fence. Sheep ſometimes attempt it: but they ſoon are ſo entangled, that they would lie there till they die, if they were not taken out."

In the hedges which divide the farmer's fields only, fruit trees may be planted; and theſe will yield profit, as well as ornament; or the fruit may be grafted upon a ſtock in the hedge, properly ſuited thereto.

Theſe ſtocks ſhould be pruned up every year, till they are brought out of the reach of cattle, and then they may be grafted with the red-ſtreak, gennetmoil, or any other fruit. If they have proceeded from apple-kernels, they may remain ungrafted, and will yield very good cyder fruit: but then it will be longer before they bear. Alſo, if the leaf, ſhoot, and bud of a natural ſtock, promiſe more than common, a trial may be made, whether that ſtock will not perhaps produce a fine new fruit; and if it be not liked afterwards, it may then be grafted.

Mr. Miller reckons the plants raiſed from the kernels of the ſmall wild crab much better for hedges, than thoſe which are raiſed from the kernels of any other ſort of apple; becauſe the former never ſhoot ſo ſtrong as the latter, and therefore may be better kept within the proper bounds of a hedge; and as they generally have more thorns upon them, they are better guarded againſt cattle.

Fences made in marſhy grounds require plants which delight in moiſt ſoils. Of this kind are, particularly, the black alder, the willow, and the poplar: the birch-tree, and the aſh will likewiſe grow very well in ſuch places: but the firſt of theſe, viz. the alder, is reckoned the beſt and moſt profitable.

It likes a ſoil ſo moiſt as few other trees will thrive in, and is propagated either by layers, or planting of truncheons about three feet in length. The beſt time for planting theſe laſt is in February, or the beginning of March, when they ſhould be ſharpened at their larger end, and the ground ſhould be well looſened before they are thruſt into it, leſt the bark ſhould be torn off, which may occaſion their miſcarriage. They ſhould be ſet at leaſt two feet deep, to prevent their being blown out of the ground by violent winds, after they have made ſtrong ſhoots, and they ſhould be kept clear from all ſuch weeds as grow tall, at leaſt till they have got good heads; after this, they will keep down the weeds, and require no farther care.

If alders are raiſed by laying down the branches, this ſhould be performed in October, and by the ſame time twelvemonth they will have roots ſufficient to be tranſplanted, which muſt be done by digging a hole, and looſening the earth in the place where each plant is to ſtand. The young ſets muſt be planted at leaſt a foot and a half deep, and their top ſhould be cut off to within about nine inches of the ground; for this will make them ſhoot out many branches.

The alder tree may be trained into very thick cloſe hedges, to the height of twenty feet and upwards. It will thrive exceedingly on the ſides of brooks, for it grows beſt when part of its roots are in the water, and may, if planted there, as is uſual for willows, to be cut for poles every fifth or ſixth year. Its wood makes excellent pipes and ſtaves; for it will laſt a long time under ground, or in water: and it is likewiſe much eſteemed by turners, plough wrights, &c. and for making ſeveral utenſils neceſſary in agriculture. Its bark yields a good black dye.

All the ſorts of willows, of which Mr. Miller enumerates fourteen, grow beſt in moiſt boggy land, and may be eaſily propagated by planting cuttings or ſets, either in the ſpring or autumn: for theſe readily take root, and are of quick growth.

In countries where there is great plenty of rough flat ſtones, the fences which bound an eſtate, or farm, are frequently made with them. It is a pretty common practice in Devonſhire and Cornwall, where they build as it were two walls with theſe ſtones laid one upon another, firſt two, and then one between; and as the walls riſe, they fill the intermediate ſpace with earth, beat the ſtones in flat to the ſides, which makes them lie very firm, and ſo proceed till the whole is brought to the intended height. They then plant upon theſe walls quick hedges, and even timber trees, which thrive exceedingly; and they eſteem theſe fences the beſt ſecurity that can be to their ground and cattle. However, if theſe ſtones are laid rough and dry, they cannot but be diſagreeable to the eye, and muſt certainly require frequent repairs, becauſe they will often be forced out of their places, or beaten down by cattle.

To prevent this, let ſuch walls be built in the bottom of a ditch, made wide enough for the purpoſe, and ſloped down on each ſide. The deformity will then be hid: and as the cattle cannot ſtand facing the wall, ſo as to attempt to leap over it, the ſtones of which it is compoſed will be the leſs liable to be beaten down. The earth taken out of the ditch may be ſpread on the adjacent ground, and its ſides may be planted with ſuch trees, or under-wood, as beſt ſuit the ſoil. If a ſpace of ſeveral feet, proportioned to the demand which there may be for timber, is left on the inſide of the fence, it will be attended with every advantage ariſing from a ſupply of that neceſſary commodity; without prejudice to the arable or more valuable paſture.

Another very ſtrong and durable fence may be formed thus, in graſſy places. Dig pieces of turf, four or five inches

inches thick, the breadth of your ſpade, and about a foot long. Lay theſe turfs even, by a line on one ſide, with the graſs outward, at the diſtance of ten or twelve inches within the mark at which the ditch, afterwards to be dug in the ſolid ground, is to begin. Then lay in the ſame manner, but with their graſs ſides turned out the contrary way, another row of turfs, at ſuch diſtance as to make a breadth of foundation proportioned to the intended height of the bank. The reaſon for placing theſe turfs thus much within what is to be the edge of the ſolid ground dug away on each ſide, is to prevent the bank from falling in, if the ground underneath it ſhould be any way defective. A ditch, of what breadth or depth you pleaſe, may then be dug; or the ground may be lowered on each ſide with a ſlope; in which laſt caſe there will be no loſs of paſture by the fence, becauſe it may be ſowed with hay ſeeds, and will bear graſs on both ſides. Part of the earth taken out of the ditches or ſlopes, will fill the chaſm between the rows of the turf, and the reſt may be ſcattered over the adjacent ground. Three, four, or more layers of turf may be thus placed upon one another, and the interval between them filled up as before, till the bank is brought to the deſired height; only obſerving to give each ſide of it a ſmall ſlope, for greater ſtrength. The top of this bank ſhould be about two feet and a half wide, and the whole of it ſhould be filled up with earth to a level with the turfs, excepting a little hollow in the middle, to retain ſome rain. Quick ſets ſhould then be planted along this top, and they will ſoon form an admirable hedge. By this means, a bank four feet high, and a ſlope only two feet deep, will make, beſides the hedge, a fence ſix feet high, through which no cattle will be able to force their way: for the roots of the graſs will bind the turfs ſo together, that, in one year's time, it will become entirely ſolid, not a joining will appear, nor a turf can be got out; and it will be yet much ſtronger, when the roots of the quick ſhall have ſhot out among it. The only precautions neceſſary to be obſerved here, are, firſt, not to make this bank when the ground is too dry; becauſe, if a great deal of wet ſhould ſuddenly follow, it will ſwell the earth ſo much, as, perhaps, to endanger the falling of ſome of the outſide, which, however, is eaſily remedied if it ſhould happen; and, ſecondly, if the ſlope be ſuch as ſheep can climb up, to ſecure the young quicks, at the time of planting them, by a ſmall dead hedge, either on or near the top, on both ſides. If any of the quicks ſhould die, which they will hardly be more apt to do here than elſewhere, unleſs, perhaps, in extreme dry ſeaſons, they may be renewed, as in other places, by planting new ones, or by layers from thoſe which remain.

A fence like this will do even for a park; eſpecially if poſts and rails, about two feet high, are placed a little ſloping over the ſide of the bank, on or near its top: for no deer will be able to jump over this, nor can they creep through it.

This is one of the beſt fences to afford ſhelter for cattle; and if the quick on the bank is kept well clipped, it will form a kind of green wall, pleaſing to the eye.

When the bounding fence is only to guard againſt accidents from without, it may be made in the ha-ha manner; only taking care that the earth be ſo well rammed down at the back of the wall, as that the ſtones may be properly ſupported, and bear equally.

The ingenious author of the Eſſays on Huſbandry recommends the horn-beam plant, as one of the beſt yet known for making fences, according to the method uſed in Germany, where ſuch fences are common.

"When the German huſbandman, ſays he, erects a fence of this nature, he throws up a parapet of earth, with a ditch on each ſide, and plants his horn-beam ſets in ſuch a manner, as that every two plants may be brought to interſect each other, in the form of St. Andrew's croſs. In that part where the two plants croſs each other, he gently ſcrapes off the bark, and binds them with ſtraw twhart-wiſe. Here the two plants conſolidate in a kind of indiſſoluble knot, and puſh from thence horizontal ſlanting ſhoots, which form a ſort of living paliſado, or *chevaux de friſe*; ſo that ſuch a protection may be called a rural fortification. The hedges, being pruned annually, and with diſcretion, will, in a few years, render the fence impenetrable in every part. *Eſſays on Huſbandry, eſſay* I. *page* 14.

FENNEL, the name of a well known plant cultivated in kitchen gardens. It is propagated by the ſeeds, which ripen in autumn, and ſhould be ſown ſoon after. They will come up in the ſpring, and require no other care than to keep them clean from weeds. This plant will grow in any ſoil or ſituation.

FENNY, mooriſh, marſhy, boggy.

FENNY-LAND. *See the articles* BOG MARSH, *and* MOOR.

FERMENT, the ſubſtance uſed to raiſe a fermentation, as yeaſt, wine, lees, leven, &c.

FERMENTATION, an inteſtine motion excited in vegetable ſubſtances, whereby the coheſion of their parts are deſtroyed, and may eaſily be ſeparated from one another.

In every fermenting liquor, an inteſtine motion is generated in all its parts. It is called inteſtine, becauſe it is excited by the internal principles contained in the vegetable juices; for vegetable juices or infuſions made in water, however bright at firſt, and apparently homogeneous, on being kept in a moderately warm place, in veſſels not cloſely ſtopped, become turbid, conceive an inteſtine motion, emit numerous air-bubbles, and diſcharge a pungent vapour of extreme ſubtilty.

All bodies which may be ſo changed by this inteſtine motion, as to produce wine, are ſaid to be fermentable: and as this was never found to happen in any other than vegetable ſubſtances, vegetables alone are ſaid to be fermentable.

The fermentable claſs of vegetables are extremely various, and might be diſtributed into as many claſſes, as they require different methods of fermenting. We ſhall, however, mention them no further than they relate to the pleaſure and profit of the huſbandman.

The firſt claſs of fermentable ſubſtances includes all the pulpous ſummer fruits, which, when ripe, abound with a tartiſh ſweet juice; ſuch as grapes, apples, pears, elderberries, gooſberries, raſberries, currants, cherries, plums, and all other ſummer fruits, provided they be kept free from a tendency to putrefaction.

The ſecond claſs contains the freſh expreſſed and native juice of plants, provided they be of a tartiſh and ſweetiſh taſte; ſuch as the juice of the ſugar-cane, of liquorice, and other ſimilar plants. To this claſs may be added all the juices which diſtill from certain trees when wounded, eſpecially in the ſpring; as the birch, the plane or maple, the vine, the walnut-tree, &c. The maple has this remarkable property, both in the ſmall kind and in the great, which is called the ſycamore, that, being tapped, it will

bleed freely in the winter, and its juice will flow very plentifully even after a hard froſt. All theſe juices generally run into a ſpontaneous fermentation.

The third claſs compriſes thoſe vegetable juices which are formed and inſpiſſated by nature into a certain ſaponaceous ſubſtance, conſiſting of ſaline and oily particles; ſuch as honey, manna, and all other juices which are not gummy or unctuous.

The fourth claſs comprehends all thoſe ſeeds which, when ripe and dry, may be ground into a fine meal, without their forming an unctuous paſte; ſuch are barley, wheat, oats, rye, &c.

Certain phyſical circumſtances are requiſite to render theſe different ſubſtances fit for fermentation; namely, firſt, a perfect degree of maturity ſuitable to each kind. All ſeeds and fruits which are ſo perfect, as, when ſown in fertile ground at a proper ſeaſon, and in a proper climate, to produce a plant of their own ſpecies, are fit for this operation. Another requiſite to fermentation is a moderate proportion of oil: for though fat ſubjects are more apt to grow rancid, than to ferment, yet if they are entirely deprived of their oils, they are hereby alſo rendered unfit for fermentation. Thus, bruiſed almonds, which are rich in oil, will ſcarcely ferment; but they may be ſo far freed from their oil by art, as to be made fitter for this purpoſe. Solubility in water is a third and principal requiſite in fermentable ſubjects.

The methods of preparing each fermentable ſubſtance for fermentation will be given under the articles *Wine*, *Cyder*, and *Beer*.

The juices of ſummer fruits are, of their own nature, greatly diſpoſed to ferment, ſo as immediately to begin this operation, without the addition of any other ferment. Other liquors may, however, ſtand in need of the help of other ferments, to begin this inteſtine motion, which, under proper conduct, proceeds afterwards of itſelf. The chief of theſe ferments is the recent flowers, commonly called yeaſt, thrown up to the top of beer in the act of fermentation: for if this rarified frothy matter be mixed with other fermentable liquors, it greatly promotes their fermentation. The ſame matter become heavier, and ſunk to the bottom, provided it be not too ſtale, ſtill retains the ſame vigour, though in a leſs degree than in its former ſtate. The remains of former fermenting liquors ſticking to the ſides of caſks, have the ſame effect: for caſks thoroughly penetrated by the ſubtilty of wines which they formerly contained, are extremely apt to raiſe a violent and quick fermentation in the freſh liquors put into them. Acid paſte of flour fermented, or bakers leaven, may all be employed for the ſame purpoſe: for though meal may be preſerved freſh and ſweet during years, if it be kept in a dry ſtate, and perfectly free from inſects; yet if it be wrought with water into a ſoft cloſe paſte, and lightly covered in a warm place, it will ſoon begin to heave, be all over full of cavities, change its ſmell, colour, and tenacity, prove acid both to taſte and ſmell; and thus become that proper ferment from which the whole of this operation firſt took its name. When thus prepared, if part of it be mixed with other paſte, freſh and not yet fermented, it will cauſe this to ferment much ſooner, and more ſtrongly, than it would otherwiſe do. Hence, we need not be ſolicitous about a firſt ferment, becauſe nature affords it ſpontaneouſly every where. The great promoters of all the ſtages of this proceſs are warmth, a moderate admiſſion of air, and the addition of actually fermenting matter.

If we take large glaſs bodies, place them upright where they may be kept in an equal heat, and then fill each of them three quarters full with a crude fermentable liquor well prepared for the operation, the orifice being ſlightly covered with a cloth, and a heat kept up to above ſixty degrees, it will be pleaſing to obſerve the ſeveral degrees of fermentation.

The maſs, at firſt reſting, and poſſeſſing a certain ſpace in the veſſel, gradually begins to ſwell, rarify, and conceive an inteſtine motion through its whole body, acting upwards, downwards, and ſideways, in ſtrange circumvolutions, without ceaſing, though with a different force. In the mean time bubbles are every moment formed in every part of the maſs, and conſtantly endeavour to riſe up to the ſurface, where they burſt with a hiſſing noiſe, or often break in the mid-way. Hence the whole maſs froths, diſcharging with an audible ebullition a certain tartiſh ſpirit, which proves acrimonious to the noſe, ſurpriſingly elaſtic, and capable of burſting almoſt any veſſel by its great expanſive force. If a large veſſel full of fermenting muſt, in the height of its action, ſhould diſcharge this condenſed ſpirit through a ſmall orifice, and a ſtrong healthy man ſhould draw in at his noſtrils the vapour ſo iſſuing, he would inſtantly fall down dead; or if he received but little thereof, he would become apoplectic, and remain an idiot his whole life. When this vapour is confined and accumulated in cloſe rooms, it will extinguiſh fire, and ſuffocate animals. Its producing the firſt of theſe effects is a ſign that it is collected in ſufficient quantity to cauſe the other. While candles continue to burn, we need not be afraid that this wild gaſs, as Helmont calls it, will be dangerous to life. It is on account of this ſpirit, that people are obliged to air wine-vaults, where wines are fermenting in the vintage ſeaſon, by ſetting open the windows, lighting fires, and letting in the wind.

In the progreſs of fermentation, the groſſer parts of the maſs begin to riſe to the top, and ſeparate there from the other liquor below, ſo as to collect into a ſpungy cruſt, which exactly covers the liquor underneath, and keeps in the more active parts thereof, in ſuch manner as to prevent their being exhaled and diſſipated before they have performed their effect. Now, it is curious to obſerve how great the agitation conſtantly is every where, even in the ſmalleſt part of the fluid matter, below this cruſt. A greater attrition can ſcarcely be conceived, than that which is here made with the utmoſt rapidity among all the particles. The cruſt being ſucceſſively broke, and raiſed up with a conſiderable noiſe, upon the returns of the exploſions, the exhalations eſcape, while the cruſt, preſently falling together, cloſes again, and prevents the active principles from exhaling otherwiſe. Thus, the formation and continuance of the cruſt is greatly aſſiſting in the due performance of fermentation.

As ſoon as all the groſs parts of the mixture are thus collected at the top, ſome leſs rarified particles of the lower part of the cruſt, being no longer ſuſtained by the light bubbles which cauſed them to aſcend, begin to ſink through the fluid, and are agitated upwards and downwards by bubbles in and about themſelves, by means of which they are again raiſed to the top, from whence, upon the breaking of the bubbles there, they again fall downward; and when they have done this ſeveral times, they at length remain quiet at the bottom. After this, new little maſſes do the ſame; and after ſome continuance thereof, it frequently

quently happens that all the upper cruſt, then grown heavier, or leſs rarified, on account of the air diſcharged, ſinks of a ſudden downward, but ſoon after rolls upward, almoſt entire, with ſuch a force as would ſeem incredible, if it were not ſeen. When the upper cruſt is thus gradually conſumed and fallen to the bottom, the fermentation ceaſes, though the ſame degree of heat be continued; and the liquor, then floating over the fæces which remain at the bottom, becomes tranſparent.

So long as the cruſt remains at top, it is called the flowers of the fermenting liquor, and is the moſt proper and immediate ferment. What falls to the bottom is called lees.

The time requiſite for the perfect completing of fermentation can hardly be determined, becauſe it is different in different liquors, and depends much on the ſeaſon of the year, and heat of the weather. The juice of the palm tree finiſhes its fermentation in a few hours in Africa; and this operation is likewiſe very ſoon ended in Aſia; but in the northern countries, it proceeds ſlower. In the heat of ſummer, it proceeds quick; but in winter more languidly. It is, however, eaſy to know when the fermentation is finiſhed, viz. when the whole ſeries of the phenomena above deſcribed, has ſucceſſively appeared, and is at length ſpontaneouſly gone off. Then the veſſel ſhould be immediately ſtopped down; and the liquor ſhould be kept for ſome time on its lees, a great part of which will be aſſumed and aſſimilated by the liquor, which will thereby become ſtronger and richer in ſpirit than it was before. If the veſſel is not ſtopped down, the ſpirit produced in the fermented liquor will ſoon exhale, and leave behind only a vapid uſeleſs fluid; but if the liquor is kept quiet in a cloſe veſſel, it will gradually become more pure and ſpirituous. The ſweeter and richer the juice is, the longer does the fermentation continue, and the ſtronger and more ſpirituous is the wine or other liquor.

The diſtinguiſhing marks of a vinous liquor are as follow: It has the faculty of inebriating, or of altering the actions of the ſpirits and animal functions, by refreſhing, animating, and exhilirating the drinker: after this, it raiſes the latent paſſions (*in vino veritas*;) and finally, it deſtroys the external and internal ſenſes and voluntary motions, and thus brings on palſy, ſleep, or at laſt death.

Fermentation alſo changes the relaxing, ſaponaceous, cooling, and generally purging virtues of vegetable juices, into ſuch as are ſtrengthening, coagulating, and healing. Thus, the freſh infuſion of malt, before fermentation; ſolution of ſugar or honey in water; the freſh expreſſed juices of ripe ſummer fruits, &c. when plentifully drank, prove flatulent, purgative, weakening, and cooling; but when properly fermented into beer, mead, or wine, they have quite contrary qualities, which they had not before. It is a very ſingular property of fermentation, that it produces from fermented liquor a ſpirit which is convertible into a liquid flame, and yet may be perfectly mixed with water.

The things, which promote fermentation, or tend to the better performance thereof, are free admiſſion and emiſſion of air, a warmth between fifty and ſeventy degrees, and the addition of a proper ferment.

It is found that when the ſweet juices are boiled down to a thick conſiſtence, they not only do not ferment in that ſtate, but are not eaſily brought to ferment, when diluted with as much water as they had loſt in the evaporation. Juices and decoctions in general, which have ſuffered much fire, however ſweet, are little diſpoſed to ferment.

One of the chief checks given to fermentation, is the fumes of burning ſulphur, received in a large quantity at ſeveral times, and ſhut up along with the air remaining on the top of the fermenting liquor. If the whole caſk be penetrated and filled with the fumes of burning ſulphur before the fermenting liquor is put in, and if the empty part on the top of the liquor be afterwards well filled with the ſame, and the veſſel cautiouſly bunged down, the fermentation will certainly be ſtopped: and if, after ſome time, it ſhould begin again, from the prevalency of its own cauſe, it may again be ſuppreſſed by the ſame fumes. The ſame end is alſo obtained by mixing with the fermenting matter a large quantity of any powerful acid, ſuch as acid ſpirits of vitriol, or nitre; though theſe at the ſame time prove hurtful to the fermenting liquor. Alkaline ſalts likewiſe, if added in a large quantity to fermenting liquors, immediately excite an increaſe of effervеſcence, which preſently ceaſing, all farther fermentation is ſtopped. But here too fermenting liquor is ſpoiled, ſo that it can ſcarcely be brought again to ferment, though it may to putrify. In the ſame manner, thoſe things which deſtroy acidity by drinking it up, hinder fermentation. Thus, chalk, teſtaceous and calcarious ſubſtances, iron, lead, tin, have this effect. Stopping up the containing veſſels ſo cloſe, that nothing can eſcape or enter, will ſtop the fermentation, provided the veſſel be ſo ſtrong as not to be burſt by the force of the confined liquor. This is manifeſt in new malt liquors, which, when included in ſtrong bottles, well corked, effervеſce violently upon receiving the air. The extracting of the elaſtic air ſtops fermentation: too great heat rather diſſipates and throws off the active principles of fermentation, than excites and promotes them; and, laſtly, too great a degree of cold likewiſe ſtops fermentation.

FERN, the name of one of the worſt of weeds, and one of the moſt difficult to deſtroy where it has a deep ſoil to root in. Mr. Mortimer ſays, he has ſeen its root eight or ten feet deep in ſome grounds; and adds, that the beſt way of killing it is by cutting it often while it is in graſs; that the moſt proper ſeaſons for this purpoſe are the ſpring, Midſummer, and Michaelmas: that is, when the circulation of the ſap is ſtrongeſt. Moſt of the roots being then cut aſunder, and thereby deprived of the channels through which nature intended to convey the ſap, will bleed to death, or, if it ſtagnates in them, they will ſoon rot. The fern itſelf, if cut when full of ſap, and left to rot upon the ground, will greatly improve the ſoil, and mellow it ſo as to prevent its binding: or, if it be burnt when ſo cut, it will yield a much greater quantity of ſalt, than any other vegetable. If it be ploughed up, plentiful dunging of the land, and ſprinkling it well with aſhes, have been found to kill this weed: but the moſt certain cure for it is urine. In ſeveral parts of the North, where they keep their fern under, and deſtroy a great deal of it by mowing it frequently when green, they alſo find that rolling of it is of great ſervice; and when they burn it, the poor people make the aſhes of it up into balls, with a little water, dry them in the ſun, and uſe them in waſhing their linen, for which they think them nearly as good as ſoap. Often treading down theſe plants, and feeding Scotch ſheep on them, is ſaid to be almoſt an infallible way of killing the fern.

Trees

Trees planted among fern will thrive very much, though it be on a hot gravel; the fern ſhading their roots, and keeping them moiſt and cool.

FERTILE, fruitful, abundant, plenteous.

FERTILITY, fecundity, abundance, fruitfulneſs.

FESCUE, the name of a genus of graſs, of which there are ſeveral ſpecies; as the flote-feſcue, the ſheep's feſcue, &c. *See the articles* FLOTE-FESCUE, SHEEP'S FESCUE, &c.

FESTING-PENNY, earneſt given to ſervants when hired.

FETLOCK, the tuft of hair that grows behind the paſtern-joint of many horſes; thoſe of low ſize have ſcarce any ſuch tuft.

FETTERS, chains for the feet.

FEVER, a diſeaſe that frequently attacks ſeveral ſorts of cattle, particularly horſes.

The ſymptoms which denote the horſe to be afflicted with a fever, are great reſtleſſneſs, the creature ranging from one end of the rack to the other; his flanks beat; his eyes are red and inflamed; his tongue parched and dry; his breath hot, and of a ſtrong ſmell; he loſes his appetite, and nibbles his hay, but without chewing it, and is frequently ſmelling to the ground; the whole body is hotter than ordinary (though not parched, as in ſome inflammatory diſorders) he dungs often, little at a time, uſually hard, and in ſmall bits; he ſometimes ſtales with difficulty, and his urine is high coloured; he ſeems to thirſt, but drinks little at a time and often; his pulſe beats full and hard, to fifty ſtrokes and upwards in a minute.

The firſt intention of cure is bleeding, to the quantity of two or three quarts, if the horſe is ſtrong and in good condition; then give him a pint of the following drink four times a day; or an ounce of nitre mixed up into a ball with honey, may be given thrice a day, inſtead of the drink, and waſhed down with three or four horns of any ſmall liquor.

Take of baum, ſage, and chamomile flowers, each a handful; liquorice root ſliced, half an ounce; ſal prunel, or nitre, three ounces; infuſe the whole in two quarts of boiling water, and when cold ſtrain it off; then ſqueeze into it the juice of two or three lemons, ſweeten it with honey.

As the chief ingredient to be depended upon in the drink is the nitre, it may, perhaps, be as well given in water alone; but as a horſe's ſtomach is ſoon palled, and he requires palatable medicines, the other ingredients may in that reſpect have their uſe. Soleyſel for this purpoſe adviſes two ounces of ſalt of tartar, and one of ſal armoniac to be diſſolved in two quarts of water, and mixed with a pail of common water, adding a handful of bran or barley-flower to qualify the unpleaſant taſte: this may be given every day, and is an uſeful medicine.

The following alſo may be given for this purpoſe:

Take Ruſſia pearl aſhes one ounce, diſtilled vinegar one pint, ſpring water two pints, honey four ounces; give a pint three or four times a day.

This neutral mixture, and the nitre drink above, may be taken alternately; they are both efficacious remedies, and in ſome caſes may properly enough be joined with the camphor drink.

His diet ſhould be ſcalded bran, given in ſmall quantities; which, if he refuſes, let him have dry bran ſprinkled with water: put a handful of picked hay into the rack, which a horſe will often eat, when he will touch nothing elſe: his water need not be much warmed, but ſhould be given often, and in ſmall quantities: his cloathing ſhould be moderate, too much heat and weight on a horſe being improper in a fever; which ſcarce ever goes off in critical ſweats (as thoſe in the human body terminate) but by ſtrong perſpiration.

If, in a day or two he begins to eat his bran, and pick a little hay, this method with good nurſing will anſwer; but if he refuſes to feed, more blood ſhould be taken away, and the drinks continued: to which may be added two or three drams of ſaffron, avoiding at this time all hotter medicines: the following clyſter ſhould be given, which may be repeated every day, eſpecially if his dung is knotty and dry.

Take two handfuls of marſhmallows, aud one of chamomile flowers; fennel ſeed an ounce; boil in three quarts of water to two, ſtrain off, and add four onnces of treacle, and a pint of linſeed oil, or any common oil.

Two quarts of water-gruel, fath broth, or pot-liquor, with the treacle and oil, will anſwer this purpoſe; to which may be added a handful of ſalt. Theſe ſort of clyſters are properer than thoſe with purging ingredients.

The following opening drink is very effectual in theſe fevers, and may be given every other day, when the clyſters ſhould be omitted; but the nitre-balls or drink may be continued, except on thoſe days theſe are taken.

Take of cream of tartar and Glauber's ſalts, each four ounces; diſſolve in barley-water, or any other liquor: an ounce or two of lenitive electuary may be added, or a dram or two of powder of jallap, to quicken the operation in ſome horſes.

Four ounces of Glauber ſalts or cream of tartar, with the ſame quantity of lenitive electuary, may be given for the ſame purpoſe, if the former ſhould not open the body ſufficiently.

In four or five days the horſe generally begins to pick his hay, and has a ſeeming reliſh to food: though his flanks will heave pretty much for a fortnight; yet the temper of his body, and return of appetite, ſhew that nothing more is requiſite to complete his recovery, than walking him abroad in the air, and allowing plenty of clean littter to reſt him in the ſtable.

This method of treating a fever is ſimple, according to the laws of nature; and is confirmed by long experience to be far preferable to the hot method.

The intention here is to leſſen the quantity of blood, promote the ſecretions of urine and perſpiration, and cool and dilute the fluids in general.

How far vinous cordials, ſtrong beer drinks loaded with fiery powders, and ſuch methods are likely to anſwer theſe purpoſes, is ſubmitted to the judicious obſerver; as alſo whether adopting the cool one in its ſtead is not as real an improvement in farriery as phyſic.

There is another ſort of fever that horſes are ſubject to, of a more complicated and irregular nature than the former, which, if not properly treated, often proves fatal.

The ſigns are a ſlow fever with languiſhing, and great depreſſions;

depreſſions; the horſe is ſometimes inwardly hot, and outwardly cold; at other times hot all over, but not to any extreme; his eyes look moiſt and languid; he has a continual moiſture in his mouth, which is the reaſon he ſeldom cares to drink, and when he does, it is but a little at a time. He feeds but little, and leaves off as ſoon as he has eat a mouthful or two; he moves his jaws in a feeble looſe manner, with an unpleaſant grating of his teeth; his body is commonly open; his dung ſoft and moiſt, but ſeldom greaſy; his ſtaling is often irregular, ſometimes little, at other times profuſe, ſeldom high-coloured, but rather pale, with little or no ſediment.

When a horſe's appetite declines daily, till he refuſes all meat, it is a bad ſign. When the fever doth not diminiſh, or keep at a ſtand, but increaſes, the caſe is then dangerous. But when it ſenſibly abates, and his mouth grows drier, the grating of his teeth ceaſes, his appetite mends, and he takes to lay down (which perhaps he has not done for a fortnight) theſe are promiſing ſigns. A horſe in theſe fevers always runs at the noſe, but not the kindly white diſcharge, as in the breaking of a cold, but of a reddiſh or greeniſh duſky colour, and of a conſiſtence like glue, and ſticks like turpentine to the hair on the inſide of his noſtrils. If this turns to a gleet of clear thin water, the horſe's hide keeps open, and he mends in his appetite; theſe are certain ſigns of recovery.

The various and irregular ſymptoms that attend this ſlow fever, require great ſkill to direct the cure, and more knowledge of the ſymptoms of horſes diſeaſes, than the generality of gentlemen are acquainted with. The experienced farrier ſhould therefore be conſulted and attended to, in regard to the ſymptoms; but very ſeldom as to the application of the remedy, which is generally above their comprehenſion; though it may be readily ſelected, by duly attending to the obſervations here inculcated.

Firſt then, a moderate quantity of blood, not exceeding three pints, may be taken away, and repeated in proportion to his ſtrength, fullneſs, inward ſoreneſs, cough, or any tendency to inflammation. After this, the fever drink may be given, with the addition of an ounce of ſnake-root, and three drams of ſaffron and camphor, diſſolved firſt in a little ſpirit of wine; the quantity of the nitre may be leſſened, and theſe increaſed, as the ſymptoms indicate.

The diet ſhould be regular; no oats given, but ſcalded, or raw bran ſprinkled; the beſt flavoured hay ſhould be given by handfuls, and often by hand, as the horſe ſometimes cannot lift up his head to the rack.

As drinking is ſo abſolutely neceſſary to dilute the blood, if the horſe refuſes to drink freely of warm water or gruel, he muſt be indulged with having the chill only taken off, by ſtanding in the ſtable; nor will any inconvenience enſue, but oftener an advantage; for the nauſeous warmth of water, forced on horſes for a time, pall their ſtomachs, and takes away their appetites, which the cold water generally reſtores.

Should the fever after this treatment increaſe, the horſe feed little, ſtale often, his urine being thin and pale, and his dung ſometimes looſe, and at other times hard, ſhould the moiſture in his mouth continue, his ſkin being ſometimes dry, and at others moiſt, with his coat looking ſtaring, and ſurfeited; upon theſe irregular ſymptoms, which denote great danger, give the following balls, or drink; for in theſe caſes there is no time to be loſt.

Take of contrayerva-root, myrrh, and ſnake-root powdered, each two drams, ſaffron one dram, mithridate or Venice treacle half an ounce, make into a ball with honey, which ſhould be given twice or thrice a day, with two or three horns of an infuſion of ſnake-root, ſweetened with honey; to a pint and a half of which may be added, half a pint of treacle-water, or vinegar, which latter is a medicine of excellent uſe, in all kinds of inflammatory and putrid diſorders, either external or internal.

Should theſe balls not prove ſucceſsful, add to each a dram of camphor, and where it can be afforded, to a horſe of value, the ſame quantity of caſtor. Or the following drink may be ſubſtituted in their ſtead for ſome days:

Take of contrayerva and ſnake-root, of each two ounces, liquorice-root ſliced one ounce, ſaffron two drams; infuſe in two quarts of boiling water cloſe covered for two hours, ſtrain off, and add half a pint of diſtilled vinegar, four ounces of ſpirit of wine, wherein half an ounce of camphor is diſſolved, and two ounces of mithridate or Venice treacle; give a pint of this drink every four, ſix, or eight hours.

A more ſimple drink, and perhaps full as efficacious may be thus prepared:

Take camphor one dram diſſolved in rectified ſpirit of wine one ounce, then gradually pour on a pint of diſtilled vinegar warmed, and give for two doſes. The quantity of camphor may be increaſed.

Should the horſe be coſtive, recourſe muſt be had to clyſters, or the opening drink: ſhould he purge, take care not to ſuppreſs it, if moderate; but if, by continuance, the horſe grows feeble, add diaſcordium to his drinks, inſtead of the mithridate; if it increaſes give more potent remedies.

Let it be remembered, that camphor is a very powerful and effectual medicine, in theſe kinds of putrid fevers; being both active and attenuating, and particularly calculated to promote ſecretions of urine and perſpiration. It has been long celebrated in malignant fevers, as it gives motion to ſtagnant humours, in the moſt diſtant parts, and promotes their expulſion by the common outlets; nitre may be advantageouſly joined with it in many caſes. Theſe are the medicines that are chiefly to be depended on in putrid and epidemic fevers, where the circulation is ſlow and languid, the blood and juices tending to coagulate, putrify, and run into grumes.

A horſe ſhould drink plentifully to promote the operation of theſe medicines; but inſtead of them, to a horſe of ſmall value, give an ounce of diapente, and half an ounce of mithridate, and one dram of camphor, with a ſtrong infuſion of rue, ſcordium, and ſnake-root, in the manner as above directed.

Regard ſhould alſo be had to his ſtaling; which, if in too great quantities, ſo as manifeſtly to depreſs his ſpirits, ſhould be controuled by proper reſtringents, or by preparing his drinks with lime-water. If, on the contrary, it happens that he is too remiſs this way, and ſtales ſo little as to occaſion a fullneſs, and ſwelling of his body and legs, recourſe may be had to the following drink.

Take

Take of sal-prunella, or nitre, one ounce; juniper-berries, and Venice turpentine, of each half an ounce; make into a ball with oil of amber.

Give him two or three of these balls, at proper intervals, with a decoction of marshmallows, sweetened with honey.

But if, notwithstanding the method we have laid down, a greenish or reddish gleet is discharged from his nostrils, with a frequent sneezing; if he continues to lose his flesh, and becomes hide-bound; if he altogether forsakes his meat, and daily grows weaker; if he swells about the joints and his eyes look fixed and dead; if the kernels under his jaw swell, and feel loose; if his tail is raised and quivers; if his breath smells strong, and a purging ensues, with a discharge of fætid, dark coloured matter, his case may then be looked on as desperate, and all future attempts to save him will be fruitless.

The signs of a horse's recovery are known by his hide's keeping open, and his skin feeling kindly; his ears and feet will be of a moderate warmth, his eyes brisk and lively; his nose grows clean and dry; his appetite mends; he lays down well, and both stales and dungs regularly.

Be careful not to over feed him on his recovery; let his diet be light, feeds small, and increased by degrees as he gets strength: for by overfeeding, horses have frequent relapses, or great surfeits, which are always difficult of cure.

This is the most successful method of treating these irregular, malignant fevers; where it is evident, by the various efforts nature makes to relieve herself, she wants assistance, and a spur to quicken her motions. For by the use of these warm medicines, a crisis, or termination of the disease is quickened and promoted, as appears by the alteration made both in the urine and skin; the former of which, by its thickness, shews signs of concoction, as it is called, or of a separation of the feverish matter from the blood; and the latter by its smoothness and glossiness proves that a regular and free perspiration is obtained: these two secretions are of such importance to the welfare of every animal, that the necessity of rectifying them, when disordered, is obvious from the consequences.

If this fever should be brought to intermit, or prove of the intermitting kind, immediately after the fit is over, give an ounce of jesuits-bark, and repeat it every six hours, till the horse has taken four or six ounces; should eruptions or swellings appear, they ought to be encouraged, for they are good symptoms at the decline of a fever, denote a termination of the distemper, and that no further medicines are wanted.

The true reasons perhaps why so many horses miscarry in fevers, are, that their masters, or doctors, will not wait with patience, and let nature have fair play: that they generally neglect bleeding sufficiently at first; and are constantly forcing down sugar-sops, or other food in a horn, as if a horse must be starved in a few days, if he did not eat: then they ply him twice or thrice a day with hot medicines and spirituous drinks, which (excepting a very few cases) must be extremely pernicious to a horse, whose diet is naturally simple, and whose stomach and blood, unaccustomed to such heating medicines, must be greatly injured, and without doubt are often inflamed by such treatment.

From the experience we lately had of the epidemic cold and fever among our horses, and from the observations of others in the years 1732 and 1734, it evidently appeared that the simplest method of treatment succeeded best. Thus it is proper to bleed largely at first, to the quantity of three quarts, if the horse is full and strong: and if it appears that his lungs are not relieved by it, but continue stuffed and loaded, the bleeding should be repeated; and a rowel may be put in his chest or belly.

Dilute the blood with plenty of water, or white drink; let his diet be warm bran mashes, and his hay sprinkled. Should the fever rise, which will be known by the symptoms above described, give him an ounce of nitre thrice a day in his water, or made up in a ball with honey. Let his body be kept cool and open, with the opening drink, given twice or thrice a week; or an ounce of salt of tartar may be given every day, dissolved in his water, for that purpose, omitting then the nitre. After a week's treatment in this manner, the cordial ball may be given once or twice a day, with an infusion of liquorice-root sweetened with honey; to which may be added, when the phlegm is tough, or cough dry and husky, a quarter of a pint of linseed, or sallad-oil, and the same quantity of oxymel squills.

As the kernels about the throat are greatly swelled in these cases, I need not mention the necessity of keeping the head and throat warmer than ordinary, to promote a freer perspiration, and forward the running at the nose, which in a horse answers the end of spitting, or expectoration in us: but the nose should never be syringed, as is sometimes done, to promote this discharge, which it often checks, and occasions bad swellings in the neighbouring parts and glands; for let it be remembered these are critical runnings of nature's own appointment, which by art may soon be frustrated. The following cooling purge is very proper to give at the decline of the distemper, and may be repeated three or four times.

Take two ounces of senna; anniseed and fennel bruised, each half an ounce; salt of tartar three drams; let them infuse two hours in a pint of boiling water; strain off, and dissolve in it three ounces of Glauber salt, and two of cream of tartar: give for a dose in the morning.

This purge generally works before night very gently; and in fevers, and all inflammatory disorders, is infinitely preferable to any other physic.

Before we close this account of fevers, it may be no improper hint to the curious, to take notice that a horse's pulse should more particularly be attended to than is customary, as a proper estimate may thereby be made both of the degree and violence of the fever present, by observing the rapidity of the blood's motion, and the force that the heart and arteries labour with, to propel it round. The nighest calculation that has been made of the quickness of the pulse in a healthy horse, is, that it beats about forty strokes in a minute; so that in proportion to the increase above this number, the fever is rising, and if farther increased to above fifty, the fever is very high.

How often the pulse beats in a minute may easily be discovered by measuring the time with a stop-watch, or minute sand-glass, while your hand is laid on the horse's near side, or your fingers on any artery; those which run upon each side of the neck are generally to be seen beating, as well as felt a little above the chest. *Bartlet's Farriery, page* 31.

FEWEL,

FEWEL, combuſtible matter; as fire, wood, coal, &c.

FIELD, a piece of ground encloſed, whether for tillage, or paſture.

FIELD *ſcabinus*, a perennial weed common among the corn. It is all over rough and hairy. The ſtalk is upright, and often a foot or a foot and a half high, ſpotted, and branching. The lower leaves are oval, and indented about the edges. Thoſe which grow on the ſtalk are divided, and of that ſort which botaniſts called pinnatified. The flowers are blue, and of the compound kind, conſiſting of a conſiderable number of ſmall flowers, each divided into four parts, and having one ſeed under them. The taſte of the plant is a diſagreeable bitter.

FIG, the name given by farriers to a ſort of wart on the fruſh, and ſometimes all over the body of a horſe. The figs that appear on the fruſh or ſole, diſcharge a malignant ſtinking humour, which is very difficult to cure.

FIG-WORT, *pile-wort*, or *leſſer centaury*, a perennial weed common in paſture-grounds. The roots conſiſt of oblong knobs. The leaves are heart-ſhaped, cornered, and placed on foot-ſtalks. The flowers in general reſemble thoſe of the crowsfoot, but differ ſomewhat from them in having the cup divided into three parts only, the petals being about eight in number, and narrower. This low plant runs very much by the roots, and choaks all others which are near it.

FILLER, or *thiller* horſe, that faſtened immediately to the cart, and which ſupports the ſhafts.

FILLY, a female or mare colt.

FIMBLE-*hemp*, early ripe hemp.

FINE-BENT, the name of a very excellent ſpecies of graſs found in great plenty on the beſt ſheep-paſtures. We have given a figure of this graſs on Plate XV. Fig. 4. *See the article* GRASS.

FIRE-BLAST, an accident to which hops are very liable. *See the article* HOPS.

FIRE-BOTE, a quantity of fuel.

FIRING, an operation often performed on different parts of a horſe. It is done in the following manner: when the firing-iron is red hot, the farrier applies the thinneſt part to the horſe's ſkin, in one or more places, according to the nature of the diſeaſe.

Firing, or cauterizing, is often neceſſary after ſtrains and other accidents, which may occaſion a long continued weakneſs, or where there is a fullneſs, and the part is grown hard and callous, eſpecially about the joints, ſinews, and nervous parts, thoſe parts being compoſed of an infinite number of fibres and nervous threads, which lie ſo cloſe together, that nothing but what is of the moſt powerful nature is ſufficient to relieve them when obſtructed. This is performed in the moſt effectual manner, by burning the outſide, and giving vent to the incloſed matter to diſcharge itſelf; and ſometimes proves beneficial, when all other helps have been found ineffectual.

In firing about the ſinews and nervous parts, great care is to be taken not to go too deep at firſt, but by gentle repeated razes or lines, till they come to a pale red colour; for if the fire once touches the ſinew, it will make the horſe go lame as long as he lives: the ſame ought to be drawn pretty cloſe together on each ſide the joints or ſinews, following the courſe of the hair, without making of croſs lines, which are of no uſe in theſe parts, and are only apt to diſfigure the horſe afterward.

When the more fleſhy parts, or an obſtinate humour, that cannot be brought to ſuppuration, requires firing, the ſkin ought to be pierced deeper, in order to draw away a ſufficient quantity of matter from the part; the ſame ought to be performed upwards, to prevent any ulcerous diſpoſition attending it: and in ſuch caſes little ſoft doſils of tow, dipped in warm baſilicon, and ſpirit of wine, may be thruſt gently up into the orifices.

The firing inſtrument, or knife, ought to be ſomewhat rounded on the edge, and gradually thicker to the back, ſufficient to keep the heat of the fire for ſome time; the ſame ſhould be rubbed clean, that no dirt or aſhes may ſtick to it, and not uſed until the flaming redneſs is in part gone off. All the ſeared parts ought immediately to be bathed with ſpirits of wine, and where nothing elſe is requiſite to complete the cure, the place is only to be anointed with oil and bees-wax melted together. *Gibſon's Farriery, vol.* I. *page* 251.

FIRING-IRON, a piece of iron about a foot long, one end of which is made flat, and forged like a knife, the back of it being half an inch thick, and the edge about the eighth of an inch.

FIR, a timber tree very common on mountainous and barren places, eſpecially in the colder climates. It differs from the pine in having ſingle leaves, which are, for the moſt part, produced on every ſide of the branches; whereas the pine has two or more leaves produced out of the ſheath or cover.

Fir trees are raiſed from ſeeds taken out of their polyſpermous cones. The way to get out the ſeeds is, either by expoſing the cones to a gentle fire, or by ſoaking them all night in water, which will cauſe their ſquamous cells to open, and readily emit their ſeeds. The former method is the beſt, provided they are not expoſed to too great heat. But this ought not to be done until you are ready to ſow them, which is beſt performed in the beginning of March.

Theſe plants ſhould be all raiſed in a nurſery, where they may be protected from the birds, otherwiſe they will be in danger of being deſtroyed, when they firſt come up: for as they bring up the huſk of the ſeed on the top of the plant, the birds in picking off the huſk will break off the plant, whereby a whole bed may be loſt in a few hours, if they are not carefully guarded from them.

The beſt time of ſowing theſe ſeeds is about the latter end of March, or the beginning of April, on a bed of light earth, covering the ſeeds about half an inch deep with the ſame ſort of earth. In this bed the plants ſhould remain until the following ſpring, when there ſhould be a number of beds prepared in the nurſery to receive theſe ſeedling plants; and the beginning of April they ſhould be tranſplanted into the beds, at the diſtance of ſix inches row from row, and at three inches aſunder in the rows. If the ſeaſon ſhould prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; and the beds ſhould be covered with mats, to ſcreen the plants from the ſun, and drying winds, until they have taken good root; after which time they will require no farther care, but to keep them clear from weeds. In theſe beds the plants may remain two years; at the end of which they ſhould be tranſplanted into an open ſpot of ground; for their roots will in that time meet quite over the beds.

The diſtance which theſe plants ſhould be planted in this nurſery, ſhould be four feet row from row, and two feet aſunder in the rows.

When the plants are planted, if the ſeaſon ſhould prove dry, they ſhould be watered, to ſettle the earth to their roots; and if this is repeated three or four times, if the ſeaſon ſhould continue dry, it will greatly promote their taking new root, and ſecure them from the injuries of the drying winds. In this nurſery the plants may remain two or three years, according to the growth they ſhall have made; and, during this time, the ground between the plants ſhould be conſtantly kept clean from weeds, and dug between the rows every ſpring; in doing of which, care muſt be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nurſery: and, when they are tranſplanted into the places where they are to remain, the neceſſary care to be taken is, in taking them up, not to injure or cut off their roots, and let them be as little time out of the ground as poſſible; and, when they are out, to guard their roots from the drying winds. The ſureſt time for removing of theſe trees is about the beginning of April; though they may, and often are removed with ſucceſs at Michaelmas, yet the ſpring is the more ſure ſeaſon, eſpecially in moiſt land.

Moſt of the kinds of firs may be removed at the height of ſix or ſeven feet; but thoſe of two feet high are much better, and will in a few years get the better of thoſe taller trees. *Miller's Gard. Dict.*

FISH-PONDS, reſervoirs of waters, applied to the breeding or feeding of fiſh.

Fiſh-ponds are no ſmall improvement of watery and boggy lands, many of which are fit for no other uſe. In making of a pond, its head ſhould be at the loweſt part of the ground, that the trench of the flood-gate, or ſluice, having a good fall, may not be too long in emptying. The beſt method of making the head ſecure, is to drive in two or three rows of ſtakes above ſix feet long, at about four feet diſtance from each other, the whole length of the pond head, whereof the firſt row ſhould be rammed at leaſt about four feet deep. If the bottom is falſe, the foundation may be laid with quick-lime, which ſlacking, will make it as hard as a ſtone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and ſtakes; and when theſe are well covered, drive in others, as they ſee occaſion, ramming in the earth as before, till the pond-head be of the height deſigned.

The dam ſhould be made ſloping on each ſide, leaving a waſte to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepeſt part need not exceed ſix feet, riſing gradually in ſhoals towards the ſides, for the fiſh to ſun themſelves, and lay their ſpawn. Gravelly and ſandy bottoms, eſpecially the latter, are beſt for breeding; and a rich ſoil with a white fat water, as the waſhing of hills, commons, ſtreets, ſinks, &c. is beſt for fattening all ſorts of fiſh. For ſtoring a pond, carp is to be preferred for its goodneſs, quick growth, and great increaſe, as breeding five or ſix times a year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds that have marl or clay bottoms, with plenty of weeds and graſs, whereon they feed in hot months.

Your pond ſhould be drained every three or four years, and your fiſh ſorted. If it is a breeding one, the ſmaller ones are to be taken out to ſtore other ponds with, leaving a good ſtock of females, at leaſt eight or nine years old, as they never breed before that age. In feedings ponds it is beſt to keep them pretty near of a ſize. *Mortimer's Huſbandry, vol* I. *page* 290.

FISTULA, a deep, narrow, and callous ulcer, generally ariſing from abſceſſes. *See* ULCER.

FISTULAR, FISTULOUS, an epithet applied by farriers to wounds and ulcers, which degenerate into fiſtulas.

Fiſtular, or *fiſtulous*, is alſo an epithet applied by botaniſts to leaves and flowers which are tubular, or that reſemble a hollow pipe.

FLAGS, the turf, or ſurface of the ground, which they pare off for burning. *See* BURN-BAKING.

FLAIL, a well known implement of huſbandry, uſed in threſhing all ſorts of corn. *See the article* THRESHING.

FLAX, the name of a plant cultivated both for the ſake of its ſtalk and ſeed, the former being uſed in making linen, and the latter for oil.

The ſtem of this plant, which is round and hollow, grows to the height of about two feet, and then divides into ſeveral branches: theſe are terminated by blue flowers, conſiſting of five petals, and are ſucceeded by capſules divided within into ten cells, in each of which is encloſed a bright, ſlippery, elongated ſeed. Its leaves are long, narrow, ſharp-pointed, and placed alternately along the ſtem and branches.

The ſoil for flax ſhould be a ſtiff loam, rendered fine by tilth, and ſituated in a valley bordering upon water; or ſuch a ſoil as is thrown up by rivers. If there be water at a ſmall depth below the ſurface of the ground, it is thought ſtill better, as is the caſe in Zealand, which is remarkable for the fineneſs of its flax, and where the ſoil is deep and ſtiff, with water almoſt every where, at the depth of a foot and a half, or too feet underneath it. It is ſaid to be owing to the want of this advantage, that the other provinces of Holland do not ſucceed equally well in the culture of this uſeful plant; not but that fine flax is alſo raiſed on high lands, if they have been well tilled and manured, and if the ſeaſons are not very dry.

It is juſtly remarked in the letters which the Dublin Society have publiſhed on the culture of flax, that moiſt ſtiff ſoils yield much larger quantities of flax, and far better ſeed, than can be obtained from light lands: nay, that the ſeed procured from the former may, with proper care, be rendered full as good as any that is imported from Riga or Zealand: but, as M. Du Hamel rightly obſerves, ſtrong land can hardly yield ſuch fine flax as that which grows on lighter ground.

In the ſouthern countries, the huſbandmen who raiſe flax, ſow part of their ſeed in September and October; ſo that the plants which ſpring from thence, remain of courſe in the ground all the winter; and this is a judicious practice in thoſe places, becauſe plants which have not covered the earth well before the ſummer heats come on, are apt to be parched by the heat and drougth which uſually prevail in that ſeaſon. They ſow linſeed again in the ſpring; but the latter do not yield ſo large a crop: the flax, however, which it produces is more eſteemed, becauſe it is finer than that ſown in autumn. M. Du Hamel ſeems, indeed to think, that the autumnal ſowing yields the beſt ſeed; but however that be, in places where the winter is apt to be ſevere, and where the flax, which is but a tender plant, would in courſe be in danger of being deſtroyed during that ſeaſon, almoſt all the flax is ſown about the

end

end of March, or in the beginning of April. This ſpring flax is what we ſhall principally conſider in this article.

It may be laid down as a general rule, that the land which is intended for flax ſhould be brought to exceeding fine tilth by repeated ploughings, and that it ſhould be enriched by a manure ſuited to the quality of the ſoil. Thus, when a paſture is broken up in order to its being ſowed with flax, it muſt be well ploughed during eighteen months, or two years, before it will be fit for producing a crop of flax. To defray the expence of this culture, ſome other crops may be got off the land in the mean time, eſpecially of ſuch plants as do not occupy it long, and particularly of thoſe which are remarkably benefited by frequent ſtirring of the earth whilſt they grow; ſuch as beans, peaſe, turnips, &c. becauſe theſe repeated ſtirrings render the mould fine and looſe, and help to kill the weeds, which would otherwiſe do great damage to the flax. The Memoirs publiſhed by the Society of Brittany informs us, that the Livonians, when they clear woodland, burn the wood upon it, then plough it, and in this ſtate prefer it to any other kind of ſoil for flax.

If the land which is intended for flax be ſtiff, great care ſhould be taken not to till it when it is wet, for fear of kneading it.

If the ground on which flax is to be raiſed has been long in tillage, it ſhould be ploughed deep before winter, and laid up in very high ridges, in order that the winter's froſts may the more effectually moulder or looſen it.

In the month of February, if the land be not too wet, ſome very rotten dung ſhould be laid in the furrows, and immediately covered over. In March, for ſouthern countries, or in the beginning of April, where the climate is colder, another ploughing ſhould be given to lay the land ſmooth, the clods ſhould be broken by hand, or with the ſpiky-roller, and the ſeed ſhould then be ſown and harrowed in with a light or buſh-harrow, ſo as not to bury it above an inch deep. If the ſoil be moiſt and cold a little pigeon's dung may be ſown with the ſeed, for it agrees admirably well with the flax: but this muſt not be done if the ground is very light and too dry. It will alſo be right to lay wet land out in beds thirty or forty feet wide, ſeparated by deep trenches, to drain off the water, and convey it into the ſurrounding ditches.

Moſt of our linſeed is brought from the North, namely from Riga and Zealand: but we may ourſelves raiſe it very good, by conforming to the directions here given.

Linſeed is reckoned good when it is large, oily, heavy, and of a bright brown colour. To know whether it be oily, a few grains of it are thrown into a red-hot fire-ſhovel, and they in that caſe crackle almoſt inſtantly and blaze briſkly. If it is ſufficiently heavy, it will ſink to the bottom of water; and to judge whether it be new, a number of ſeeds exactly counted ſhould be ſown on the end of a hot-bed, and notice taken whether they all grow.

When the goodneſs of the ſeed is known, more or leſs of it is to be ſown according as the huſbandman intends either to raiſe a quantity of linſeed for ſowing, or to have very fine and ſoft flax. In this laſt caſe, the ſeed ſhould be ſown pretty thick, in order that the plants may riſe the cloſer together, and by that means grow ſlender and tall, which adds much to the fineneſs of the fibres of the flax. If the linſeed is ſown with an intention to let the flax remain for ſeed, a much leſs quantity of it ſhould be uſed, that ſo the plants may come up thin, and thereby have room to grow to their full vigour and extent. As ſtrong ſoils ſhould be choſen for this purpoſe, it may perhaps be moſt adviſable to follow the example of the judicious M. de Chateauvieux, in ſowing it in drills, and horſe-hoeing the intermediate ſpaces. He obſerved in his experiments, that the plants of flax thus raiſed yielded great plenty of excellent ſeed.

Some ſow, with their linſeed, either annual or perennial graſs-ſeeds, when they intend to lay the land down for paſture after the flax is taken off. The plants grow but weakly under the flax, which, however, they do not hurt; but as ſoon as the flax has been pulled, they increaſe apace, to the great benefit of their owner.

Flax is ſometimes damaged by inſects when it is about three or four inches high. It is ſaid that they may be deſtroyed by a ſlight ſtrewing of ſoot, aſhes, &c. At all events, it is certain that this dreſſing will give vigour to the flax, though it ſhould not kill the inſects.

If any weeds appear among the flax, as is almoſt always the caſe, they muſt be thoroughly rooted out; and that the flax may be as little damaged as poſſible in the doing of this, the weeders ſhould work bare-footed: they may indeed ſit down upon the flax, for ſitting upon it is found not to hurt it; but it would be greatly injured, if not killed, by being trod upon with the heels of ſhoes.

The fineſt flax is moſt liable to be laid, particularly in countries ſubject to ſtorms. To guard againſt this accident, ſome people run acroſs their flax field ſlender poles fixed to ſtakes: but a better method, and which is practiſed by the ingenious gentleman who directs the cambrick manufactory at Winchelſea, is, to run ſmall ropes acroſs the field, both lengthwiſe and breadthwiſe; for theſe, being faſtened where they interſect one another, and ſupported by ſtakes at due diſtances, form a kind of netting, which is proof againſt almoſt every accident that can happen from tempeſtuous weather.

Opinions are divided in regard to the degree of ripeneſs at which it is beſt to pull flax. Some think it ſhould be pulled whilſt it is green, in order that its fibres may be the ſofter and finer. Others, with the ſame view, pull it up before its ſeeds are quite formed; and others again think, that it ſhould not be pulled till ſome of the capſules, which contain the ſeeds, have begun to open, being of opinion, that the fibres of green flax are too tender, and that they fall into tow. On the other hand, it is certain, that the fibres of flax which has ſtood till it is very ripe, are always ſtiff and harſh, that they are not eaſily ſeparated from the reed, and that they do not bleach well. Here, therefore, as in moſt other caſes, both extremes ſhould be avoided; and it conſequently ſeems moſt reaſonable to think, that the propereſt time for pulling flax, is when its ſtalks begin to turn yellow, when its leaves begin to fall, and when its ſeeds begin to be brown.

As ſoon as the flax is thought to have attained a due maturity, it is pulled generally by handfuls: but as it is ſeldom all of an equal degree of ripeneſs, or of an equal degree of ſtrength, it would certainly be adviſable to pull firſt the ripeſt and ſtrongeſt plants, and then the weaker and leſs ripe; for by this means they would at once be ſeparated, which is of eſſential importance in the watering, becauſe the weak and green flax requires much leſs ſteeping than the ſtronger and more ripe. All weeds, and the earth which adheres to the roots of the plants, ſhould be

carefully taken away, and then the handfuls of flax ſhould be laid regularly on the ground.

The author of the judicious letters concerning flax, in the Dublin Society's Weekly Obſervations, ſeems to direct a too great degree of ripeneſs of the flax when it is pulled, and aſſigns as a reaſon, that it does not otherwiſe ſtand the force of the mill for ſcutching it. But as it has been found by experience, that the force of that mill is too great, and as a better method of performing this operation, in which the force can be ſuited to the ſtrength of the flax, will ſoon be publiſhed, this great degeee of ripeneſs will become the leſs neceſſary.

As the flax is pulled, it is laid together by handfuls, with the ſeed ends turned to the ſouth. Theſe handfuls ſhould neither lie quite in a line with each other, nor directly acroſs, but a little ſlanting upwards, ſo that the air may eaſily paſs through them. Some, inſtead of this method, tie the handfuls of flax looſely at the top, then ſpread out their roots, and thus ſet ſeveral of them together upright upon their roots. In either of theſe ways, the flax is generally left twelve or fourteen days in the field to dry it. This drying is certainly not neceſſary for the rippling, becauſe the ripple will ſeparate the capſules from the flax as effectually before it has been dried, as it will afterwards; and if it be done with a view to ripen the ſeed, it ſhould be conſidered, that the flax will be more hurt by the longer time of ſteeping, which will become neceſſary in conſequence of this drying, than the ſeed can be benefited; becauſe the more the membrane which connects the fibres to the reed is dried, the greater muſt be the degree of putrefaction neceſſary to looſen and deſtroy the coheſion of this connecting membrane: the finer parts of the flax itſelf muſt neceſſarily be deſtroyed by this degree of putrefaction; and if the putrefaction does not ariſe to ſuch a degree as to deſtroy the coheſion of this membrane, the fibres of the flax will adhere ſo ſtrongly to the reed, that the force neceſſary in ſcutching will prove equally detrimental to the flax. The practice in ſome parts of Brittany, as we are informed by the Memoirs of the Society of that province, ſeems therefore much more rational; and this is, to ripple the flax after it has lain in the air two or three days: but even one day will be ſufficient if the weather is dry.

If any flax is raiſed on purpoſe for ſeed, or if, through the dryneſs of the ſeaſon, or the badneſs of the ſeed that was ſown, the flax is come up very thin, ſo as manifeſtly to ſhew, that the ſeed which it may produce will be more valuable than the reſt of the crop; in either of theſe caſes, the flax ſhould be let ſtand till its ſeed is perfectly ripe; thus ſacrificing the flax itſelf to the then greater advantage of having good ſeed.

In order to ripple the flax, which is the next operation, a large cloth ſhould be ſpread on a convenient ſpot of ground, with the ripple placed in the middle of it. The manner of performing this work is ſo well known, that there can be no need to deſcribe it here. Its purpoſe is to obtain the linſeed, which is always of conſiderable value, even though the flax has been pulled before its perfect maturity.

After the flax has been rippled, the ſeeds thereby obtained ſhould be ſpread in the ſun, to dry. Thoſe which ſeparate from the pods of their own accord are the fulleſt and ripeſt, and ſhould therefore be ſet apart for ſowing, in caſe the precaution of raiſing ſome flax purpoſely for ſeed has not been attended to. The pods, or capſules, are then broken, either by treading or by threſhing, in order to get out the remaining ſeeds, the whole of which, as well as the former, ſhould be carefully ſifted, winnowed, and cleaned. When the ſeed is laid up, it muſt be frequently ſtirred, or ventilated, to prevent its heating. Even this ſecond ſeed affords a conſiderable profit, by the oil which it yields, and alſo by being uſed, when broken, for fattening of cattle. The cakes of linſeed, after the oil has been preſſed out of them, are likewiſe found to be uſeful for this laſt purpoſe, though they are thought to render the fat of cattle yellow; for which reaſon it is adviſed not to give them till within a few weeks before the beaſts are to be killed. Their utility as a manure has been already mentioned.

As ſoon as the flax has been rippled, it ſhould be carried with all convenient ſpeed to the watering place. If care has not been taken before to ſeparate the different kinds of flax, that ſeparation muſt now be made: becauſe otherwiſe, ſome of the flax will be rotted in the water, before the reſt will be ſufficiently ſteeped.

The choice of the water for ſteeping it in is thus very properly pointed out in the directions for raiſing flax, publiſhed by order of the commiſſioners and Truſtees for Fiſheries, Manufactures, and Improvements, in Scotland.

"All flax ought to be watered in canals, which ſhould be dug in clay ground if poſſible, becauſe that ſoil beſt retains the water: but if a firm retentive ſoil cannot be got, the bottom and ſides of the canal, or rather both the bottom and ſides, may be lined with clay; or, inſtead of lining the ſides with clay, which might fall down, a ditch may be dug without the canal, and filled with clay, which will prevent both extraneous water from entering, and the water within from running off.

"A canal of forty feet long, ſix broad, and four deep, will generally water the produce of at leaſt an acre of flax.

It ſhould be filled with freſh ſoft water from a river or brook, if poſſible, two or three weeks before the flax is put in, and expoſed all that time to the heat of the ſun. The greater way the river or brook has run, the ſofter, and therefore the better, will the water be. Springs, or ſhort runs from hills, are too cold, unleſs the water is allowed to ſtand long in the canal. Water from coal or iron is very bad for flax. A little of the powder of galls thrown into a glaſs of the water, will immediately diſcover if it comes from minerals of that kind, by turning it into a dark colour, more or leſs tinged in proportion to the quantity of vitriol contained in it.

"The canal ought not to be under any ſhade, becauſe this, beſides keeping the ſun from ſoftening the water, might render ſome parts of the canal cooler than other parts, and thereby make it water the flax unequally.

"The flax raiſer ſhould obſerve, that, when the water has been brought to a proper degree of heat by the ſun, ſmall plants will riſe quickly in it, numbers of ſmall inſects and reptiles will generate there, and bubbles of air will riſe up to its ſurface. If no ſuch ſigns appear, he may conclude, that the water is not warm onough, or that it is otherwiſe unfit for flax."

Running water is not proper for ſteeping flax, becauſe it prevents that degree of putrefactive fermentation which is neceſſary to ſeparate the fibres from the reed; and beſides this, in ſuch ſtreams, the flax is apt to be carried away by ſudden floods, or to be filled with the mud and ſlime which thoſe floods bring with them: but to have a ſmall rill of water paſs through the ſteeping place is very adviſable,

adviſable, becauſe it will ſupply the loſs of that which is evaporated. Stagnant water, which is naturally of a bad colour, ſhould likewiſe be avoided, becauſe this communicates to the flax a colour which is not afterwards eaſily got rid of.

The flax, after it has been rippled and ſorted, as before mentioned, ſhould be tied very ſlack, with a band made of a few ſtalks, in bundles not larger than a man can eaſily graſp with both his hands, in order that the water may the more eaſily and more equally penetrate through them; and in this condition they ſhould be put into the canal, ſomewhat ſloping, or even half-ſtanding upon one end, which, ſay the Edinburgh directions, ſhould be the ſeed end, and conſequently the root end uppermoſt; becauſe, add they, (though I do not find it at all noticed by any other writers on the ſubject) when the ſeed ends are uppermoſt, there frequently breeds a great deal of vermin, deſtructive of the flax, and this, they aſſure us, is effectually prevented by putting the ſeed end downmoſt. However this may be, the flax, when put into the water, ſhould be covered with ſtraw, or fern, upon which a wicker hurdle and ſome ſtones may be laid, to keep it down, but without preſſing too hard againſt the bottom. It is a common opinion, that if the flax is not thus covered, the ſun will diſcolour it, even though it be quite covered with water.

More or leſs time is requiſite for the ſteeping of the flax, according to the nature of the water, the heat of the air, and the greater or leſs degree of woodineſs of the flax. It is ſteeped ſooner with a ſouth than a north wind: and that which has been pulled green is alſo much ſooner ſteeped than that which has been pulled when very ripe: conſequently it is not poſſible to fix any preciſe length of time during which it ſhould remain in the water. The way to know whether it has been ſteeped enough, is to draw a few ſtalks from out of the middle of the heap, and then try it: if the reed ſnaps ſhort, without bending, and if the bark parts eaſily from the reed, towards its point, the hemp has been ſufficiently ſteeped, and it muſt, in this caſe, be ſpeedily taken out of the water, for otherwiſe it will ſoon become too tender, and begin to rot.

In ſome countries, the flax is ſteeped but four days, at the end of which it is taken out of the water, and the little bundle, or handfuls, into which it was before made up, are laid regularly ſide by ſide, till they have formed a pretty thick bed, upon which are then put planks loaded with ſtones. The flax is left in this condition four or five days, or more, according to the heat of the air; and its lying thus in a heap anſwers the intent of farther ſteeping in water: but as a great degree of putrefaction may ariſe in this operation, ſo much judgment and care are neceſſary, that I cannot think it an adviſable method.

The memoirs of the Society, which the States of Brittany have inſtituted, upon a truly judicious plan, for the improvement of agriculture, arts, and commerce, inform us, in conſequence of an account which the duke of Choiſeuil, miniſter of ſtate in France for foreign affairs received from the French ambaſſador at the court of Ruſſia, to whom he had written on this ſubject, at the requeſt of the ſociety, that the Livonians uſe two ſorts of places for ſteeping their hemp and flax; that the moſt ſimple of theſe are only holes dug near the ſide of rivers, and that the flax, or hemp, watered in them (which is very like the method practiſed in France) generally ſells for from twenty-five to thirty per cent. leſs than that which has been ſteeped in the following manner.

When they would have flax or hemp of ſuperior quality, they chooſe a ſpot where there is a fall of clear water, and there make, one under another, five, and ſometimes ſix, baſons or reſervoirs, each of which is at leaſt one foot, and at moſt two feet deep. The water can either be let run from one baſon to another, or be ſtopped at pleaſure. The baſons are ſeparated by ſlight banks of clay; and in each bank is a little opening, which may be cloſed whenever it is thought proper. To prevent the ſtream from overflowing the firſt baſon, and afterwards ſucceſſively the others, it is itſelf turned a little aſide by a ſmall bank of clay, and this bank is broken down whenever the water is to be renewed in the baſons.

The Livonians put their hemp and flax firſt into the uppermoſt baſon only. At the end of two, three, or four days, they remove it into the ſecond baſon, from thence into the third, and ſo on, till they have brought the ſeveral bundles of theſe plants down into the loweſt. At each of theſe ſhiftings, the firſt baſon is filled with freſh flax, and the water is renewed in all the baſons. By this means, the ſteeping is not completed till the flax or hemp has paſſed through all the baſons, and has remained a proper time in the lowermoſt, which is the laſt. Neither the Engliſh nor the Dutch import any hemp from Riga, but what has been ſteeped in this laſt mentioned manner; whereas a great part of that which the French receive from thence, is ſuch as has been ſteeped in ſtagnant waters, in holes dug on the ſide of rivers.

When the flax is taken either out of the water in which it has been ſteeped, or from the heap above-mentioned, the bundles of it are ſpread out, like a fan, at the root end, and laid on dry new-mown meadow, that it may dry, bleach, and become ſupple. It is there turned from time to time, and as ſoon as it is quite dry it is carried off: for otherwiſe the moiſture of the dews and graſs will have nearly the ſame effects upon it, as if it had remained longer in the water. This is evinced by the practice of thoſe, who, in ſome places, inſtead of putting their flax into water, only ſpread it on a damp meadow where the graſs is ſomewhat long, leave it there all night, and in the morning, before the ſun has dried it, gather it up in large heaps, and remove it into the ſhade, in order to ſpread it out again on the graſs the next evening; and this is repeated till the flax is found to be ſufficiently watered. In other places, it is watered by hand during the day, and ſo let it remain conſtantly on the graſs. It is then let dry, and is afterwards houſed. But, as M. Du Hamel rightly obſerves, this method is ſo tedious and troubleſome, that, even if it ſhould, as ſome ſay it does, give a little additional whiteneſs to the flax; yet the advantage in that reſpect is ſo ſmall, as by no means to compenſate for the inconveniences of the practice, which he therefore thinks is not adviſable in any caſe, unleſs it be when the flax, after being taken out of the water, is found not to have been ſufficiently ſteeped.

The diſadvantage of laying the flax upon long graſs, after it has been ſteeped, in order to dry it, is very juſtly pointed out in the Directions for raiſing Flax, publiſhed by order of the commiſſioners and truſtees for fiſheries, manufactures, and improvements in Scotland, when they adviſe the huſbandman by no means to follow this method, becauſe the graſs, growing through the flax, frequently ſpots, or rots it. Theſe judicious gentlemen therefore recommend ſhort heath as the moſt preferable place for ſpreading flax upon, after it has been taken out

of the water; and this the rather, becauſe, when the flax is wet, it faſtens to the heath, and is thereby prevented from being blown away by the wind, whilſt at the ſame time the heath keeps it a little above the earth, and ſo expoſes it the more equally to the weather: but grounds expoſed to violent winds ſhould alſo be avoided.

"The flax, continue they, when taken out of water, muſt be ſpread very thin upon the ground; and as it is then very tender, it muſt be gently handled. The thinner it is ſpread, the better, as it is then moſt equally expoſed to the weather: but it ought never to be ſpread during a heavy ſhower, becauſe that would waſh and waſte too much the bark, which is then exceſſively tender; though it ſoon after becomes firm enough to bear the rains, which, with the open air and ſunſhine clean, ſoften, and purify it to the degree deſired, and fit it admirably for parting from the reed: in ſhort, after the flax has acquired a little firmneſs by being a few hours ſpread in dry weather, the more rain and ſunſhine it gets, the whiter and better it will be.

"The ſkilful huſbandman, who follows this method, ſpreads his firſt row of flax at the end of the field from whence the moſt violent wind commonly comes, placing the root-ends foremoſt: he makes the root-ends of every other row overlap the ſeed-ends of the former row three or four inches, and binds down the laſt row with a rope; by which means the wind does not eaſily get below the flax, to blow it away: and as the ſeed-ends are ſeldom ſo fully watered as the root-ends, this over-laying has an effect like giving the ſeed-ends more watering.

"The flax is judged to have been ſufficiently graſſed, when it is of a clearer colour than before, when its bark is bliſtered up, when that bark parts eaſily from the reed, and when the reed is become very brittle: but no written deſcription can poſſibly here convey a knowledge of this point, at all equal to that which is acquired by experience.

"The whole of the flax ſhould be ſufficiently graſſed before any of it is lifted; for if a part be liſted ſooner than the reſt, that which remains will be in great danger from the winds.

"A dry day ſhould be choſen for taking up the flax; and if there is no appearance of high wind, it ſhould be looſed from the heath or graſs, and left looſe for ſome hours, to make it thoroughly dry.

"As a great quantity of flax can ſcarcely be equally watered and graſſed, and as its different qualities will beſt appear at lifting it off the graſs, each different kind ſhould then be collected together, and kept by itſelf, that is to ſay, all of the ſame colour, length, and quality.

"The ſmaller the bundles are into which the flax is made up, the better they will be for drying, houſing, &c. and in making up theſe bundles, as in every other operation upon flax, it is of great conſequence that all the ſtems be laid together as they grew, that is to ſay, root-ends to root-ends, and ſeed-ends to ſeed ends.

The Livonians, ſay the before quoted Memoirs of the Society of Britany, cut off the roots of their hemp, but not of their flax, when it is taking out of the ſteeping baſons above deſcribed. They then tie the flax or hemp up in bundles about as thick as the lower part of a man's thigh. Theſe bundles are placed upright, and ſupported by a ſtake, around which a few of the tops of their ſtalks are twiſted, the better to ſecure their ſtanding. They are left in this ſituation one day, to drain; then they are ſpread upon the graſs for one or two days, and after this they are laid in heaps, and covered over with haulm, ſtubble, ſtraw, or ſome other ſuch like covering, to make them ſweat. When the hemp or flax has ſweated enough, it is laid in heaps in the ſhade, and there dried: but theſe heaps muſt not be ſo thick, but that the air may penetrate a little into them. It is on this laſt operation that the good or bad quality of the hemp or flax thus managed chiefly depends. Both of them may be kept two or three years, and even longer, upon their reeds, after they have been prepared in the manner above directed; and when it is intended to break them, after this keeping, they are put into an oven properly heated.

In the common way, after the flax has been graſſed, it muſt be dried by heat, to make its reed break readily, and ſeparate the more eaſily from the bark. To guard againſt the danger of fire, this buſineſs is frequently performed in a place diſtant from any other building. The caverns, or hollows under hills, or rocks, before deſcribed for drying hemp, are alſo very proper for this purpoſe.

There are two general ways of drying flax. Some place againſt a wall, upon uprights and croſs pieces, a hurdle of which the bars are ſmall, and about two inches aſunder, and upon this the flax is ſpread four, five, or ſix inches thick: a ſmall fire, made of broken reeds of flax, is cautiouſly kindled under it, and care is taken to turn the hemp from time to time, that it may dry equally in every part: the flax-dreſſer takes off only that part of it which is at the ſide of the hurdle next the wall, then puſhes the reſt forward into its place, and fills with freſh flax the vacancy thereby made at the fore-part of the hurdle. This operation ſhould not be entruſted to any but a very attentive perſon, becauſe if the flame ſhould be ſuffered to riſe too high, it would ſet fire to the flax. It is true, indeed, that this ſeldom happens; and when it does, the loſs is not great, becauſe but a ſmall quantity of flax is laid together on the hurdle. Some ſay, that the ſmoke of the fire thus made of the broken reeds hurts the colour of the flax, and that this leſſens its price when it is ſold; but that the quality of the linen made of it is not at all the worſe, this diſcolouring being eaſily removed by bleaching.

The other method of drying flax is by putting it into a hot oven. The Livonians make their ovens, for this purpoſe, either of clay, brick, or hewn-ſtone. Thoſe which are built with clay, are ſometimes large enough to contain eight hundred bundles at a time: but it is more common to make them for only two, three, or four hundred. They are ſhaped like the ovens for an army, that is to ſay, they are very high arched. They require no greater degree of heat, which is given with dead wood, furze, broom, &c. than is juſt ſufficient to render the reed of the flax brittle; and the ſame of hemp, for the Livonians uſe them for both theſe plants, the bundles of which they ſet upright in them, and as ſoon as they take them out of the oven, they carry them to a kind of a mill, to be broken.

The Dutch build their ovens for drying flax within a large capacious chimney at the end of the building where the breakers and ſcutchers work. The uſual dimenſions of this building, which is well lighted, are, in the clear, thirty feet by fourteen; but it is ſometimes larger where great buſineſs is carried on, though ſeldom, if ever, leſs.

The

The dimenſions of the oven here generally are fifteen feet in depth, ten in breadth, and five feet in height: its roof is arched, its entrance, which is juſt large enough to admit a man with tolerable eaſe, is made to ſhut cloſe with a wooden door. This oven is not heated with wood, excepting at the very firſt; for after the workmen have begun to dreſs the flax, the broken reeds, and other refuſe parts which are beaten off it, and ſwept up, ſuffice to continue the heat, ſo that each parcel affords firing for the next, till the whole is dried. The Dutch kindle the fire in the oven ſome hours before the day's work is over. The ſweepings of the flax light eaſily, and the oven heats and cools again ſufficiently before the breaking, and ſcrutching is finiſhed. They fill it when they leave off work; and the next day when they return to it they find the flax dry and fit for breaking. The flax breaks beſt and moſt eaſily when it is a little warm and criſp: and conſequently the working it then is cheapeſt and moſt advantageous; and accordingly the Dutch never draw two bundles together from the oven, but take them one by one as they want them. It will, perhaps, be needleſs to obſerve, that when the oven is heated, it muſt be well cleaned before the flax is put in; for the leaſt ſpark will ſet the flax on fire, and this would be a conſiderable loſs, as the ovens hold a large quantity.

The famous M. Tſchiffeli, or Berne, in Switzerland, has obliged the public with a Memoir on the Culture of Flax, the ſubſtance of which we ſhall lay before our readers.

In his directions for the choice of ſeed, he ſays, it ſhould be of a bright ſhining brown colour, not flat, but thick and plump; ſhould crackle much when caſt on live coals, and ſhould ſink to the bottom almoſt as ſoon as thrown into water.

With reſpect to ſoils, this writer obſerves, that any may do for flax, provided it is not too wet, or too ſtoney, and has not too much ſand or gravel mixed with it: ſome, however, are to be preferred, particularly black earth, neither too ſtrong nor too light; and, in general, ſtrong land is to be preferred to light.

To prepare graſs-grounds and paſtures for ſowing flax, M. Tſchiffeli lays down the following rules:

The land ſhould, by the end of July at lateſt, be turned up in ſmall furrows, about two inches deep. Early in the month of September, a heavy harrow ſhould, in dry weather, be drawn over the field, in order to pulverize the ſoil; and the month following, if the land is not in great heart, it ſhould have a good dreſſing of dung, which being firſt regularly ſpread, ſhould, in dry weather, be ploughed in to the depth of ſix inches at leaſt, with narrow furrows, leaving the field rough all the winter.

In the following ſpring this gentleman obſerves, that as ſoon as the ground is dry, the land ſhould have a good harrowing; and about the middle of April, which is in Switzerland the ſeaſon for ſowing, it ſhould, in dry weather, have its third ploughing, ſomewhat deeper than the ſecond; and if the weather ſhould not immediately afterwards be favourable for ſowing, the land ſhould the ſame day be harrowed down ſmooth.

When flax is to be ſown on a fallow, the three uſual ploughings are to be given, obſerving only, that every ploughing is deeper than the laſt; and the dung ſhould be buried by the laſt, leaving it rough during the winter, and managing it as above in the ſpring.

When flax is ſown the ſecond year after a fallow, the land being dunged the preceding year, and in good heart no manure will be neceſſary; but immediately after harveſt it muſt be ploughed about two inches deep, to prevent the weeds from growing and impoveriſhing the ſoil. As ſoon as any weeds afterwards make their appearance, it muſt be well harrowed with heavy harrows, and about Michaelmas ſhould be ploughed in narrow furrows, about ſix inches deep, lying rough during the winter ſeaſon. The following ſpring the ridges ſhould be harrowed down, and afterwards laid ſmooth with ſmaller harrows, being in April ploughed for the laſt time.

Flax, M. Tſchiffeli remarks, thrives beſt upon land that has the preceding year borne a crop which ſhaded the ground, and prevented the weeds from growing; therefore good flax is ſeldom got after rye.

This writer very juſtly obſerves, that the quantity of ſeed to be ſown ſhould be proportioned to the nature and condition of the land, never leſs than two, nor more than three, buſhels to the acre. Light land ſhould be ſown earlieſt, but always after the dread of white froſts is over, and never in rainy weather, or when the ground is wet; a mild day is beſt for this purpoſe, when the wind is not in the north-eaſt, and dew may be expected in the evening.

It is beſt, our ſenſible huſbandman ſays, to begin to plough for ſowing after noon, the harrow following cloſe at the heel of the plough. A little before ſun-ſet, the ſeed is to be ſpread, beſt at three caſts, and the work left in this ſtate till the next morning, when, without fail, the ſeed muſt be covered with light harrows, or ſtrong rakes. If the ſoil is rather light, and the ſpring likely to be dry, it will be beſt to roll the land; and if it was not manured before the winter, ſome very rotten dung may be ſpread after the ſeed is harrowed in, and before the field is rolled.

It is better to uſe no dung at all than that which is not well rotted: ſoot and aſhes, hogs or cows urine, are good manures for flax, or in fact almoſt any thing that will not carry weeds on to the land.

When flax is grown to the height of about four inches, it may ſafely be weeded; but the precautions taken in Switzerland on this occaſion are worth notice. There the work is carefully executed, but with as much expedition as poſſible, the weeders going bare-footed into the field, and working as much as they can, either ſitting or lying down, heaping the weeds, and carrying them away every time they leave off working. The weeders ſhould alſo, if poſſible, always face the wind, by beginning at the corner of the field to which the wind blows, as in this method the flax will riſe the ſooner; and the work ſhould never be done in rainy weather, or when the ground is wet.

If the flax is to be propped, the beſt time to do it is at the time of weeding. To prop flax is to fix ſupporters, about the ſize of a man's finger, branched a little at the top, and about three or four feet long, at the diſtance of every three feet.

Flax ſhould be pulled in dry weather, in general, when the foot of the ſtalk begings to turn yellow, though the ſeed ſhould not be quite ripe. If the crop is not all of equal ripeneſs, the ripeſt ſhould be ſeparated, as, if all were to be graſſed together, the unripe part would be rotten before the other was ſufficiently graſſed: it is alſo

beſt

beſt to pull, though at one time, the longeſt ſeparate from the ſhorteſt. When it is all pulled, it muſt be ſpread on graſs-ground, or on a ſtubble, the crop-end of the ſtalk being laid to the ſouth, that the ſeed may ripen the better.

M. Tſchiffeli is of opinion, that when the quantity is large, it is beſt to ſeparate the ſeed by threſhing as ſoon as it is got in, in the following manner. The beds muſt be made pretty thick, the crop-ends of the ſtalk touching the wall of the barn; and over the feet of the ſtalks a heavy plank is to be laid, to prevent the flax from being ſcattered about in threſhing. The wall, by confining the workmen, will prevent them from ſtriking too hard, and thereby damaging the flax.

If the quantity of flax is ſmall, it may be rippled in the ordinary way, obſerving only that the handfuls be not too large. When the ſeed is ſeparated, it muſt be laid on a cloth, expoſed to the ſun for ſeveral days; and afterwards it ſhould be kept in a very airy place; but muſt be ſtirred every two or three days for three weeks. It may be kept in this condition two or three years, without the leaſt damage; but when once this ſeed is deprived of its capſule, it will ſcarcely ever keep above a year.

When the flax has been rippled, it muſt again be laid, but thinner than the firſt time, on a graſs-field that has been about a fortnight before mown, being ſpread, if poſſible, in dry years on damp ground, and in rainy years on dry land, but never on wet meadows. It muſt at this period be carefully turned every other day, if the weather is wet, or the dews heavy.

The time the flax is in graſſing, depends on the coarſeneſs or fineneſs of the ſtaple, the heat and the cold, dryneſs and wetneſs of the weather; but if, in bruiſing betwixt your fingers, the top of the ſtalk when it is dry, the harle or bark ſeparates eaſily from the woody part or boon, and this laſt is not tough, but brittle, the flax ſhould be taken from the ground, in order to be carried under cover as ſoon as it is dry.

The beſt method of drying flax for braking, this accurate writer ſays, is to dig a hollow place in the earth, two feet deep, three wide, and from twelve to fifteen feet long, lining it with ſtone, over which, at the height of about four feet, is fixed a griddle, or grating, conſiſting of ſmall poles, ſecurely made faſt to four or ſix piles, or ſtakes, driven into the ground.

The moſt proper fuel, we are told, for drying the flax, is either charcoal, or well-dried turf, as well becauſe they give an equal degree of heat, as on account of their not producing much of either flame or ſmoak.

When the workmen begin to brake the flax, they muſt go on briſkly; for it ſhould be done whilſt it is hot from the grating, and ſhould be effected by an equable motion, beginning at the crop-end.

In this manner does the ſenſible and patriotic Monſ. Tſchiffeli ſay that flax ſhould in this country be cultivated and managed; and, if we are not greatly miſtaken, the method might, with very little variation, be to advantage adopted in the Britiſh iſlands.

As different countries have different methods in cultivating the various productions of the earth in general; ſo thoſe relating to flax, in particular, are greatly deverſified. We have, therefore, given under this article every thing we thought worthy the reader's attention. The following is the method practiſed in the Mahera, a diſtrict of the county of Roſcommon in Ireland; and was wrote by Mr. John Irwin, a gentleman who has long cultivated flax there with ſucceſs.

Of the Cultivation and Management of Flax in the Mahera.

The poorer ſort of people in the diſtrict I live in, are ſo indigent, that they are almoſt in a ſtate of ſlavery. Indeed, within theſe laſt forty years, they have much recovered from their bare and naked condition, owing in a great meaſure to the conſiderable extenſion of the linen manufacture.

Their chief riches conſiſt in their annual crops of flax, corn, and potatoes, in order to pay their rents, which they help off with day labour; a moſt galling article to them; for, as to cattle, few of them have any, or but a milch-cow or two at moſt, which are appropriated for nouriſhing generally a numerous iſſue. The calves, which induſtry ought to be let remain with them to increaſe their funds, or to clothe their families, a rapacious landlord ſeldom wants a pretence of appropriating to himſelf. Theſe people then, from neceſſity, it is evident, muſt be perfectly verſed in the cultivation of flax and potatoes; and they would ſucceed very well as to corn, had they ſurmounted a few old prejudices reſpecting the form or make of their implements, and the methods of uſing them. It is, however, from ocular knowledge of their proceedings, in my work and their own, that what I now communicate to you is founded.

The ſoil about Oran, being ſtrong, deep, and moiſt, with a clayey loam moſtly at bottom, yields excellent flax. It is here ſcarcely ever produced immediately from the ley. The general practice is as follows: a parcel of ley land in good heart, that is, which has not been ploughed for many years, is proclaimed to be ſet to graſs potatoes (otherwiſe ſpaddane, a very miſtaken practice, eſpecially if a deep ſoil, if not to be ſanded, or if a light, if not marled, or limed, or otherwiſe manured) for this land the poor are charged from three pounds to five pounds per acre, ſanding not always included: a moſt unconſcionable price?

They generally bargain for two ſucceſſive crops; and it is for their benefit, as alſo for that of the land, to have it ſanded, becauſe it ſtrengthens it the better to ſtand a continuation of tillage, and to come the ſooner to turf, and yield a good coat of graſs, when let back into the ley; but the ſky-farmers (thoſe who hold at rack-rents) are moſtly ſo greedy for grain, that it is with reluctance they agree to ſanding, as it abates fourteen ſhillings per acre of their price. When land that requires it is not ſanded previous to this kind of tillage, it is doing it great prejudice; but farmers are not always ſollicitous about this matter, eſpecially on ſhort leaſes.

Land properly ſet in this way ought to be ſanded at leaſt a year before ſetting, that it might have proper time to penetrate into the earth, and impregnate it with its ſalts; but they are ſuch bad farmers about me, that they ſet, ſand, and plant their potatoes almoſt at the ſame time. Even in this bad way the land ſhould be ſet and ſanded (or otherwiſe manured) at leaſt in November, and the potatoes planted the March following at fartheſt: but I have ſeen land not ſanded till March or April, and not ſowed till towards the end of May, (a palpable blunder;) yet this land has yielded a tolerable crop, owing to its great natural fertility; for the ſand becomes of little uſe, if the land is turned up ſoon after it is freſh laid on. This does much hurt in the country; for ſuch land, after it is let out for a long ſeries of tillage, (ſuppoſe fifteen years) is a long time recovering itſelf, and

that

PLATE XVI.

The foot Machine for Breaking & Beating Flax & Hemp: Invented by M.

End Elevation.

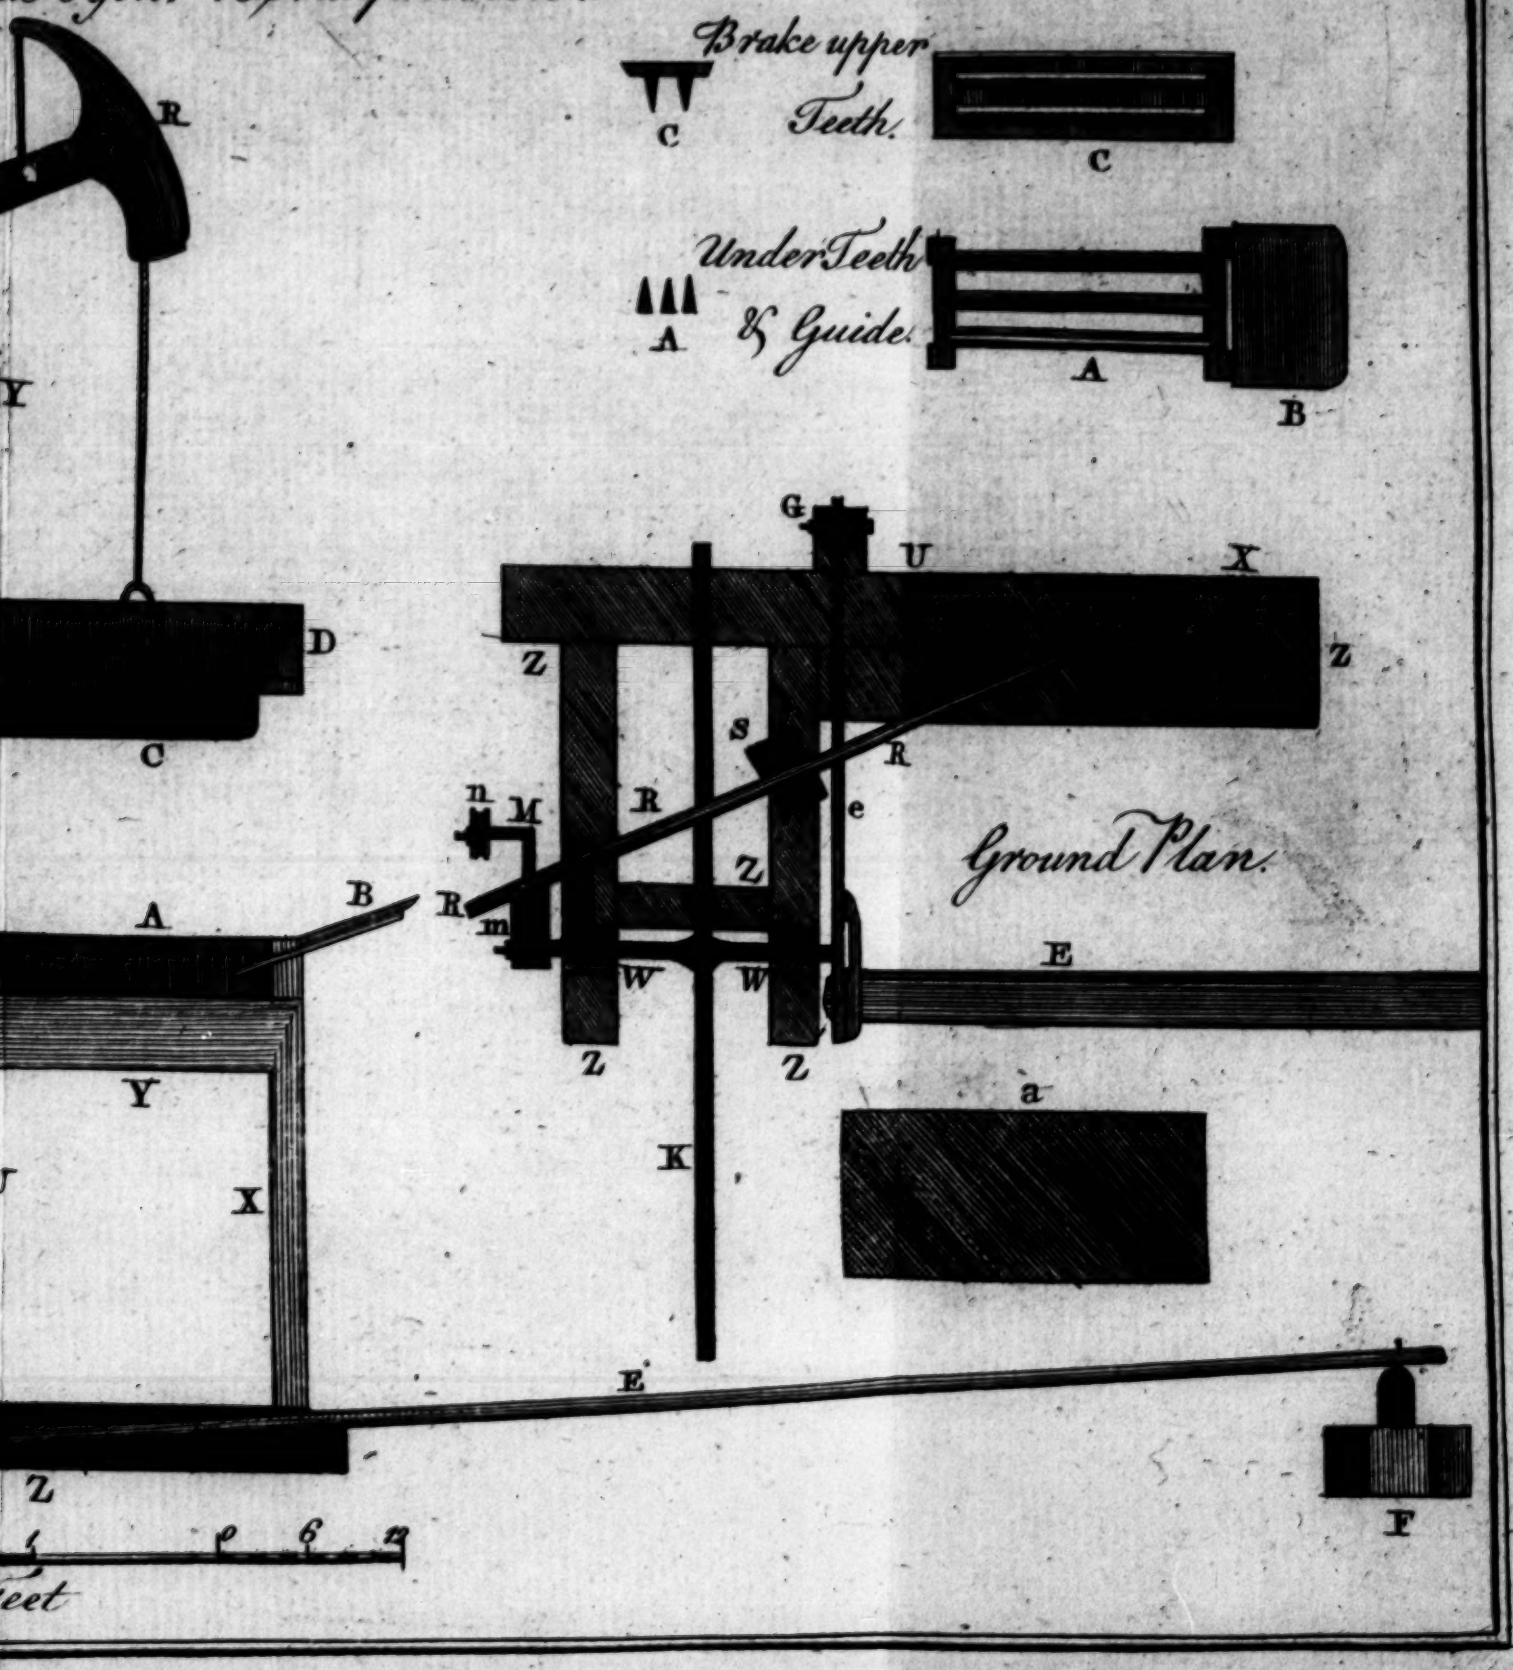
Scale of Feet

ed by Mr. R. Macpherson.



that which is ſpaddanized out of the ley, and not gravelled at all, unleſs of a moſt ſuperior rich kind, is doubly injured.

The potatoes ſhould be dug towards the end of October, or beginning of November at fartheſt, (froſty weather excepted) to make room for a crop of bere, or a crop of flax, the ſpring following; if for flax, the land ſhould get a deep ploughing before Chriſtmas, to benefit of the winter manure, ſuch as froſt, ſnow, air, &c. and a croſs ploughing the beginning of February; and towards the end of March, it ought to get another ploughing in the track of the firſt; then the ridges to be harrowed down as fine and as flat as poſſible, and the ſeed ſown in, and lightly covered with another gentle harrowing; for the ſeed is not apt, from any cauſe that I have obſerved, to be diſturbed in the ground.

In this ſituation it ſhould be left till June, then weeded. Some weed it when four or five inches high; but treading it ſo young hurts it; and this weeding is of no uſe, for it muſt be weeded again before pulling, eſpecially in deep chiltern countries, where weeds get a-head much more than in light gravelly ſoils. In theſe the flax is always ſhorter and finer, and the ſeed in leſs quantity; but the Iriſh ſeed, though it is often impoſed for foreign, is never ſo good: for example, the firſt year's return of foreign ſeed will produce a middling good ſort of flax, whereas the ſecond return will not. To ſow the ſeed even ſhould be moſt carefully attended to: a commonly ſkilful hand will with eaſe caſt it properly, the method being ſo well known. Sixteen pecks of ſeeds at twelve quarts to each peck, is a proper quantity for an acre of good light ſoil. In my deep grounds I have known fourteen pecks to be ſufficient.

The ſeed now much uſed in Ireland is the Plantation, but the better ſort of the Baltic or Riga ſeed I would prefer. The Dutch agrees worſt of all with our climate. The choice of it is eaſily known. The women are ſurpriſingly ſkilful in every thing that regards this plant: one of them will ſhut her eyes, put her hand into ſeveral hogſheads of flax ſeed, and fix upon that which is beſt; but they have marks from preſſing it to oil between their fingers, ſo as to obſerve the edges, and from taſte, ſmell, and view, without requiring to make the other common experiments; whence they are ſeldom deceived; not but the merchants play them a thouſand tricks in this article, which is become very lucrative of late years, from the vaſt demands there are for it.

The heavy, pale reddiſh, or rather clear brown looking ſeed, being thick and ſhort, and oily in the feel, is the beſt. Sometimes, among ſome parcels of the ſeed, there are certain mixtures, by which predications the women immediately eſtimate the quality of it. The old Iriſh ſeed, of which quantities are ſtill ſown, is the worſt of all; the returns are extremely bad, and the flax but indifferent for uſe.

Two crops ſucceſſively are common in deep rich lands; but as flax is a great drawer, they are not the better for it, as it greatly retards their coming to graſs.

We always ſow flax after potatoes or corn, (bere) and, if proper care be taken in the preparation of the land, find it to anſwer well. How far better it may be immediately out of freſh land manured, I will not take upon me to ſay: ſome writers recommend this method; but it would never anſwer with our poor people. I have ſeldom known flax to be raiſed immediately from manured grounds: mine being rich, deep, and moiſt, and properly wrought to return a firſt crop of ſome other article, yields afterwards admirable flax. Where different ſoils can be had in the ſame diſtrict, it is needleſs to obſerve, that the richeſt and ſtrongeſt, with a clayey loam at bottom, is beſt: the nature of this plant requires ſuch, being a great drawer of the nutritive parts of the earth; but, on the other hand, there is a medium to be followed in this, as in moſt other things: land may be made too rich for flax, which will undoubtedly lodge it, that is, occaſion its prematurely lying flat to the ground: this prevents its ripening, conſequently occaſions great waſte of it, total loſs of ſeed, and what is recovered of it manufactures but indifferently, and ſtands the teſts of uſe worſe: however, there is much of this ſort ſpun into yarn by the poor, and impoſed for good on the eagle-ſighted yarn-buyer, notwithſtanding his great vigilance.

If middling good land, whether in the ley or not, be fallowed early in the ſummer, and gets the proper tilth till the March following, when it is to be ſown, there is no doubt but it will yield an excellent and abundant crop of flax. Land cannot be ploughed too often, or made too fine, for this purpoſe. Flax ought to be ſown and pulled in dry weather.

It is ripe in my neighbourhood, generally ſpeaking, not till the beginning or middle of Auguſt, and ſometimes later, when late ſown: the better ſort of huſbandmen think it is not neceſſary to ſow it earlier than Good-Friday: about that time moſt people begin.

The poor people have ſeveral marks by which they know when it is fit for pulling: the degree of brownneſs of the colour is the chief, and is a ſufficient guide to any perſon. The men and women, promiſcuouſly ranged in a row a-breaſt, pull it expeditiouſly enough, eſpecially if they are a little refreſhed with ſome of the good things of this life, and lay it on the ſwarth. If there be danger of rain, they bind it the ſame evening into ſheaves, and ſtook it, putting commonly eight ſheaves in every ſtook. Here it is ſuffered to remain for ſome days, till it is ſufficiently dry to remove.

The poor, from neceſſity, proceed to manufacture it immediately, by rippling of the rows, and watering it, &c. But my method is as follows. After I let my flax ſufficiently ſeaſon in the field, ſo as to prevent the danger of heating, which deſtroys it, I draw it into my haggard, ſtack it, and thatch it well. Thus I let it remain till the next ſowing time, (March) when I ripple it and water it, and, if I have leiſure, proceed to dreſs it; if not, make it back into a ſtack, and let it lie ſo, without any hazard of danger, as long as convenient: or, (another way) ſoon after pulling, it may be rippled, watered, and ſtacked, ſo as to be ready for dreſſing the ſpring following. But I chuſe the former method, becauſe I thereby preſerve the ſeed, and ſell it, if I take a little care, equal to the foreign, which will go a good way in reimburſing me my expence: it is true the quantity of flax will be ſomewhat diminiſhed for remaining ſo long unwatered; but then it makes ample amends in meliorating it; for I have obſerved, that the flax thus managed dreſſes and manufactures much better, and when in linen, it wears beſt. But the impatience of our Iriſh ladies, who are the conductors of this branch, from the time the flax is over ground, till made into linen, is ſuch, that they do not reliſh delays of this ſort, though infinitely the beſt method of proceeding.

For watering flax, clear ſtagnated pools or canals, or ponds, are beſt, provided there are no fiſh, as it kills them: ſprings and running waters muſt be avoided. To ſink it under water is proper, and let it lie about three weeks, more or leſs, according to the quality of the flax, and the condition of it at putting in.

About me the poor people ſtill perverſely will water it in bog holes, becauſe they think the water cannot be too ſoft, and that the banks being unincumbered with long graſs, facilitate the drying of it.

When it is brought home (as they have no ovens) they fix a large hurdle horizontally by a ditch ſide about four or five feet from the ground: on this they lay a parcel of flax, and underneath make a large turf fire, and keep conſtantly turning it.

They judge it fit for the brake, by rubbing a parcel between their hands, and finding the prickles to detach themſelves eaſily from the flax.

The braking is a very laborious part: it is pity that about where I live there are no engines contrived for this purpoſe, as it would ſave great expence in labour. This part of the proceſs ought, properly ſpeaking, to fall ſolely to the ſhare of the men; but the women as commonly do it, which I think very unſeemly, and ſtill more ſo to ſee a man ſcutching and hackling flax, which is equally as common with us: but the women always ſcutch mine, and I find do it beſt, as I order them refreſhment, it being merry-making time, (though but ſhort) like vintage, or ſheep-ſhearing time.

The conſtruction of the brakers I need not explain; they are ſimple engines, and known to every body. The broad ſcutch is beſt, as it hurts the flax leſs: it ought to be made of well ſeaſoned oak, to be light, that the women, who are dexterous at it, may manage it more eaſily.

A great deal depends on the ſkill of the hackler, who ought to be very expert and knowing in dividing it properly, and in arranging the ſorts according to their different fineneſs. I have had ſome hacklers manage this matter ſo well, that out of the very tow they produced I had good linen for common uſe. I had other hacklers, who, inſtead of preparing my flax to ſpin to eight or ten dozen of yarn to the pound, of which it was capable, prepared it ſo badly, as to produce me only from four to ſix dozen yarn.

To the ſpinners we keep in our houſes we generally give from thirty-five to forty ſhillings a year: theſe ſpin from four to eight dozen yarn; but if they ſpin finer, they are entitled to get a gratuity in addition, or higher wages. There are girls in plenty in the north of Ireland (where the manufacture moſt flouriſhes) who ſpin ſurpriſingly fine, and many of them with both hands at once, at wheels adapted for the purpoſe; but ſcarcely any of theſe ever come into the parts where I live.

As to the reſt, from the time the yarn is ſent to the weaver, till it is brought home from the bleach fit for uſe, it forms a particular proceſs in itſelf, and ſhall be communicated to the public, when more ample leiſure will permit. However, before I diſmiſs this ſubject, it may not be improper to make a few detached obſervations to illuſtrate ſtill more what I have already ſaid.

There are various ways to know good ſeed, which is one of our moſt eſſential objects. Firſt, To diſcover its thickneſs, by taking ſome grains, and ſqueezing them between the fingers, until the white edges of the inſide pulp or grain are forced to appear. To eſtimate its goodneſs by its weight may be eaſily done, by throwing a handful into water, and if good it will ſink quickly. To prove if it be oily, throw a handful on the fire, and if, as ſoon as it touches the coals, it burns up and crackles, its goodneſs may be depended on. But no ſeed of Iriſh growth, as I ſaid before, will thrive well a ſecond year in any of the ſoils in my neighbourhood; nor will the ſame ſoil anſwer for more than two ſucceſſive ſeaſons, without the intermediate occupation of other crops procured from manures.

As the culture of flax lays down land very ſmoothly and well, if you chuſe to have your land let out, you may ſow graſs-ſeeds with a light roller, or buſk, in ſome little time after your flax is in the ground: they will not hurt it; and by this means you will have a full coat of graſs the ſame ſeaſon, which otherwiſe perhaps would not be the caſe for two or three ſeaſons, flax being a great impoveriſher.

When the flax is a clear yellow, or a clear brown, ſomething reſembling a lemon colour, and begins to drop its leaves, it ſhould be pulled; but never when it is green, though often done, which is a very deſtructive method, for in this caſe it loſes conſiderably in quantity and quality, both with reſpect to flax and ſeed. Thoſe who imagine pulling it green will make it yield the finer linen are miſtaken: they need only conſult the method of the Flemings, who ſuffer it to remain the longer in ground, the finer they want it to prove for their laces, cambricks, &c. Care, however, ſhould be taken not to let it remain too long in ground, as this makes it work badly, yield bad yarn, and not bleach ſo well.

I have kept my flax in ſtack in my haggard ſome two or three ſeaſons, and never found it was damaged by vermin, though I know there are preventatives laid down by ſome writers for this purpoſe.

If the ſeaſon be moiſt, there is no ſtacking it with ſafety, till it remains unheaped a conſiderable time in the barn, as the leaſt heating is certain deſtruction to it.

No land can be too good for flax, if the ſeed be duly proportioned to it. If the crop fails on a rich and ſtrong ſoil, it has too much ſeed; for it ſhould not be ſo thick, but that every ſtem may have the benefit of the ſun and air to fortify it. *Muſeum Ruſticum, vol.* I. *page* 5.

A ſhort Account of the Advantages of the new Machinery for breaking, ſcoutching, and beating Flax and Hemp, invented by Robert Mac Pherſon, Aſſiſtant-Secretary to the Commiſſioners and Truſtees for Improvements in Scotland.

The breaking of flax by the Dutch hand-brake (which is the beſt old method of breaking) the ſcutching with ſtock and hand, and beating with hand-mallets, being laborious, tedious, expenſive, and requiring many hands, it was thought a valuable improvement, when, ſome years ago, a water-mill was invented, by which theſe operations are performed with more eaſe and expedition. But in ſome parts of the country, a ſufficiency of water and water-fall is not to be met with; in other parts where theſe are to be had, lint-mills are not erected, on account of their heavy expence; and where-ever erected, they are found liable to the following inconveniencies. Firſt, The expence of fitting up the mill, making dams, the aqueduct, &c. and keeping theſe in repair, is great; and much damage happens by fire, and by water-floods. Secondly, In Scotland, it has hitherto been found, that on account of the ſcarcity of hands, and difficulty of dreſſing in the old hand-methods, flax never was raiſed in conſiderable quantities, until the country people found the conveniency of a mill in their neighbourhood; and therefore the firſt fitter up of a mill in a part of the country where there was none before, could not for years expect buſineſs adequate to his out-lay of money. This circumſtance

cumſtance obliged the linen board in Scotland to defray part of the expence of fitting up many of theſe mills. Thirdly, This mill is extremely dangerous to the workmen; many have loſt arms by it, ſome their lives, and the nature of the work there is otherwiſe remarkably unhealthy. Fourthly, This mill is ſo conſtructed, that the ſtroke of its ſcutchers is ineffectual, unleſs they are moved with a degree of violence, that nothing leſs than the utmoſt dexterity and cloſeſt care can prevent from deſtroying a very conſiderable part of the flax; and as that ſkill and unremitted attention cannot be expected among a number of common day-labourers, the great waſte of flax always attending theſe mills is eaſily accounted for, eſpecially as unſkilful hands are often employed; for being called to this work only in winter, the lint-miller muſt content himſelf with labourers that, at the beginning of the ſeaſon, are not otherwiſe engaged. Fifthly, The carriage of the rough flax to mills at a diſtance, the delay there, ſometimes for months, till others be ſerved, during which time the flax muſt lie without doors: damage, embezzlement, &c. theſe are much complained of; and, with the waſte before-mentioned, have in general ruined the character of theſe mills. Sixthly, The expence of flax-dreſſing is ſtill kept high, becauſe the proprietor of the mill muſt have a large rent, eſpecially as his outlay upon it is extenſive; the miller muſt have a living; and the workmen extraordinary wages for ſuch dangerous and unhealthy work. In ſhort, it has become very doubtful, whether, upon the whole, theſe mills have not been more hurtful than beneficial to the manufacture.

The new water-mill for dreſſing flax and hemp, invented by Robert Macpherſon, removes part of theſe inconveniencies. For, 1. It is much leſs waſteful of the flax: as much ſo, it is preſumed, as water machinery can poſſibly be. It not only yields more flax from the ſcutch, but the flax dreſſed by it yields ſtill more from the heckle. 2. It is fitter for dreſſing long hemp. 3. It is no way dangerous nor unhealthy to the workmen. 4. It requires a leſs expenſive mill-houſe, and leſs annual repair. 5. It requires much leſs water. 6. For one, two, or a few workmen, the parts of its machinery which dreſs the flax or hemp, may be joined to the movement of a corn-mill, or any other mill, by a ſmall iron-axle, or by rope and pully, through any wall or partition, at a ſide, above, or below.

Where much buſineſs in the beating way is to be done, the new machinery with water or a horſe, gives entire ſatisfaction. But ſcutching proves an operation that requires more judicious management than can be expected at a public water-mill. A lint-miller, who dreſſes flax for others, finds his profit in the diſpatch made by the great velocity which can be given to the ſcutchers by a power of water; but the proprietor of the flax loſes more by the waſte occaſioned by that velocity than the miller gains by the greater diſpatch. In ſhort, the dreſſing of flax by any expenſive public water-mill remains ſtill liable to many of the inconveniencies mentioned in the firſt part of this paper.

The foot-machines (likewiſe invented by Robert Macpherſon) it is preſumed, obviate all theſe inconveniencies, and go far towards bringing flax-dreſſing to perfection. For, 1. They waſte the flax or hemp as little as the hand methods of dreſſing. 2. They are much more expeditious, and as much ſo as dare be attempted without deſtroying a conſiderable part of the flax or hemp, which above every thing elſe ought to be avoided. 3. The working with them is not ſo laborious as the hand methods. 4. They are not dangerous to the workmen. 5. They are not too bulky for general uſe: they are portable upon a cart, are of ſmall expence, ſimple conſtruction, can be made by any good carpenter and ſmith, and each machine is wrought by a ſingle perſon.

With theſe foot-machines any perſon may have his flax or hemp dreſſed under his own eye, by his own ſervants, and at times when otherwiſe they would be idle, in the dark afternoons of winter, when the lanthorns uſed by hecklers will prevent accidents by fire, and in the day-time when bad weather hinders working in the fields. Thus the dreſſing of flax and hemp becoming eaſy, the raiſing of theſe crops, of all the moſt profitable to the farmer, and to the country, will become more general; many will have their flax or hemp dreſſed by their own ſervants, without expence; and when others are hired to that work, the expence muſt be much leſs than by the hand methods, as the machines are greatly more expeditious. The water-mills are not taken into this compariſon, becauſe their waſte of the flax or hemp overbalances the profit of their greater diſpatch.

The importance of this new machinery to Britain, Ireland, and the colonies, muſt appear very great, when the following particulars are conſidered.

	l.
The value of the flax and hemp raiſed in England yearly cannot be reckoned leſs than —	250,000
It appears from the Cuſtomhouſe accounts, that there was imported into England, from Chriſtmas 1762, to Chriſtmas 1763, 100,997 buſhels of Linſeed. In the fens about Lincoln-Waſh, thirty towns and villages have yearly about 6000 acres of flax and hemp. There are likewiſe ſome thouſand acres of theſe crops yearly in the marſh-lands on the borders of York and Lincolnſhires. The town of Snaith in Yorkſhire has the greateſt flax-market of any place in Britain.	
The value of the flax and hemp raiſed in Scotland yearly is calculated about — — — —	190,000
There is imported into Scotland about 60,000 buſhels of linſeed yearly.	
The value of the flax and hemp raiſed in Ireland yearly may be reckoned about — — — —	500,000
The linen manufacture there is about double that in Scotland, and moſtly made of their own flax.	
Sum of theſe — — —	940,000
The expence of breaking and ſcutching that 940,000 pounds worth of flax and hemp may be reckoned	150,000

pounds; one half of which, or 75,000 pounds per annum, muſt come in time to be ſaved by the uſe of the new machines; for the new ſcutcher does more than double the work of the old hand-ſcutch in the ſame time. The new brake is not ſo advantageous in that reſpect; yet the inventor thinks he errs on the ſafe ſide, when he ſtates the new brake and ſcutcher both together, as doing only double work.

The colonies in America are now encouraged to raiſe flax and hemp, by a parliamentary bounty in Britain.

The great advantages of raiſing our own ſeed, flax, and hemp, inſtead of providing them from foreign countries, need not be here repreſented. What is at preſent imported appears from the cuſtomhouſe accounts as follows: and it cannot be doubted but the aforeſaid new ma-

chinery will be the means of increaſing our own growth, and conſequently decreaſing the foreign importation.

The linſeed imported into England is annually	l.
about 100,000 buſhels, reckoned in value	
about — — — — — — — —	40,000
Into Scotland, about 60,000 buſhels — —	25,000
Into Ireland, about 80,000 — — — —	34,000
Flax and hemp into England, about — —	700,000
Into Scotland, about — — — — —	120,000
Into Ireland, about — — — —	
Sum of theſe, excluſive of the blank for Ireland	919,000

And that there can be no want of market for an extenſion of our linen and hempen manufactures (which the new flax-machinery muſt greatly promote) appears evident from the extenſive importation of theſe manufactures from foreign countries; for, according to the Cuſtomhouſe accounts, there is annually imported into England, from the continent of Europe.

	l.
Linen-yarn, of value about — — — — —	200,000
Linen-cloth, of value about — — — —	1,500,000
And thread, lace, ſail-cloth, cordage, ſacking, &c. the amount of which muſt alſo be conſiderable.	

Explanation of Plate XIV. *repreſenting the* FOOT-MACHINES *for* BREAKING *and* BEATING FLAX *and* HEMP.

Of the FOOT-BRAKE.

A The three under-brake teeth, or ſwords, ſeventeen inches long, three inches deep, one and a quarter inch thick at back or bottom, a quarter of an
B inch at edge, the edges two and three quarters inches aſunder at the end next the guide B, and two inches aſunder at the other end.

C The two upper teeth, about an inch ſhorter than the under teeth.

D The brake-mallet, about thirty-three pounds Engliſh weight.

E, e. A compound foot-treadle. E is eight feet four
F inches between the fulcrums, raiſed at F eight inches above the ground (or rather five inches higher than the ſtance of the workman.) e is two feet four inches between the fulcrums, and is raiſed
G at G eighteen inches above the ground; that is, fifteen inches higher than the ſtance, of the workman.

H The ſword or upright timber-rod which turns the wheel by the treadle-crank.

I The treadle-crank, of ſeven and a half inches radius.

K The fly-wheel, four and a half feet diameter, above ſixty pounds Engliſh weight. As here repreſented it is beat or caſt-iron, but it is alſo made of timber.

L Braſs cods or buſhes.

M, m The lifting crank. m is fixed firm upon the axle of the fly, while the crank M, about eight inches radius, plays freely round the axle. In poſition firſt, m begins to take round the crank (which by the lever R pulls up the mallet:) when it comes to poſition ſecond, the mallet is again at liberty, and by its weight pulls up the crank (faſter than the fixed pieces move) into poſition third.

N. B. The treadle-crank is advanced about one eighth part of the circle before the lifting crank.

a A ſmall pulley, which turns eaſily round on the end of the crank, and to which a rope is fixed.

O A piece of timber which prevents the rope from falling in upon the axle, but which ſhould not rub againſt the rope in its coming down.

P Here the rope paſſes between two friction-rollers, which are ſo placed that the rope comes down there four inches, or half the radius of the lifting crank, or the ſide of a plummet-line croſſing the center of the wheel; that is, to the ſide on which the crank turns when it pulls down the rope.

Q A pillar, which ſerves only to ſupport the guard for the rope O, and the friction-rollers at P.

R The lever.

S The lever-pillar.

T Part of the mallet-frame.

U Two pillars which guide the brake-mallet.

V An iron ſpring which receives the leap of the mallet, and throws it the quicker down.

W The pillars which ſupport the fly.

X, U The pillars which bear the brake-teeth and mallet.

Y Spur and croſs, ſupports of the pillars.

Z The bottom frame-piece.

a A broad ſtool upon which the workman ſtands, three inches above the ground.

The brake-teeth are made of good beech or planetree, the brake-mallet of planetree, aſh, elm, birch, or oak; the ſword, or upright timber-rod between the treadle and the treadle-crank, of beech, planetree, or birch; and the lever of beech, aſh, or oak. The fly-wheel, if timber, ſhould be made of oak, aſh, beech, elm, or planetree. All the other parts of timber worth mentioning may be made of fir.

Of the FOOT-BEATERS.

The before-mentioned brake may at any time be converted to a beater of flax and hemp, by removing the brake-teeth, and putting in their place flat boards. In the upper of theſe boards may be driven thirty-two nails, the head about three quarters of an inch long, and the point of the head about a quarter of an inch diameter; the points of the nail-heads may be placed one inch clear aſunder, and in the order marked B, at equal diſtances, as in this way any of the nails may moſt eaſily be drawn out in repairing the mallet. An iron hoop about the mallet will prevent its burſting with the indriving of the nails.

For the ſole purpoſe of beating flax and hemp, the narrow end of the mallet is placed toward the workman; and where there is much work in that way, the mallet and fly may be made heavier, and then two or more workmen can work together upon the foot-treadles, which may alſo be made equally long.

Plate XVII. Fig. 1. repreſents the ſcutching machine, where *b* B G is the foot-board; D, D, ſcutchers; Q, the center of the iron wheel C, C, Q; S, the upright piece, or ſcutching ſtack; A the piece on which the hand reſts in order to ſcrutch the flax. The machine is put in motion by the nunch at M, which is moved by the foot-board.

We have been the more particular in our account of the various methods uſed in cultivating and dreſſing flax, becauſe it is an article, which, with proper encouragement, may become of the utmoſt importance to theſe kingdoms; and therefore, we were perſuaded that we could not do a more acceptable piece of ſervice to the huſbandman, than

by

by giving the various methods at full length, though we are conſcious that in doing this the reader will meet with ſome repetitions, which could not be avoided without curtailing the whole, and conſequently rendering it leſs valuable.

FLAYL. *See* FLAIL.

FLEABANE, or *Fleawort*, the name of a perennial weed common in paſtures, the ſtalk of which is round, bending, ſolid, and heavy. The leaves are oblong, ſharp-pointed, wrinkled, downy, and embrace the ſtalk on which they grow very thick without any regularity. The flowers are yellow, radiated, and incloſed in a flower-cup, made of narrow ſcales like briſtles.

FLEAK, a gate ſet up in a gap.

FLEAWORT. *See* FLEABANE.

FLET-MILK, milk that has been ſkimmed, or had the cream taken off.

FLOATING *of Meadows*. *See the article* MEADOW.

FLOTE-FESCUE *graſs*, an excellent graſs for cattle, growing in watery places.

The flote-feſcue affords excellent feet for horſes. Mr. Stillingfleet, quoting a piece publiſhed in the Amæn. Acad. vol. III. entitled *Plantæ Eſculentæ*, takes notice, that the author of it ſays, article 90, "That the ſeeds of this graſs are gathered yearly in Poland, and from thence carried into Germany, and ſometimes into Sweden, and ſold under the name of manna-ſeeds. Theſe are much uſed at the tables of the great, on account of their nouriſhing quality and agreeable taſte."

Our ingenious countryman, in his addition to this paſſage, has the following words: "Mr. Dean, a very ſenſible farmer at Ruſcomb, Berkſhire, aſſured me, that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered by a kind of graſs that maintained five farm-horſes in good heart, from April to the end of harveſt, without giving them any other kind of food, and that it yielded more than they could eat. He, at my deſire, brought me ſome of the graſs, which proved to be the flote-feſcue, with a mixture of the marſh-bent. Whether this laſt contributes much towards furniſhing ſo good a paſture, I cannot ſay. They both throw out roots at the joints of the ſtalks, and therefore likely to grow to a great length. In the index of dubious plants, at the end of Ray's Synopſis, there is mention made of a graſs, under the name of *gramen cannium ſupinum longiſſimum*, growing not far from Saliſbury, twenty-four feet long. This muſt, by its length, be a graſs with a creeping ſtalk; and that there is a graſs in Wiltſhire, growing in watery meadows, ſo valuable, that an acre of it lets for from ten to twelve pounds, I have been informed by ſeveral perſons. Theſe circumſtances incline me to think it muſt be the flote-feſcue; but whatever graſs it be, it certainly muſt deſerve to be enquired after.

"There is a clammineſs on the ear of the flote-feſcue when the ſeeds are ripe, that taſtes like honey, as I have often found; and for this reaſon, perhaps, they are called manna-ſeeds.

"Linnæus Flor. Suec. article 95, ſays, that the bran of this graſs will cure horſes troubled with bots, if kept from drinking for ſome hours." So far the very ingenious Mr. Stillingfleet.

From what has been ſaid above, we may conclude, that the flote-feſcue is one of the beſt graſſes that we can cultivate for the uſe of our horſes, and the more eſpecially, as it appears to thrive beſt in wet, low meadows, where many other graſſes would not grow.

There are at Claſton-Lodge, in the county of Eſſex, not far from Thorp, ſome low meadows, which are every year flooded for months together during the winter ſeaſon: theſe meadows are covered with a graſs of a remarkable fattening quality; for when old cows have been turned into them, though they were ever ſo poor and low in fleſh, they have in a very ſhort ſpace of time grown as remarkably fat; and when killed, their meat would appear as fine, and taſte as well, as that of any ſteer or ox; therefore it is reaſonably to be ſuppoſed, that the graſs growing in theſe meadows is no other than that of the flote-feſcue.

FLY, in turnips. *See* TURNIPS.

FLY, in ſheep, a ſpecies of maggot very troubleſome to that animal. The reader will find an infallible method to deſtroy theſe troubleſome inſects under the article SCAB *in Sheep*.

FOAL-TEETH. *See the article* AGE *of a Horſe*.

FODDER, hay, ſtraw, haulm, &c. given to cattle.

In the foddering-yards of backſides, or other out-houſes, to have ſeveral diviſions, over and above what is conſtantly uſed, has great conveniencies in it; one of which is, that in them you may diſpoſe of a two-yearling cow, or another cow, at the time of bulling; not only to keep them from a bull, but from the other beaſts alſo, that would be leaping ſuch a cow, whereby they may hurt each other, &c. eſpecially cows forward with calf will be apt to warp by leaping a bulling-cow.

The open winters make hay the deareſt, if a hard froſt and ſnow come at the fore-hand of them; for if once cattle come to fodder, they muſt be held to it, or they will receive great damage. In waſhy weather all the hay that can be given to cattle will not make them thrive, but in dry froſty weather they will thrive with their meat very well.

Mr. Liſle ſays, that he let his cows go at large from their foddering-yard, during the winter, and ſo continued till April, when they fed on ſome graſs; and thoſe that had calved, he foddered with hay: the conſequence of which was, that by the middle of April his cows would not ſtand to eat any ſtraw at all, but were, during the months of March and April, ſo weaned from ſtraw, by baits of graſs and hay, that they fell off from the ſtraw quite, and grew much leaner, and worſe in fleſh than they had been, and apparently worſe than the farmers cows, which were, after the winter months, wholly pent up to their ſtraw, and to the pond.

All ſorts of cattle that chew the cud, as ſheep, cows, &c. care not to graze after each other, nor to eat one another's leavings in the foddering-yards, but cattle that do not chew the cud will eat after thoſe that do, and *vice verſa*.

Pliny tells us, where hay was ſcarce, it was uſual to feed their cattle with chaff and barley-ſtraw. Of chaff, ſays he, that is the beſt ſort, which is the thinneſt and ſmalleſt, and neareſt to duſt; the beſt therefore is from millet, the next from barley, and the worſt from wheat, except it be for hard-labouring beaſts.

On ſound experience I am convinced, ſays Mr. Liſle, that in our hilly-country we ought not to have any dependence on ſending our cattle out of the foddering-yard to graſs before the middle of May, and therefore

we ought to be provided with winter fodder for cows accordingly.

At the beginning of winter, ſuppoſe the latter end of October, and a great part of November, while cattle ſtill continue out in the field at graſs, it is very neceſſary to fodder them early in the morning, while the hoar-froſt hangs on the graſs, which they will not eat kindly off till the ſun has warmed it.

The ſtraddling racks are beſt for foddering, if made ſtrong enough, that is, ſo as not to be over-turned; for theſe racks may be lifted up as the dung mixen riſes, which thoſe fixed in the ground cannot be.

It is a practice in many places, to tie their cows up to a rack to fodder; but if a perſon would rightly conſider the places where it is done, we ſhould find it only uſed where the fodder is good, being either hay, or very good ſtraw; but in the hill-country of Hampſhire, where the cattle have ſtraw fodder only, and that not ſo good as the ſtraw in the valleys, the cuſtom is to fodder their cows in racks, or cribs, in the open yard, which they think better than tying their cattle up to racks in houſes; for though in cold and rainy weather the houſes may keep their loins dry, yet in countries where the fodder is coarſe, eſpecially after wet and backward harveſts, when the ſpirit of the ſtraw is waſhed out by the rain, the giving cattle ſtraw from racks, from whence they cannot pick and chooſe, as from cribs they may, is judged to tend to the impoveriſhing the cattle, whereas in cribs they can pick the ſweet from the coarſe.

There is a very remarkable difference in cattle eating their fodder, when freſh threſhed, and when it has been threſhed two or three days, eſpecially if the ſtraw be but indifferent fodder. *Liſle's Huſbandry, vol.* I. *page* 392.

FOGGE, long graſs remaining in paſtures till winter.

FOISSEN, the natural juice or moiſture of the graſs or other herbs.

FOLD, the moveable incloſure wherein ſheep are confined during the night.

It appears that the ſheep-folds of the eaſtern nations were not ſuch as ours, but houſes erected for that purpoſe.

Mr. Garret, who has lived four years in Spain, ſays the ingenious Mr. Liſle, aſſures me, that in thoſe parts where he was, they fold their ſheep as we do ours, only their fold is made netwiſe with ſtrong cords, and about ſix feet high, with the bottom ſtaked down to the ground, and two cur-dogs, of a breed between a maſtiff and a greyhound, lie within the fold to guard the ſheep from the wolf.

"In favour rather of keeping a weather-flock than an ewe-flock on the hill country, beſides other conveniencies, you may have the benefit of the fold for barley at the principal time when it does moſt good, viz. on the fallows between the latter end of February and the middle of April, when the ewes cannot be folded.

"The limitation of an ewe-flock for folding and keeping on throughout the winter, or be it a weather-flock, ought to depend on theſe rules; Firſt, Not to keep more at winter than you can winter, either by meads, or ſowed graſſes and hay. Secondly, Not to be ſatisfied that you can provide hay for them by ſowed graſſes, as broad clover, &c. in caſe ſuch lands as are fitted to carry ſuch graſſes, lie at a diſtance for mowing, whereby you muſt maintain them with dung, where, by reaſon of carriage, it will be chargeable, unleſs your fold can maintain more ground than your out-lying lands to your farm, which, in the hill country, is not likely: and to carry but ſeven or eight pots of dung in a day, by reaſon of the diſtance, and mowing, is not reaping a profit, but bare exchanging: but if you have much land round about, and near your houſe, whereto you can carry thirty or forty load of dung a day, and which will bear broad clover hay, then you may increaſe your flock proportionably.

"As to fatting your ewes and lambs out of your flock, if you have lands diſpoſed for fatting, you ought to conſider, if you break your flock by drawing out ewes with their lambs for that purpoſe, what flock you will have left to fold on your wheat fallows, and how far your wheat land ſtands in need of a fold; for if you leave yourſelf not ſufficient, it will be indiſcretion to weaken your fold; beſides, it will hurt your breed; for you will draw off many forward lambs, which might, perhaps, have carried on the breed otherwiſe, and when a hill country farmer is ſettled in a flock, it is not good to be buying yearly, to keep up his complement, on account of many dangers which may from thence enſue: it is better, therefore, in ſuch caſe to buy ewes with their forward lambs to put into your fatting grounds; but in caſe you ſow wheat land good enough without the fold, or have another way of manuring it, by liming, &c. then it may be very well to fat off certain numbers of your flock.

"Though, ſays a very good farmer of my acquaintance, I have but a mean opinion of winter folding, or to fold on barley ſown, and may in time fallow on graſs-ground inſtead of barley-land, yet I would fold on barley-land fallowed or ſtirred, from the time my lambs were ſtiff enough after lambing to go on ſuch fallows; for, ſays he, the benefit of an acre ſo folded, is three times as good as one winter-folded for barley.

"Farmer Glyde, of the Iſle of Wight, with whom I was talking of huſbandry affairs, told me, there was one thing he believed I knew not of, which he would tell me; he would, he ſaid, adviſe me to fold my ewes and lambs on the barley-land in the ſpring, and divide my flocks in folding; for, ſaid he, two hundred ewes and their lambs will do as much, if not more good, by folding on an acre of land, as four hundred weathers: I have, ſaid he, folded a part of the ſame land at the ſame time two hundred ewes and their lambs, and in another fold of equal dimenſion five hundred weathers, and I have always found, that the folding of the ewes did me the beſt ſervice, and brought me the beſt corn.

"My ſhepherd is of opinion, that ewes ought not to be folded on the barley fallows, or any other fallows in lambing-time, but weathers only; for the lambs, being wet when lambed, would be dirtied with the fallows, and the ewes would preſently forſake them; therefore the ewes ought in lambing-time to be folded in the meadows, where it is clean, and the folds removed as often as the cold wind ſhould change from corner to corner. And afterwards, he ſaid, they ought to fold weathers on the barley till a fortnight after May, but the ewes never after Candlemaſs.

"It is plain, that the early folding an ewe-flock, and lambs in April, on wheat fallows, pinches the lambs, and ſo does folding them at that time on the barley grounds, both which are too cold for them, eſpecially on our hill country; care ought therefore to be taken, that thoſe lands do not of neceſſity want folding on in thoſe months, but that they may be otherwiſe provided for, and that during

that

that time the ewe-fold may be on graſs-grounds, or lay-grounds deſigned for fallows.

" We muſt be more cautious in April and May of folding an ewe-fold on the barley-land, they being wettiſh, than of folding them on the wheat ſown in Auguſt or September; becauſe the lambs in April and May make the ewes riſe often and move, whereby the ground becomes much more trodden at that time of the year by the ewe-fold, than it would be by a weather-fold, or an hog-fold, as may apparently be ſeen, if the folds be divided.

" Telling Mr. Gerriſh the grazier, and farmer Iſles, how dear Mr. Eyres our miniſter ſold fat lambs to the number of fifteen, May eighteenth, viz. for ten ſhillings and ſix-pence each, and that they had been folded all along to the very day he ſold them. They replied, that folding the lambs did very little hurt them with reſpect to their fat, provided they were drove pretty late to fold, and let out early in the morning.

" Walking with Mr. Raymond into his arable common fields, October twenty-fifth (anno 1708) we met his ſhepherd pitching the fold on the new ſowed wheat. I aſked him, whether he did not find that pitching the fold on the wheat at this time of the year, and a fortnight later, turned to a much better account than folding for the barley crop for the year following. Mr. Raymond and his ſhepherd readily replied, undoubtedly it turned to the beſt account to fold after this time on wheat. I ſaid, for my part, I had obſerved the fold carried on the land, deſigned for barley ſo early in the winter had little effect, its ſtrength being ſpent and waſhed away by ſpring, ſo that it will make but little ſhew in the crop of barley next ſummer, and that therefore I choſe to preſerve four, five, or ſix acres of wheat-fallow that lies warm, and will bear ſowing late, to carry my fold over to the latter end of October, rather than finiſh my wheat fold by the end of September, and then carry it on my barley; for though the latter part of October might, in our cold country, be too late to ſow wheat, yet it was better than to be ſo ſoon folding barley, which would be no better for it. To which they replied, I was much in the right. And as I have before obſerved how inſignificant the fold is in the winter, eſpecially in hard froſts. I imparted it to Mr. Raymond, who concurred with me, and ſaid, he had folded on arable land in ſnow, and found not the leaſt benefit: whereupon he reſolved in ſuch caſes to fold on meadow and paſture, in mighty expectations of graſs: but it made no return; wherefore in ſnows he now lets his ſheep ramble.

" Whereas I have ſaid, that in cold clay ground, and in a cold hill country, a winter-fold does little-good; yet I have by experience found the contrary in ſuch parts of the hill country, where the land is dry and light, and that it does great ſervice to the barley-crop. This difference may be reconciled thus, i. e. where the land, though called hill country land, does not lie very high, for the height much tends to the chilling of the ground. Again, the explanatory reaſon of this difference, though hardly accountable for, yet ſeems to me chiefly to lie in the chilling quality of the ground which at firſt receives the dung and piſs, and that deadens the ferment; whereas in warmer ground its progreſſion toward that end is ſupported by a ſufficient benign warmth, ſince in both ſorts of earth, the urine does undeniably ſink into the earth, and mix with it.

" My ground being cold and feeding, I ſhould in the ſpring of the year, when I come either to pitch my fold on the barley fallows, or on the ſown barley, ſet it very wide, in order to avoid the uſual inconveniencies of penning at that time, viz. the rankneſs and lodging of the barley, and the conſequences, thinneſs and coarſeneſs.

" It was the tenth of October (anno 1720) when my fold was going to be ſet on the wheat-fallows of a field, which was heavy land, and the fallows, where the fold was to go, were to be ploughed up the next day; I was afraid the land would be too wet to fold on after the wheat was ſown, and ſpoke to the ſhepherd about it. He ſaid, he believed I might be in the right, eſpecially ſince the rams had been ſome days put to ramming the ewes, becauſe the rams would keep moving and ſtirring the ewes all night in the fold, whereby the ground would be battered and trod, and ſo ſquatted, that the wheat might not get through.

" That the Greeks did pen up their ſheep, that they might piſs through hurdles, as in Herefordſhire, you may ſee in Palladius's calendar, November, to avoid dirtying and damaging their fleeces.

" Farmer Miles, whom I have often mentioned with approbation, adviſed me, if I would turn arable into meadow, and lay it up to graſs, to fling ſtraw upon it that is leſs than half rotten, and then fold upon it the ſame night, and it will bring the ground on very faſt.

" Purſuant to what has been before ſaid, that folding in winter for barley is not profitable, becauſe, by waiting for the fold's running over the land, we loſe the principal ſeaſon of fallowing; yet however it may be proper to fold till Chriſtmas, and then go on the wheat-lay; becauſe we can loſe no fallowing ſeaſon by that; we cannot well have finiſhed our fallowing any year before Chriſtmas.

" I find by Mr. Antill and Mr. Clerk, and others, that in Leiceſterſhire they have no winter-folding for barley; they leave off by Michaelmas at fartheſt, and ſometimes cannot fold again till May; the reaſon is, their lands are ſo wet they would be always in a poach, and the coldneſs of the lands would kill the ſheep: to help which defect, they muck their barley-lands, and from thence begin their huſbandry, and ſow wheat the year after, often under furrow, on their barley-ſtubble, for they ſay, if they ſhould dung their wheat-ground it would rot their wheat, and they ſow peaſe or beans after the wheat, and then lay the ground to ſummer-fallow again, to be mucked in May for barley, or to fold for wheat; ſo that they carry out their dung before it is half rotten, or the ſeeds of the weeds killed: but in their incloſures they ſow four crops of corn all on one earth, without dung, for the moſt part beginning with oats, and laying down to graſs with wheat.

" I am told, that in Dorſetſhire the aim of the farmers is, to fold on their ſheep-leaſes in the middle of July, and ſo till Michaelmas, that in the winter there may be a good head of graſs for the milch-ewes.

" It ſeems to be inconvenient to graſp at ſo large a wheat or barley-crop, as hardly to be able to compaſs it without folding late on the wheat after it is ſowed, or on the barley-land after it is ſowed; for by being under the above neceſſity, in order to compaſs what one has engroſſed, one may often be obliged to fold unſeaſonably on each ſort of corn, nor will the fold in that caſe make good the damage done to the flock by the lateneſs of the ſeaſon: and an ewe-fold is often damaged by folding on the cold land at the latter end of October; whereas it is better to come early with your fold off of the wheat-lands on to the barley

barley ley-gounds, and from the ſowed barley on to the wheat-fallows; for thereby you will fold the ſame quantity of ground of the reſpective grains without the reſpective inconveniencies.

"Between waſhing and ſhearing-time ſheep ought not to be folded, becauſe of dirtying their wool, nor from the cutting of the lambs till a fortnight after, nor in ſheap-leaſes or arable in wet weather, for it will tread the graſs into dung.

"A ſervant of mine, a man of very good underſtanding, tells me, he has been many years a ſhepherd, but could never obſerve that the fold ever did any good in froſty weather: particularly he remembers a very ſharp froſty winter, in which a whole flock uſed daily to gather to a hay-reek, in a ground where they were foddered, yet he could not obſerve there was any better corn there than elſewhere. I aſked him the reaſon of it; he ſaid, the froſt waſted and preyed on the dung; and I rather approve this obſervation of his, becauſe of the great prejudice ſtrong beer and ſpirits receive by being frozen, even ſo as to become mere *caput mortuums*.

"If froſt has the ſame effect on dung, by impoveriſhing it, that it is ſaid to have on the ſheep-fold, and on ſtrong beer: quere, whether it be proper or not, to leave horſe or cow-dung ſpread on land without ploughing it in?

"Mr. Raymond is alſo of opinion, that the winter-froſts do very much deaden the folding of the ſheep, and rob it of its virtue.

"Farmer Elton ſaid, the method he beſt approved of in folding, was always to fold that land firſt that was firſt deſigned to be ploughed, ſuch as white or whitiſh land, they not being apt to bear weeds, nor will the fold be apt to cauſe weeds to come, and ſuch land he would ſow firſt, viz. at St. James's-tide. I ſaid, I ſhould think, though ſuch land ſhould be ſowed ever ſo wet, yet, if the month of Auguſt ſhould prove dry and ſcorching, it would burn, and ſuffer by ſuch early ſowing. He replied, if ſowed wet, yet ſo as it came up, he never new the drought to hurt it.

"It was a very dry ſeaſon from the firſt of March to the ſixth of May (anno 1701) during which time I ſet my fold on my barley. Several of the farmers in my neighbourhood ſaid, it would be apt to do the barley more harm than good, for the ſheep would ſcratch up the ſeed; whereas, if rain had come, ſo that the ground had not been in a duſt, their ſcratching would have done no harm. But I rolled before I ſet my fold, and ſo I preſume the ground was ſo faſt as to receive the leſs damage, it being alſo ſtoney, and therefore the ſheep could not ſearch it ſo much as otherwiſe perhaps they might have done: the event was, the fold did no harm, but good.

"Mr. Gilbert of Maddington was telling me, the way of huſbandry about him, near Saliſbury, was, to fold on their wheat after it was ſowed till St. Luke's-tide, which is in the middle of October; then to draw off their flock for a month to fold their ſheep-leaſes, and then on the barley-fallows. I aſked ſome North-Wiltſhire farmers, if about them they ever folded on the wheat-land after it was ſowed; they ſaid no, they never knew it to be done in any parts thereabouts, yet folding after the corn was ſown did it more good than before; but the reaſon why they did not do it about Holt, &c. they believed was, becauſe they were forced to lay up the wheat-lands in high ridges by reaſon of the deepneſs of the earth, and its wetneſs, and the ſheep if folded on ſuch land, would do nothing but lie between the furrows, which would do the land but little ſervice: beſides, they ſaid, in the hill-country the land was rather of the lighteſt, and the treading of the ſheep, after it was ſowed, preſſed it cloſer than it was before, and ſo did it ſervice.

"Mr. Raymond aſſured me, that ſheep folded on ſandy lands would thereby be ſenſibly more inpoveriſhed than thoſe folded on clay lands, and this, ſaid he, the ſhepherds agree to, who live where there are ſuch different ſorts of land. The reaſon ſeems to be, becauſe the ſandy lands draw forth and drink up the moiſture of the ſheep, to fill up which emptineſs of the outward veſſels, a freſh juice muſt ſucceed, and ſo on; or elſe that the ſandy lands being hot, make the ſheep perſpire more than clay lands do, whereas the cold clay rather repels perſpiration.

"If ſandy or light ground, as has been before hinted, draws the fat and moiſture of the ſheep-fold off, ſo as to impoveriſh a flock more than if they had been folded on cold clay lands, it muſt be allowed, on the other hand, that light ground may be better enriched by a fold than heavy land, becauſe the light ground imbibes more of the moiſture and fat of the flock; and this gives ſome account why it is ſaid, poor lands often pay better for their folding than ſtrong lands: for the ſame reaſon winter folding, when the ground is wet and cold, holds no proportion to ſummer folding.

"Diſcourſing with farmer Biggs on huſbandry, he ſaid, he folded on the fallows all winter long, though never ſo wet; yet, ſaid he again, ſometimes the fold does harm: let it be never ſo wet, ſaid he, early in the year, folding on the fallows does no harm; for, in the firſt, there is heat enough in the ground at the firſt hand of the year to keep off the chill, and then the ground is not ſo ſettled, but that the rain ſoon runs through it, but at the latter end of the year the ground is ſettled; then treading it with the fold in wet weather makes it hold water, by which it may be chilled, and kneads the very wet into it, whereby there will be the leſs corn.

"Before I came from Crux-Eaſton in February (anno 1698) in order to go into the Iſle of Wight, I had a diſcourſe with an old experienced ſhepherd about folding the flock on fallows: he ſaid, as to wheat, it was excellently good, but they rarely folded on barley-land after it was ſowed, for if it was a whitiſh land, and a hot ſummer came, it would be burnt up: beſides, the ſheep would be ſcraping at that time of the year on barley-land, and would take the corn out of the ground; but the wheat, ſaid he, lays too deep for them to do ſo. But when I came into the Iſle of Wight, farmer Collins was of a different opinion, and ſaid, he had always folded with good ſucceſs on hot, dry, ſandy ground after it was ſown with barley, and was earneſt with me to try it; for, ſaid he, you will quickly ſee the benefit, and though the ſheep ſhould ſcrape, you will find the barley come thickeſt there. There is land, however, about Huſborne and Stoke in Hants, that will burn by folding on in the ſpring, and get more harm than good, if hot weather come, it being a hungry ſharp gravel.

"As it ſeems to me, the double folding on the early wheat-fallows, to be ſown on one earth, cannot occaſion the roots of the graſs ploughed-in to ſhoot up afreſh, but rather prevents it, by treading the earth down into a hard plaiſter, ſo that they cannot riſe; it is true, it may bring up afreſh new graſs, which, having weak roots, will eaſily be torn up by the draggs.

"Columella,

" Columella, ſpeaking of feeding ſheep, ſays, there is no ſort of land, or food, but what (by the continual uſe of that only) ſheep will be tired of, unleſs you give them ſome ſalt now and then to lick, from whence they may procure a new appetite to their meat and water. All the ſummer time during the hot ſeaſon they muſt be let out to feed as early as may be, while the dew is on the graſs; and when the ſun is about four hours high, they muſt be led to water and under the ſhade, and again to feed towards ſun-ſet. In the dog days the flock ſhould be ſo led as to feed with their heads towards the weſt in the forenoon, and towards the eaſt in the afternoon; for it is of great conſequence, ſays he, that the ſheep's heads ſhould be turned from the ſun, which would be hurtful to them. And Varro gives the ſame directions, becauſe, ſays he, the ſheeps heads are extremely ſoft. Perhaps this may be the chief reaſon of the rams and ewes in companies turning face to face, in hot ſun-ſhiny days. During the winter, and early in the ſpring, they ſhould be kept in their fold, till the ſun has melted the hoar-froſt from the graſs, which would occaſion rheums in their heads, and would alſo ſcour them: for this reaſon in cold wet ſeaſons of the year they ſhould be watered but once a day. They let their ewes, as Varro aſſures us, go out to feed with the reſt of the flock, but kept back the lambs, which were ſuckled by the ewes at their return, and then again ſeparated from them. They alſo tethered their lambs at ten days old, leſt they ſhould diſlocate or hurt their tender limbs by playing together." *Liſle's Huſbandry, vol.* II. *page* 178.

FOLE-FOOT, the ſame with colts-foot. *See* COLT'S-FOOT.

FOOD, a general name for whatever aliments are taken into the body to nouriſh it.

FOOD *of plants*, the particles they extract from the ſoil, air, &c. in order to their nouriſhment.

Philoſophical inquiries into the principles of vegetation, and the manner in which it is performed, are an object well worthy the attention of gentlemen whoſe ſituation allows them to purſue that truly uſeful and entertaining ſtudy. But as the induſtrious huſbandman, for whoſe benefit this work is chiefly intended, as a compendium of the beſt practice in agriculture, founded on the reſult of experience, cannot afford time for matters of ſpeculation; nor would they, in point of prudence, conſiſt with his neceſſary occupations, even if his education fitted him for ſuch reſearches; it may be ſufficient for him to form a general, but juſt, idea of the means by which plants are moſt ſucceſsfully raiſed. A proper notion of this will help to guide him in the management of his lands, and ſhew him in what ſtate the earth ſhould be, to enable the plants which he cultivates moſt eaſily and readily to find their neceſſary food. This general knowledge of the baſis of agriculture is even requiſite in every one who would be ſatisfied of the reaſonableneſs of his methods of proceeding.

Whether any one active principle does univerſally nouriſh all plants, or whether ſome particular ſalts or juices feed one plant, and others another, is a queſtion that has been warmly debated by philoſophers.

The ancients generally entitled the earth to the production of the animals, vegetables, and other bodies, upon and about it; but ſeveral of the moderns, and among them ſome of very great name, both here and abroad, have declared in favour of water, as the efficient cauſe of vegetation. Lord Bacon was of opinion, that, " for the nouriſhment of vegetables, water is almoſt all in all: and that the earth doth but keep the plant upright, and ſave it from over heat and over cold." Others carry this hypotheſis ſtill farther, aſſerting water to be the only principle or ingredient of all natural things. They ſuppoſe that, by I know not what proceſs of nature, water is tranſmuted into ſtones, into plants, and, in ſhort, all other ſubſtances whatever. Van Helmont, and his followers, to whoſe opinion even the illuſtrious Mr. Boyle has ſhewn a ſtrong propenſity, are very poſitive in this, and alledge, as proofs, the conſiderable growth of mint, and ſeveral other plants, in water, and his well-known experiment on a willow-tree. Van Helmont planted this tree, which weighed five pounds, in two hundred pounds of earth dried in an oven, and watered it with rain, or diſtilled water, after carefully covering the caſe in which it ſtood with a perforated tin cover, to prevent the admittance of any other earth. Five years after, weighing the tree, with all the leaves it had produced in that time, he found its weight amount to one hundred and ſixty-nine pounds three ounces; while the weight of the earth was only diminiſhed about two ounces.

Mr. Evelyn thought, with the learned Dr. Sharrock, whom he quotes, that water is, of its own conſtitution alone, a ſoil to vegetables, not only as the moſt genuine vehicle of the riches which it imparts to plants, through the ſeveral ſtrainers, and by means of which all change and melioration is effected; but becauſe it is, of all other ſubſtances, beſt diſpoſed for ingreſſion, to inſinuate into, and fertilize the earth; which is the reaſon why floated grounds are ſo remarkably fertile after the flood has ſubſided. " It is, ſays he, the neareſt of kin to the whole vegetable race; for to aſſert, with any confidence, what part of the mere earth paſſes into their compoſition; or whether the earth ſerves only for ſtability, or as a womb and receptacle to their ſeeds, I ſhall not undertake to diſcuſs; though I do not yet conceive the earth to be altogether ſo dull and inactive, as to afford no other aid to the generation of what ſhe bears; the diverſity of ſoils being infinitely various, and the difference of inviſible infuſions far beyond our arithmetic. But neither do I here by any means exclude the air, nor deny its perpetual commerce and benign influencies, charged as it comes with thoſe pregnant and ſubtile particles, which pervading and inſinuting into the earth's more ſteady and leſs volatile ſalts, that inteſtine fermentation is begun and promoted, which gives life, growth, and motion, to all that ſhe produces. Dr. Mayow has proved, that the moſt exhauſted and worn-out mould, if repaired by a bare expoſure to the air alone, without which it produces nothing. Nor can plants, totally excluded from the air, live, or ſo much as erect themſelves to any thriving purpoſe, as being deprived of that breath and vital balm, which no leſs contributes to their growth and nouriſhment than does the earth itſelf, with all our aſſiſtance. Beſides, we find that the air is near of kin and affinity to water, and indeed ſeems as it were but a thinner water; for how elſe are vines, and other trees of prodigious growth, maintained among barren rocks, and thirſty pumices where rains but ſeldom fall, if not from the benign influencies of the air?"

To this aerial food and moiſture it is that moſt of the ſedum kind owe their growth. Succulent groundſel, and the fragrant wall-flower, draw their nouriſhment from the ſame ſource. An aſh now growing out of a wall of the

abbey-church at St. Alban's, affords a remarkable inſtance how much even trees are nouriſhed by the air.

As all kinds of water, as well as air, contain many other ſubſtances beſides the pure elements of water and air, it is difficult to aſcertain whether theſe extraneous ſubſtances, or ſome of them, are not the food of plants. Dr. Woodward's experiments, as related in the Philoſophical Tranſactions, ſeem to confirm the opinion that they are: for he obſerves, that a great part of what he calls terreſtrial matter, mixed with the water in his experiments, aſcended up into the plant, as well as the water; and that the plants were more or leſs nouriſhed in proportion as the water in which they ſtood contained a greater or ſmaller quantity of that matter. With regard to Van Helmont's tree, and the growth of plants in water, he very juſtly obſerves, that nothing like what the advocates for water would infer from thence, can poſſibly be concluded from any ſuch experiments, unleſs the water uſed in them be abſolutely pure, homogeneous, and not charged with any ſort of terreſtrial mixture, to which the plant may owe its growth and increaſe: for that all water, even the cleareſt and moſt tranſparent, does abound with ſuch matter, will appear to any one who ſhall put ſome of the very pureſt into a clean glaſs phial, and ſtop it with the greateſt care. Though perfectly tranſparent at firſt, it will grow cloudy, if ſuffered to ſtand ſome time without being ſtirred, and at length depoſite an opaque ſediment. Filtring and diſtilling will indeed intercept ſome of the earthy particles with which it is naturally charged; but neither of theſe operations, nor any other that we know of, though ever ſo often repeated, will free it entirely from all extraneous matter, ſome of which will always remain in it, very fine and light, fit to attend every motion of the water, whoſe extreme tenuity, and exactly ſpherical globules, enable it to pervade ſmaller ducts than even imagination can conceive. We hardly know any fluid in all nature, except fire, whoſe conſtituent parts are ſo extremely ſubtile as thoſe of water. They will paſs through pores and interſtices, impervious to air, or any other fluid. This enables them to enter the fineſt tubes and veſſels of plants, and to introduce the nutritive matter lodged in the earth, conveying it to all parts of them; whilſt each, by means of organs it is endowed with for the purpoſe, intercepts and aſſumes into itſelf ſuch particles as are ſuitable to its own nature; letting the reſt paſs on through the common ducts.

The judicious Mr. Worlidge, uninfluenced by the new and prevailing mode of thinking in his time, according to which all vegetables were ſuppoſed to be fed by water only, declares poſitively, that he cannot but explode this opinion as deſtitute of foundation; for that, although ſeveral plants ſet in water only, do emit fibrous roots, and flouriſh therein for a time; yet, at beſt, this nouriſhment is but weak, becauſe water does not contain a ſufficient quantity of the true nutritive particles, as the willow, poplar, and other aquatic plants raiſed therein, demonſtrate, and as is ſtill farther evident from their better thriving if the water be often changed. "Experiments, ſays he, have been made of gourds and cucumbers, planted in baked earth, and watered with water only; and after they have grown to ſuch a bulk as the experimenter thinks proper, they are weighed, and alſo the earth, which laſt is probably but little diminiſhed, or perhaps not at all; from whence they conclude, that the ſubſtance of thoſe vegetables proceeded from the water. Thus have men made experiments ſpeak as they would have them, to favour the new opinions they would impoſe on the credulous."

Spring and rain-water contain pretty near an equal charge of vegetable matter; river water more than either of them. Nor can any doubt be made, but that the water which falls in rain at ſometimes, is more charged with particles fit for the vegetation of plants, than that which falls at others. A more powerful degree of heat muſt draw up a larger quantity of that matter, with the humid vapours which form rain, than a more feeble warmth poſſibly can. The water of one ſpring may alſo flow with a higher charge of this matter than that of another: this depending partly upon the quickneſs of the ebullition of the water, and partly upon the quantity of that matter latent in the earth, through which the fluid paſſes, and the greater or leſs laxity of that earth. For the ſame reaſon, the water of one river may abound with it more than that of another; and the ſame river, when much agitated, may bear up more of it than when it moves with leſs rapidity.

Though water be not itſelf the food of plants, it is an abſolutely neceſſary agent, by which the matter proper for their nouriſhment, which remains inactive till it be diluted by, and incorporated with this fluid, is conveyed to them, and introduced and diſtributed into their ſeveral parts, both from the earth and the air. But ſtill it is not capable of performing even this office, without the concurrent aſſiſtance of heat, which gives it the neceſſary action, exalts and digeſts the nutritive juices, dilates the pores of the plant, and raiſes the ſap into the ſtem, branches, and fruit, where the ſun perfects the work, by ripening it.

The neceſſity of heat in vegetation is apparent from our fields and foreſts, our gardens and our orchards. We ſee, that in autumn, as the power of the ſun decreaſes, ſo its effects on plants diminiſh, and their vegetation ſlackens by degrees. Its failure is firſt diſcernible in trees, which, being raiſed high above the earth, require the moſt heat to elevate the water, charged with their nouriſhment, to their tops and extremities; ſo that for want of freſh ſupport and nutriment, they ſhed their leaves, unleſs ſecured by a very firm and hardy conſtitution, like that of our ever-greens. Next, the ſhrubs part with theirs; and then the herbs and lower tribes; the heat being, at length, not ſufficient to ſupply even theſe, though ſo near the earth, the fund of their nouriſhment. As the heat returns with the enſuing ſpring, they all recruit again, and are furniſhed with freſh ſupplies of verdure: Firſt, Thoſe which are loweſt and neareſt the earth, becauſe they require the leaſt degree of heat to raiſe into them the water with its nutritive charge; next, the ſhrubs and higher vegetables, in their turns; and, laſtly, the trees. As the heat increaſes, it grows too powerful, and hurries the ſap with too great rapidity through the finer and more tender plants. Theſe, therefore, go off and decay; and others, which are more hardy and vigorous, and require a greater degree of warmth, ſucceed in their order.

Mr. Tull is the only perſon who makes earth the food of plants. The experience of all ages contradicts this opinion; for the neceſſity of inducing ſomething into poor ſoils, to enable them to produce crops, is univerſally acknowledged; whereas, if earth alone was the food of plants, it would in all caſes produce the ſame effect.

As to the grand queſtion, whether plants of different kinds are nouriſhed by one univerſal food, or whether each particular

particular ſpecies imbibes only its peculiar aliment; the ſupporters of this laſt opinion, among whom are the great lord Verulam and Dr. Woodward, ſay, it is not poſſible to conceive that one uniform homogeneous matter ſhould conſtitute bodies ſo unlike in all reſpects as the various tribes of vegetables; nay, even as the different parts of the ſame plant. But a moment's reflection will ſhew, that the latter part of this objection confutes the former; for if the plant has the power of altering the original juices taken in by the roots into ſo many various forms as experience proves it has, each plant may be indued with the faculty of aſſimilating to itſelf the juices it meets with in the earth; as we find the ſame food not only nouriſh different animals, but produce in each its peculiar character.

We have ocular demonſtration, that the willow and alder thrive beſt on a moiſt ſoil, and that the elm, pine, fir, and cypreſs, prefer a drier earth. Yet theſe, and many more of the wideſt difference, are ſometimes ſeen to draw their whole ſuſtenance, bulk, and ornaments, whether annual or perennial, from the juices they find in the ſame piece of ground, and from the ambient air and dews; though our ſtricteſt diligence cannot diſtinguiſh the particular aliments which approach their ſeveral roots. Changing the earth about the roots of theſe, or any other trees, whoſe bark, ſap, fruit, and ſeed, are of very different kinds and qualities, will only make each tree proſper the better. "Hence, ſays Dr. Beal, we may juſtly ſuſpect, that the very contextures of their bodies, from the firſt ſpirting of their ſeed, and as they are formed gradually from the inviſible principles or ſpirit and vigour of their ſeeds, however ſmall and imperceptible, are the natural alembics, where the common rain-water and air are digeſted into very much differing leaves, fruit, ſeed, reſins, gums, &c. perhaps as the cow's belly converts the common juices of all ſorts of graſs into milk, or as the bee collects honey and wax from all ſorts of flowers."

The ſame ſoil that has once been proper for the production of ſome ſorts of vegetables (continue thoſe who think that each particular ſpecies of plants has its particular food) does not always cortinue to be ſo; but in time loſes its property. If wheat, for example, be ſown upon land proper for that grain, the firſt crop will ſucceed very well, and perhaps the ſecond, or as long as the ground is in heart; but in a few years it will produce no more, if ſown with that corn. Some other it may, as barley, rye, or buck-wheat.

That this is owing to an improper culture of the land, more than to any defect in the ſoil itſelf, will evidently appear to thoſe who ſhall candidly weigh the principles of the New Huſbandry, when that ſubject comes to be treated of.

Mr. Du Hamel makes no doubt, but that the particles which plants appropriate to themſelves, take different forms in each plant, and even in the ſeveral parts of the ſame plant; but, as he juſtly obſerves, it does not at all follow from thence, that they were not originally the ſame. What would induce one to think them the ſame, is, that plants of different kinds rob one another of the nouriſhment which is in the earth: for, if a lettice, for example, drew from the earth a food different from that of endive, a lettice planted among endive would not only thrive better than if planted among other lettice, but as well as if no other plant was near it. But we know, by experience, that this lettice would grow very poorly, and conſequently that plants, though of different ſpecies, do hurt and rob one another. If each plant drew from the earth only the particular juices proper for itſelf, poppies, thiſtles, &c. which kill wheat, would not in that caſe do it any hurt, farther than by ſhading it with their ſtalks. But that the injury they do the corn is chiefly occaſioned by their roots, which conſume the neceſſary nutritive juices, is evident from this, that if dry branches were ſet in ſuch numbers as to make even a greater ſhade than thoſe weeds, they would not equally prejudice the growth of the wheat.

After ſome other arguments of equal force, Mr. Du Hamel concludes, that plants of different ſpecies feed on the ſame, or nearly the ſame ſubſtance; that there is no plant which does not rob thoſe that are within its reach of ſome part of their food; and that the ſoil which once is good for any one kind of plant, will always be able to ſupply it with food, provided it be properly cultivated.

To prove that the ſame juice takes different qualities in the veſſels of the ſame plant, he inſtances an experiment which he made, by grafting a young lemon, of the ſize of a pea, by the ſtalk, upon a branch of an orange tree. It grew there, ripened, and retained its quality of lemon, without partaking in any ſhape of that of the orange. The juices of the orange tree muſt therefore have changed their nature at once, on their paſſing into the lemon.

It is an old opinion, generally received by the ancients under the name of occult qualities, or ſympathy and antipathy, that ſome plants delight in being near each other, while others will not live together. Several of the moderns have likewiſe embraced this ſentiment, and urged in ſupport of it, the fig-tree and rhue, garlick and the roſe, which, ſay they, agree remarkably well together, becauſe the juices ſuited to the one are avoided by the other. Lavender, laurel, thyme, marjoram, and other aromatic plants, cannot, on the contrary, according to them, flouriſh together, becauſe they feed on ſimilar juices, of which they rob one another. Mr. Evelyn ſeems to be nearer the truth, when, ſpeaking of this ſubject, he aſſigns as a reaſon why ſome plants will not thrive near others, certain effluvia or ſteams emitted by the one, which may be noxious to the other. Plants will not thrive under the walnut-tree, the oak, and others of the ſame kind, becauſe their numerous and wide-extended roots exhauſt the earth around them, and the drippings from their leaves are impregnated with an acrid matter, which is an enemy to vegetation.

Though there are evident inſtances of an election of food in ſome plants of very different kinds, ſuch as the aquatic race, and thoſe which delight in a dry ſituation; yet, ſo far as relates to the farmer, they may be ſaid to be nouriſhed with one and the ſame ſubſtance; but at the ſame time it is neceſſary, that both the earth and that ſubſtance be fitted for receiving and nouriſhing them: for be the earth ever ſo good, rich, and proper for the production of vegetables, little will come of it, unleſs its parts have that juſt degree of ſtrength, or coheſion, which ſhall give ſtability to the plant, and at the ſame time afford an eaſy admittance to the fibres of its roots, to ſpread and extend themſelves in ſearch of that food.

FOOT, the part that ſupports an animal.

A horſe may have a very well made foot, and well proportioned, and yet if it chance to be thin and weak, the buyer will be diſappointed of his expectation; for ſuch a foot is liable to be ſpoiled in ſhoeing, by travelling on hard ſtony grounds, by too much drought in hot ſeaſons, or

by too much moiſture in winter. A thin foot is that where the cruſt or horn is thin. This may be eaſily ſeen when the ſhoe is taken off, becauſe the verge all round the ſole will appear thin; and where it is ſo, a horſe will winch with the leaſt touch of the pincers; but as this trial will ſeldom be allowed by buying of a horſe, the beſt way to thoſe who would be acquainted with ſuch things, is to obſerve the bottom of the cruſt, which is generally ragged, and where the ſhoe-nails are clenched and rivetted: if theſe be high, it is a token the foot is thin, and that there has not been ſufficient hold for the nails, without driving them a good way upwards in the cruſt. In a thin foot, the heel and frog are alſo apt to be ſoft and tender to the touch, and by reaſon of the weakneſs natural to ſuch kind of foot, it ſometimes turns away, and one point of the heel will ſtand higher than the other, though this may be alſo owing to the crookedneſs of the paſtern joints, and will ſometimes happen where the foot is tolerably ſtrong; but is moſt common to ſuch as have weak feet; and where it is ſo, the horſe wears his ſhoes more on one ſide than the other, and often cauſes him to cut, and go lame in a journey.

As a thin weak foot is juſtly reckoned a very great defect in a horſe, ſo a very ſtrong foot is not always the moſt eligible, but is liable to ſeveral accidents. A ſtrong foot has the fibres of the hoof very diſtinct, and for the moſt part run in a ſtraight line from the coronet to the toe, like the grain of oak, lignum vitæ, or any other hard wood that eaſily ſplits; and though ſome ſuch feet will laſt very well, and keep free from accidents, where ſufficient care is taken to keep them moiſt and pliable; yet when they happen to be neglected upon a long journey, or much hard riding, eſpecially on dry ſtony grounds, or when they ſtand long in a hot dry ſtable, they will go lame and tender, at the ſame time that no defect is to be ſeen on the foot; for when the ſoft parts within are bruiſed by the hardneſs of the hoof, or by the thickneſs and hardneſs of the ſole, which in all ſuch feet is like a plate of iron; and when this happens, a horſe will be in pain, and the true cauſe ſometimes not found out for a long time, which I have known in ſeveral inſtances; nor is it eaſy to reſtore ſuch feet to a due temperament.

When a horſe that has a very ſtrong foot takes up a channel nail, or happens to be cut into the quick with a ſharp bone, a ſharp flint, or piece of glaſs, and a flow of humours follows upon ſuch a wound or puncture, the confinement theſe meet with from the ſtrength of the foot create much anguiſh, and for want of vent below, frequently cauſes an eruption round the coronet, which proves for the moſt part troubleſome, and makes the cure tedious and uncertain, eſpecially when ſuch caſes happen to fall into bad hands.

I have known ſome inſtances where the hoof and the ſole have been quite looſened from all their attachments to the foot, the filaments and fibres that unite the horny part to the fleſh being all torn and pulled aſunder by the thickneſs and ſtrength of the horn; and where this happens in any degree, it is apt to leave a tenderneſs behind it, unleſs an uncommon care be taken to prevent it.

But the greateſt inconveniency in a very hard ſtrong foot, is its being ſubject to refts and fiſſures, which cleave the hoof quite through, ſometimes from the coronet down to the bottom; and this kind of foot is the more eaſily expoſed to ſuch accidents, that the horny fibries have a more viſible ſtraight direction than where the feet is more ſoft and pliable; theſe clefts being for the moſt part in the quarter, ſeldom admit of any other remedy than extirpating the whole piece that lies next the heel, which defect is from thence called a falſe quarter, wherein the cure is ſeldom ſo perfect, eſpecially in the fore feet, as to leave no infirmity or blemiſh behind it. When the fiſſure or cleft does not penetrate through the horn, but makes a line on the ſurface, it is called a ſand crack, being very common in ſome ſandy countries, where the horſe's hooſs turn dry and crack with the heat of the ſand. Theſe are but little regarded where the lines are ſuperficial, and not deep in the horn, and are often cured by raſping the foot, and keeping it cool and moiſt. However, it is a defect that muſt leſſen the value of a horſe, in proportion to the degree of goodneſs or badneſs of his foot; for when the foot happens to be otherwiſe bad, theſe blemiſhes often degenerate, and are of ill conſequence.

The next defect I ſhall take notice of in the feet, is of thoſe horſes that have narrow heels. Some horſes feet are tolerably good, even where the heels are narrow; but when the foot is hot and inclined to rottenneſs, and the quarters loſe the round turn that they ought to have as they approach the heel, and look as if they were bent and pinched together, inſomuch that the heels of ſome ſuch horſes are not above two fingers in breadth, then the foot is bad; and the way that many take to mend theſe kind of feet, by hollowing on each ſide the frog, and thinning the quarters to cauſe them to ſtretch to a wider ſhoe makes them worſe; for the ſtretching out the quarters contracts the hoof on the inſtep, and almoſt always turns ſuch horſes hoof-bound, and wire heeled.

But horſes often grow hoof-bound from other cauſes, and in ſome it proceeds from the ſhape of the coffin-bone, when it happens to be flat or hollow, where it ought to be riſing and round, when the coffin drops by thinning the ſole too much, and not taking care to ſtay it up with ſtuffing and ſplinters, and from diſeaſes in the feet that leave a weakneſs and deformity in them. But when a horſe that has a very ſtrong flinty foot happens to be hoof-bound, the caſe generally turns out bad. For the harder the hoof, the more it preſſes round the inſtep and heel. This preſſure makes the parts all round the coronet to grow fleſhy and project over the inſtep, ſo as to be conſtantly bruiſed by the upper part of the hoof, eſpecially when a horſe carries any great weight upon him, and by this means in the end ingenders a quitter, which creeps ſo under the hoof that it can ſeldom be removed without the loſs of a quarter, the ſame as when there is a fiſſure and cleft, or rather worſe, becauſe of the depreſſion and binding all round the upper part of the foot with the diſtemperature of the coronet, which often renders ſuch cures both very tedious and imperfect. Therefore this ought to be well looked into, eſpecially in chooſing a ſaddle horſe, that his feet be tolerably ſhaped, ſmooth, and cool, not narrow heeled, nor hoof-bound, neither weak-footed, nor too remarkably ſtrong; for moſt horſes of this latter kind are alſo coarſe, and chiefly fit for labour.

Another thing that ought carefully to be looked into, is that both his fore-feet be of equal ſize; for wherever this defect is the leaſt apparent, though it may proceed from a horſe's uſing one leg more than the other, as it happens to working men who uſe the right-hand and arm more than the left; yet when one foot is ſmaller than the other, it is a blemiſh, and carries ſome doubt that ſuch a foot may in time fail and periſh, even as theſe do that have

been

been hurt by accidents, or after old lamenesſes in the ſhoulders, legs, and muſcular parts, where the ſoot at laſt periſhes in proportion as the muſcular and nervous parts ſhrink and diminiſh.

Another defect in horſes feet, is when they are flat and without depth. If ſuch a ſoot happens to be ſtrong, and the hoof ſmooth; if the ſole be alſo firm, and the frog no ways rotten or fleſhy, ſuch a horſe will endure the roads tolerably well. But when a flat ſoot is ſhaped like an oyſter, has many rings and wrinkles, if the ſole be ſoft, and the frog fleſhy and ſpongy, it is a very great defect. Some horſes are ſo remarkably faulty in this reſpect, that the frog bunches out beyond the bottom cruſt of the hoof, that their ſhoes muſt be made hollow, and the plates ſo broad as almoſt to cover the whole bottoms of their feet, to keep them from the ground. But indeed ſuch horſes are only fit for draught, and not for the ſaddle.

Some horſes have tolerable good feet, only that their heels are low. Horſes that have long yielding paſterns are the moſt ſubject to this defect, and alſo thoſe that have their paſterns very ſmall, ſhort, and ſtanding almoſt quite upright; theſe have generally long heels and flat feet, and their fore-legs coming ſtraight down from the ſhoulder to the foot, without any bending of the paſterns, and for this reaſon are frequently called goat-legged. Many of the horſes bred in the fens are of this kind, have but an aukward uſe of their limbs, and make very bad travellers, and thoſe low heeled horſes which have very long yielding paſterns, are apt to have their heels wear quite to nothing upon a journey, and all the care imaginable in ſhoeing cannot prevent it.

A very high heel is another extreme, which greatly leſſens the value of a horſe; for even where ſuch a foot happens to be ſtrong and ſmooth, it is nevertheleſs the cauſe of unſteadineſs in a horſe's going, expoſes him often to trip and ſtumble, to ſprains in the coffin and paſtern-joints, &c.

There is one kind of horſe, eſpecially among the coach and cart breed, very remarkable for a large deep ſoot; the horn extremely thick and ſcaly, the heels broad and mouldering, and are apt to grow ſo very faſt, that the farriers when they go about to ſhoe ſuch horſes, thinking to eaſe them of their great load, and to bring their feet into a better ſize, pare and raſp them to ſuch a degree, that they leave their feet much larger about the coronet and inſtep than at the bottom; ſo that they always look as if they went upon pattens, which is not only very ugly, but ſuch horſes are ſeldom good for much.

A very large ſoot of any kind is to be avoided in a horſe, even ſuppoſing it to be in itſelf firm and good. But when I ſpeak of a large foot, I mean only when it is diſproportioned to his other parts, for a large horſe muſt of courſe have a larger foot than a ſmall one. But when we ſee the foot large, and the limb ſmall, in all ſuch it muſt be obſerved by thoſe who have experience, that the bones and ſinews are alſo ſlender, which not only denotes weakneſs, but heavineſs and inaptitude to any briſk and vigorous action; and therefore unfit for the coach or ſaddle, but to draw in a cart or waggon, or to carry a burden.

Some object greatly againſt white feet, as being generally worſe than thoſe of any other colour. Indeed when a horſe has too many of his feet white, they do not always prove the beſt, yet I have ſeen white-footed horſes have their feet ſuch as the ableſt judges could not find fault with. When a foot is ſmooth and tough, of a middle ſize, without wrinkles, neither too hard and brittle, nor too ſoft, and when the heel is firm, open, and no ways ſpongy or rotten, and the frog horny and dry, and the ſole ſomewhat hollow, like the inſide of a diſh or bowl, whatever be the colour, ſuch a foot will for the moſt part turn out good, though the dark or black hoof, where it reſembles that of deer, is generally the beſt; and for this reaſon thoſe who are the moſt curious about a horſe's feet, do not chooſe ſuch as have much white upon their legs and paſterns, to avoid their having too many white feet. *Gibſon's Farriery, vol.* I. *page* 19.

FORK, an inſtrument divided at the end into two or more points, or prongs.

FORKEN ROBIN, an earwig; ſo called from its forked tail.

FOSSE, a ditch or moat.

FOSTAL, a way leading from the main road to a large houſe.

FOUL FEEDING, a voracious appetite to which ſome horſes are ſubject, and though not properly a diſeaſe, is often the cauſe of various maladies. It is generally the effect of ſome latent diſtemper, as vermin, which have a quite different effect on ſome horſes to what they have on others; for as horſes of a lax habit of body often loſe their appetites by worms, and are frequently griped and ſickly in their bowels; ſo horſes of ſtrong rigid conſtitutions, that can bear the irritation thoſe animals make in their inteſtines, are often voracious in their appetites, and continually craving after food.

Foul-feeders, however, differ in ſome things from thoſe that have voracious appetites: for as the latter crave only after their common food, and can hardly ever be ſatisfied; ſo the latter will leave their hay to eat their litter, and ſeem to like it the better when it is well ſauced with their own dung and urine; and, therefore, they may be properly ſaid to have a vitiated or depraved appetite. Though this does not always proceed from a voracious appetite, yet the firſt is often productive of the latter, and may probably be occaſioned by enlarging the capacity of the ſtomach and inteſtines to ſuch a degree, that nothing will ſatisfy their cravings, but what has weight and ſolidity; for the ſame kind of horſes will eat mould and wet clay, or any kind of foul naſty weeds out of the ditches, and in the ſtable will eat ſtinking muſty hay, which the generality of horſes will refuſe.

There are others of depraved appetites, that are neither foul nor voracious feeders, ſuch as we often obſerve eat dry loam or mud out of the walls, which perhaps denotes ſome vitiated juices in their ſtomach; and this alſo is frequently owing to vermin, or at leaſt to a bad digeſtion, though perhaps not to any imbecility in their conſtitutions; for though thoſe horſes have a longing after thoſe extraneous things, yet their appetites at the ſame time ſeldom fail: but as this is often owing to full feeding, with the want of ſufficient exerciſe, ſo we often ſee them recover and quite loſe that vitiated taſte, when they come to ride a journey, or go upon any other conſtant exerciſe.

The beſt method in all theſe caſes of a vitiated or depraved appetite, is to begin with purging, and to diſſolve chalk in their water, and afterwards to give them good exerciſe. The ſame method may be complied with to thoſe that feed voraciouſly. To theſe the following draught may alſo be given, to blunt their appetites:

Take

Take a large handful of the roots of marſhmallows, cummin-ſeeds, and fenugreek-ſeeds, of each an ounce: liquorice roots ſliced, half an ounce; boil in three pints of water till the roots are ſoft and ſlimy, then pour off the decoction, and diſſolve in it an ounce of gum-arabic, and add four ounces of linſeed-oil.

Let the horſe have four handfuls of this every morning faſting, till his appetite abates. If the horſe be lean, which many voracious feeders are, he will gather more fleſh under this management, and as his fleſh increaſes his appetite will abate.

As to foul feeders, many of theſe begin with voraciouſneſs, and when they come to be ſtinted, take to eating of their litter to fill their ſtomachs, and in time take a great liking to it; and it is obſervable, that many of the horſes that go broken winded, have this evil faculty; and therefore I ſhould adviſe any one who has a foul-feeding horſe, to keep his ſtall as clean as poſſible, to let no wet, dirty litter, lie under him, nor to put his litter under the manger, but to beſtow it on ſome other horſe, otherwiſe they will paw it out, and feed upon it greedily; but clean ſtraw that has not been ſoaked with horſe-piſs and filth, will never hurt any horſe; for though there is no harm in the urine, yet when the ſtraw has been ſoaked in it with the dung, it often turns into a wad, or like a ſponge in their bowels, and cauſes great diſorders. But when their wet litter is taken away every morning, it may be the means to make them leave off that ill habit. *Gibſon's Farriery, vol.* II. *page* 96.

FOWL, a general name for all ſorts of birds; but uſed in a particular ſenſe to ſignify ſuch as are bred in the farmer's yard for profit.

The countryman's farm or habitation cannot be ſaid to be completely ſtored or ſtocked without fowl as well as beaſt, which yield a conſiderable advantage by their eggs, brood, bodies, and feathers. Any poor cottager that lives by the highway-ſide may keep them, they being able to ſhift for themſelves the greateſt part of the year, by their feeding on inſects, corn, or any thing almoſt that is eatable by any other ſort of animal: and therefore they are kept to great advantage at barn-doors, and other places, where corn or ſtraw is ſcattered.

As for cocks and hens, we ſhall not enter into a deſcription of the ſeveral ſorts of them, only obſerve that thoſe that are the beſt breeders, and the beſt layers, are to be choſen, the oldeſt being always the beſt ſitters, and the youngeſt the beſt layers; but no ſort will be good for either, if they are kept too fat. The beſt age to ſet a hen for chickens, is from two years old to five; and the beſt month to ſet them in, is February, though any month between that and Michaelmas is good. A hen ſits twenty days; whereas geeſe, ducks, and turkeys, ſit thirty. Obſerve to let them have conſtantly meat and drink near them while they ſit, that they may not ſtraggle from their eggs, and chill them. One cock will ſerve ten hens.

If fowls are fed with buck or French wheat, or with hemp, canary, or millet-ſeed, which is commonly ſown in March, it is ſaid they will lay more eggs than ordinary; and buck-wheat, either whole or ground, and made into paſte, which is the beſt way, is a grain that will fat fowls or hogs very ſpeedily; but the common food to fat them with is barley-meal wet with milk or water; but wheat-flour is better: but if you deſign to bring up chickens, give a barley-corn or two to each of them, as you take them out of the neſt, and ſo continue to feed them till they are fit for fatting.

For the beſt methods of breeding ducks, geeſe, turkeys, pigeons, ſwans, peacocks, &c. *ſee each under its proper article* DUCKS, GEESE, TURKEYS, &c.

FOWL's *Dung. See the article* DUNG.

FOX, a well known animal of the canine kind, with ſharp ears, and a buſhy tail.

The fox is very prejudicial to the huſbandman, by taking away, and deſtroying of his lambs, poultry, geeſe, &c. eſpecially in places that are near foreſt-woods, and covert places. The beſt way of deſtroying them is with guns or traps, after this manner: if you deſign to ſhoot them, procure a ſheep's paunch, and tying of it to a long ſtick, rub your ſhoes well upon it, that the fox may have no ſcent of your feet, and draw the paunch after you, with which make a trail a mile or two in length; and order it ſo as to bring it near ſome thick-headed tree. At which place, when you have made your trail, leave your paunch, and with your gun get up into the tree; and as ſoon as it begins to be dark, you will ſee him come by you upon the ſcent of the trail, where you may ſhoot him. Obſerve that you draw the trail to windward of the tree, if you can.

But if you have a mind to catch them with a ſteel-trap, which is the ſureſt way, chooſe a place to ſet it in a plain part of a large field; let it be out of the way of all paths, but not near either a hedge or any ſhelter. Open your trap, and lay it upon the ground, and cut out in the turf juſt the form thereof, and take out ſo much earth as may make room to lay it, covering of it again very neatly with the turf you cut out; and becauſe the joints of the turf will not cloſe exactly, get ſome of the fine mould that is to be found in a new caſt up mole-hill, and fill the joints with it, taking ſome graſs, and ſticking of it in the mould, as if it grew there. Make all ſo fine and plain, as that it may deceive your own eye to look upon it. About eight or ten yards from the trap, three ſeveral ways, ſcatter ſome of the fine mould that you had out of the mole-hill, very thin, upon a place about fourteen or fifteen inches ſquare; and upon theſe places, and where the trap is, lay two or three ſmall bits of cheeſe, and with a ſheep's paunch, as is before directed, draw a trail of about a mile long to each of the three places, that are at a diſtance from the trap, and from thence to the trap, that ſo the fox may come upon one of thoſe places firſt, which will make him approach the trap with more boldneſs, where you will ſeldom fail of him; only you muſt obſerve not to faſten your trap, but to leave it looſe, that he may draw it to the hedge-ſide, or to ſome cover, or elſe he will bite off his leg, and be gone.

Some bend down a ſtick in the wood, and ſet a trap for them in their paths, like that which is ſet for woodcocks, which hangs them up, or any other ſort of vermin. *Mortimer's Huſbandry, vol.* I. *page* 312.

FOX-TAIL GRASS, the ſame with cow-wheat. *See the article* COW-WHEAT.

FRAGRANT, odorous, ſweet of ſmell.

FREE-MARTIN, a barren heifer.

FRENCH BARLEY, a ſpecies of barley called by botaniſts *tritico ſpeltum*. Some call it wheat-barley. It is naked, and the grain like wheat, but the ear ſhaped like that

that of the common barley. This ſpecies is often ſown about Rowley, Hamſtal, and Redmore, in Staffordſhire. It yields a large increaſe, and makes good bread and good malt." *See the article* BARLEY.

FRENCH BEANS, *See the article* BEANS.

FRITH, an arm of the ſea running into the land.

FROST, the laſt effect of cold; the power or act of congelation.

Froſt is a great fertilizer of land, and therefore when the ſoil be a harſh, churliſh, or obſtinate clay, it ſhould be turned up in ridges at the beginning of winter, which will greatly tend to remove its bad qualities, and ſeparate its particles.

Hard winters are generally of ſervice to corn in many reſpects; eſpecially if the land has been thoroughly drained, and is well covered with ſnow. This laſt mellows the ground, and keeps it warm; while froſt, neither the rigour nor duration of which need be feared if it comes on gradually, and the land is dry, not only kills great numbers of vermin and inſects, but, by leaving the earth in a looſe ſtate, fits it for roots to extend themſelves therein as the warmth of the ſpring approaches, and thereby enables them to produce ſtrong plants; whereas frequent rains in winter, without froſt, ſodden the earth, which afterwards produces nothing but blades, ſoon to be deſtroyed by the hoar froſts of the ſpring, by inſects, and by weeds; or which would yield at moſt only ſtraw without grain. The winter's froſts may indeed nip off the blades; but then the roots being unhurt, new ones will ſhoot up in the ſpring. This was the caſe in the remarkably ſevere winter of 1608, of which Mezeray ſpeaks, and which, notwithſtanding its extreme ſeverity, was followed by a plentiful harveſt; and ſuch alſo, or nearly ſuch, was the long winter of 1729.

The great danger from froſts is, when the earth is wet, and not covered with ſnow. For example, if a ſtrong froſt returns after a ſudden thaw, the fibres of the roots are broken by the expanſion of the ſurrounding water when frozen, and the too great abundance of moiſture in the plants themſelves, when frozen, tears their fibres to pieces by the ſame expanſion. This was what happened in 1684.

Early in the ſpring of 1710, the parliament of Paris, hoping that the corn cut off by the preceding winter would ſhoot out again, as it did after the winter of 1608, mentioned by Mezeray, forbid ſowing anew the lands which had been ſown the autumn before: but the expectation now proved groundleſs, the plants having been totally deſtroyed by repeated froſts, intermixed with frequent thaws; ſo that had it not been for the barley that was ſowed afterwards, which yielded ſuch prodigious crops, that the French ſtill call that year the year of barley, the dearth muſt have been much more dreadful than it was. In that very ſpring, after the hard winter, ſeveral people in the dutchy of Berry, and elſewhere, ſowed wheat, which ſprouted well, and grew, but did not ſpindle; whereupon ſome mowed their crops, and others turned in cattle to feed as in a meadow; but after another winter had paſſed over them, theſe very fields yielded the next year as plentifully, as if they had been ſown anew. In incloſed grounds, the corn near hedges, which ſecured it from the north wind, reſiſted all the rigour of that exceſſive cold; and in other places, where the poor peaſants raked up all the ſnow they could collect, and ſpread it with their hands upon the uncovered ſpots of their ſmall fields, their corn was preſerved, and yielded a good crop.

A gentleman, now living in England, had a field of wheat ſo greatly damaged by alternate froſt and thaw, that the neighbouring farmers thought he could not do better than plough it up for ſpring corn; but obſerving that many of the plants were yet alive, and in a condition to be recovered, though thinly ſcattered, he hand-hoed the whole, and reaped three quarters of corn from each acre of this land.

FROWAR, the name of an edge tool, uſed in cleaving laths.

FRUNDELE, two pecks, or half a buſhel.

FRUSHES. *See* RUNNING-THRUSH.

FUDDER, a load. It properly relates to lead, and ſignifies a certain weight, viz. eight pigs, or ſixteen hundred weight.

FULLERS EARTH, a native earth found in many parts of England, and much uſed by fullers in cleaning and ſcouring their cloth. It is of a very fat nature, and very full of that vegetative ſalt that helps the growth of plants; and therefore may be uſed with advantage, where it is found in plenty, on ſome ſorts of land.

FURLONG, the eighth part of a mile.

FURROW, a trench made by the plough.

FURZE, *whins* or *gorſe*, to which C. Baukin and Mr. Ray, give the name of *geniſta ſpinoſa*, and which Linnæus and Miller call *ulex*, propagate themſelves ſo rapidly, by ſowing their ſeeds, that, where they are once eſtabliſhed in a ſpot of ground, they ſoon over-ſpread the whole place; for, as the ſeeds ripen, their pods are opened by the warmth of the ſun, and they are thrown out with an elaſtic jirk to a conſiderable diſtance all around. There they vegetate, and the ground is ſoon filled with young plants, which are not eaſily deſtroyed after they have taken good root. The only way of extirpating them, is by paring off and burning the ſurface of the ground. *See the article* BURN-BAKING.

This is by ſo much the more adviſable, as theſe ſeeds will otherwiſe remain a long while ſound in the earth, and grow whenever they are brought up by ploughing; and alſo becauſe the ſmalleſt fragments of this plant will ſtrike out freſh roots, and ſhoot up anew: but when a good thickneſs of the ſurface is pared off, and burnt, the ſeeds are ſo effectually deſtroyed, and the roots are killed to ſo conſiderable a depth, that neither can again give riſe to new plants; and if a few of theſe do appear, a ſummer fallow will put an entire end to their growth. Their increaſe may likewiſe be prevented by good manuring with marl, chalk, or lime, eſpecially in ſandy ſoils, which are the moſt apt to produce this plant, and which are at the ſame time the moſt benefited by theſe helps.

However, this very plant, formerly deemed a great nuiſance, is now cultivated to advantage on light, ſandy dry ſoils, which would otherwiſe turn to little account. The tops of the common Engliſh furze, bruiſed a little, to take off, or to blunt their prickly tips, have been found to be excellent fodder, even for lean ſickly beaſts, and particularly horſes, which they have frequently recovered, and plumped up in a ſhort time. This cuſtom is much practiſed in ſeveral foreign countries, where furze are cultivated purpoſely for fodder; and the peaſant thinks it a happineſs, that his breaking their ſpikes with a mallet enables him to give this wholeſome green food to his cattle in the winter, when often no other ſucculent plant can be had fit for that uſe. The mills which Sir Capel Hanbury has lately erected for this end in Wales, with a patri-

otic

otic ſpirit, well ſuited to his diſtinguiſhed zeal for the public welfare, will ſave the countryman that laborious taſk, and prove highly beneficial to thoſe who follow his judicious example.

When furze are raiſed on purpoſe for the food of cattle, and eſpecially on ſoils like the above mentioned, their ſeeds ſhould be ſown in February, March, or April, and the ground ſhould be prepared as for barley. Six pounds of them will be ſufficient for an acre of land; and they ſhould be but barely covered over. The young plants muſt be preſerved from cattle during the firſt year, and they will be fit to mow or cut in the next. October is the proper time to begin cutting them. They will continue to ſhoot till Chriſtmas, and be fit for uſe till March. Horſes eat them as readily as they do hay, after they have been bruiſed, or pounded, ſo as to take off their ſharp points; and it is ſaid, that an acre of ground will produce fifteen tons of this fodder, and that it will go as far as an equal quantity of hay. Some mix the bruiſed furze with chopped ſtraw; an hundred of ſtraw to a ton of furze; but only the growth of the year ſhould be cut for cattle.

Poor hungry gravelly ſoils, which would not have let for five ſhillings an acre, have been rendered worth twenty ſhillings an acre, by ſowing them with furze ſeed, in places where fuel has been ſcarce; this being frequently uſed for heating ovens, burning lime and bricks, and alſo for drying malt; but it is not worth cultivating in countries where fuel of any kind is cheap, or upon ſuch lands as will produce good graſs or corn.

Some years ago, the common furze uſed to be much own for hedges about fields; and where the ſoil was light, he plants ſoon became ſtrong enough for a fence againſt cattle: but as theſe hedges grow naked at the bottom in a ſhort time, and the plants frequently failed, ſo as to leave conſiderable gaps, this practice has of late been greatly diſuſed. The ſpecies commonly called French furze is the beſt for this purpoſe, becauſe it thickens more near the ground, and grows to a greater height; but its ſhoots are not tender enough for cattle to eat them. This is alſo conſidered as the moſt difficult to extirpate: though Mr. Bradley, who tells us he had ſeen fields of one hundred and fifty acres planted with it in Devonſhire, ſays, that it may be killed by cutting the woody ſtalks within a foot of the root in ſummer time; for that it will not then ſpring up again like the ſmall wild furze or whins, by which name Mr. Markham diſtinguiſhes the ſmaller from the larger ſort. This begins to blow in the middle of January, and continues in bloſſom all the ſummer; while the Engliſh furze does not bloom till towards the end of the ſpring, and finiſhes its bloſſoming at the ſame time as the other.

The marquis of Tourbilly obſerves, that cows, oxen, and moſt other cattle, as well as horſes, feed heartily upon, and are well fed by, the bruiſed tops of furze; and that we may be ſure corn will do well wherever this plant is met with: for be the ſurface of ground what it will, the ſpontaneous growth of the furze always indicates a depth of good mould underneath; and the continual dropping and rotting of the leaves, will infallibly improve and enrich the ſurface. The flowers of the furze are excellent for bees.

FUZZEN, *or* FUZEN, the natural juice or nouriſhment of any thing; the ſtrength of it.

G.

GALLERY, a kind of covered walk in a garden, formed into porticoes or arches, with horn-beams, lime-trees, or the like.

GALLING *of a horſe's back*, a diſorder occaſioned by heat, and the chafing or pinching of the ſaddle.

In order to prevent it, ſome take a hind's ſkin well garniſhed with hair, and fit it neatly under the pannel of the ſaddle, ſo that the hairy ſide be next the horſe.

When a horſe's back is galled upon a journey, take out a little of the ſtuffing of the pannel over the ſwelling, and ſew a piece of ſoft white leather on the inſide of the pannel; anoint the part with ſalt butter, and every evening wipe it clean, rubbing it till it grow ſoft, anointing it again with butter, or, for want of that, with greaſe: waſh the ſwelling, or hurt, every evening with cold water and ſope, and ſtrew it with ſalt, which ſhould be left on till the horſe be ſaddled in the morning.

GALLON, a meaſure of capacity both for dry and liquid things, containing four quarts; but theſe quarts, and conſequently the gallon itſelf, are different, according to the quality of the thing meaſured: for inſtance, the wine gallon contains 231 cubic inches, and holds eight pounds avoirdupoiſe of pure water: the beer and ale gallon contains 282 ſolid inches, and holds ten pounds three ounces and a quarter avoirdupoiſe, of water; and the gallon for corn, meal, &c. $272\frac{1}{4}$ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOWS *of a plough*, a part of the plough-head, ſo called by farmers, from its reſemblance to the common gallows, as conſiſting of three pieces of timber, of which one is placed tranſverſely over the heads of the other two. *See* PLOUGH.

GAP, a breach or opening made in a hedge.

GARGET, or *Gargol*, a diſtemper incident to hogs; and is known by the creature's hanging down of his head, and carrying it on one ſide, moiſt eyes, ſtaggering, and loſs of appetite.

It is occaſioned by a corruption of the blood, engendered by

PLATE XVII.

Fig. 2. Glanders.

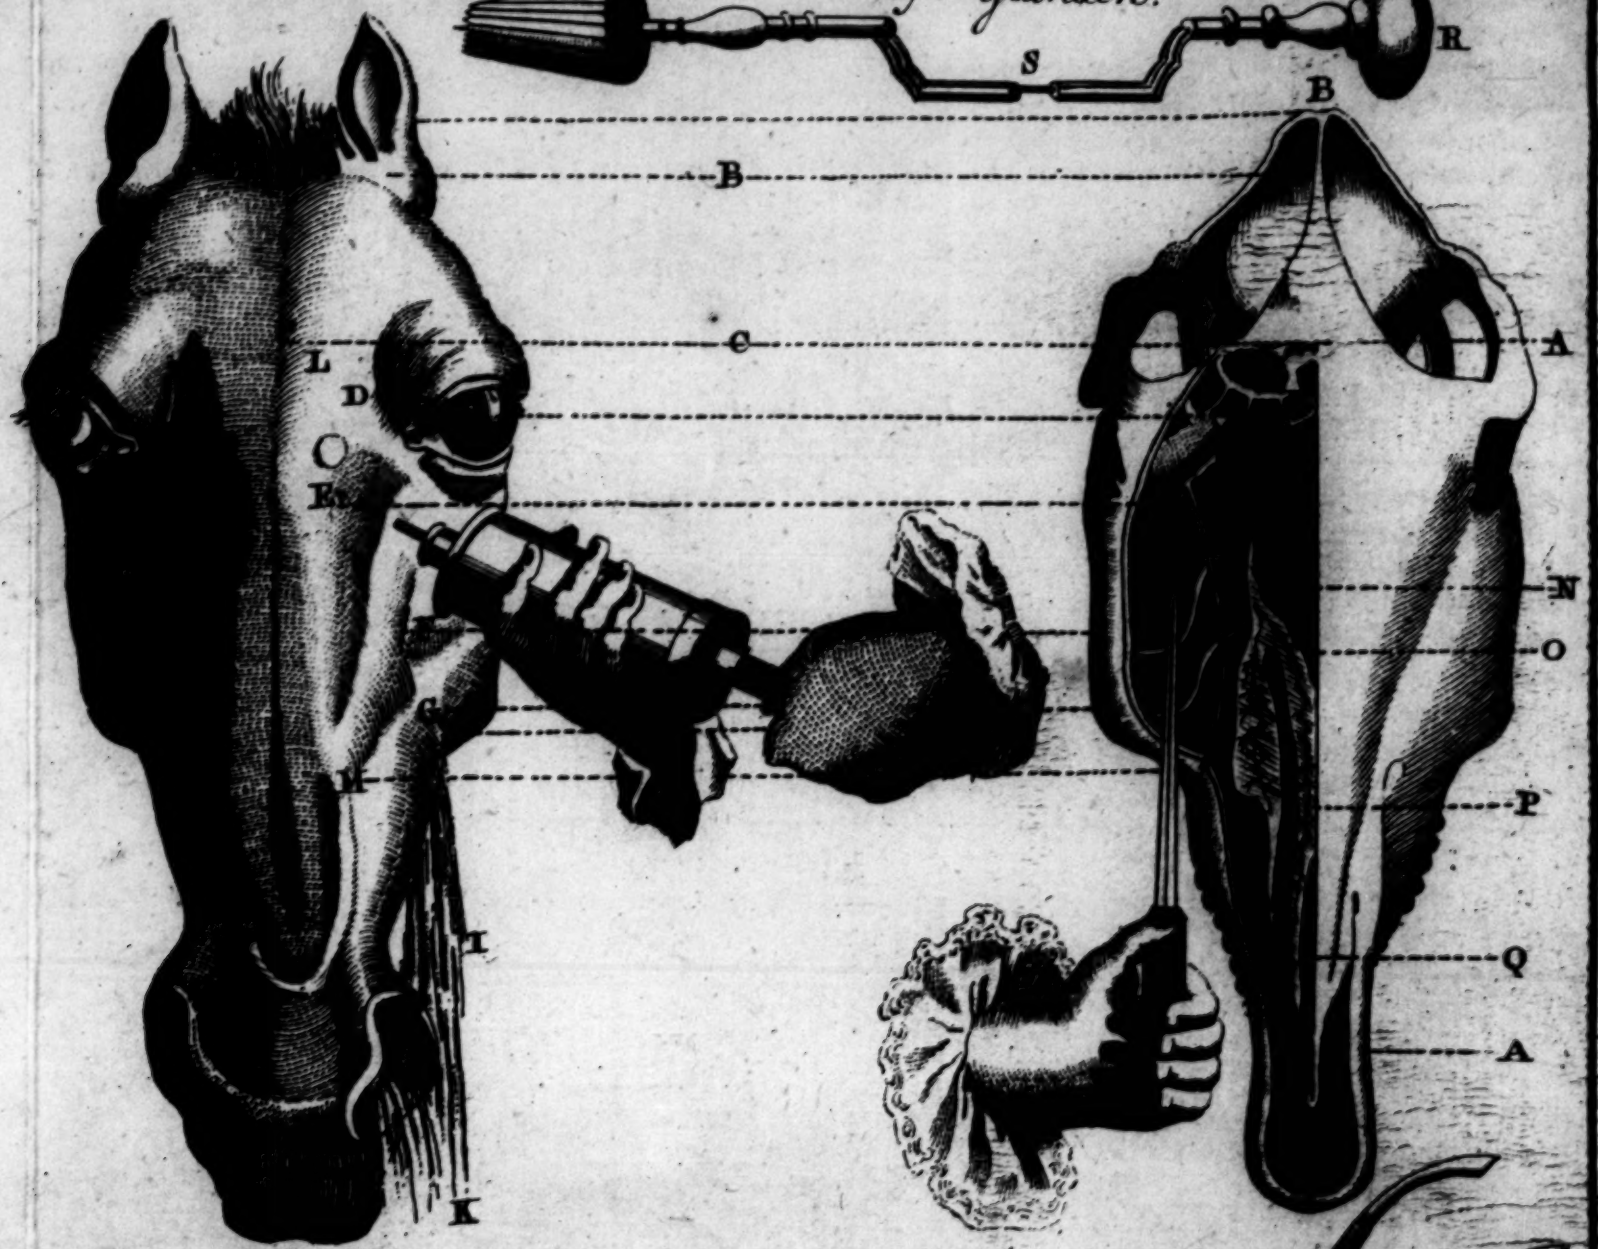

Fig. 4. Hoe-plough.

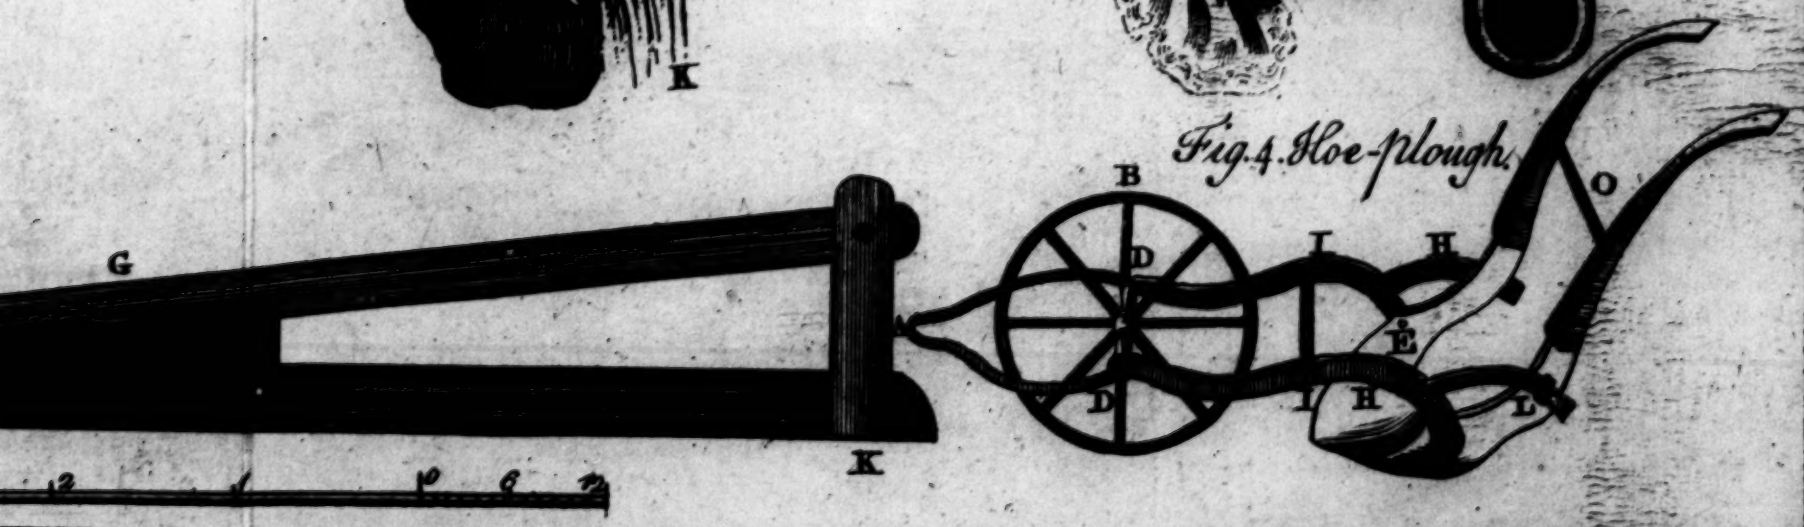

the Scutcher.

by the eating of rotten fruits, garbidge, carrion, or rank graſs, wherein is much hemlock, &c.

In order to cure this diſeaſe, let the creatures be firſt blooded both under the tail and under the ears, and then the following drink given them:

Take of chamber-lye one pint: rue and ſouthernwood, cut ſmall, of each a handful; wood-ſoot from an oven, and common ſalt, of each a ſpoonful; hen's dung, near two ſpoonfuls; flowers of brimſtone one ounce: ſtir the whole together, and give two or three horns to each, proportional to their ſize. It is alſo good for a cow to cure the gargal or murrain.

Or you may uſe the following drink in the room of the above;

Take angelica, rue, ſtavewort, or hog's madder, and May-weed, of each one handful; ſhred them very ſmall, and boil them very well in a pint of milk; and when it is cold enough, add to it a pennyworth of ſallad-oil, and the ſame quantity of treacle. *Mortimer's Huſbandry, vol.* I. *pag.* 250.

GARTH, a yard, a backſide, a croft.

GARNER, a granary, or repoſitory for corn.

GARZIL, hedging wood.

GATE, a frame of timber upon hinges to give a paſſage into incloſed grounds.

GATEWAY, the paſſage through gates of incloſed grounds.

GATTERIDGE-TREE, prickwood.

GAVEL, a row, or ſwarth of corn cut down with the ſcythe.

GAVEL, is alſo a provincial word, ſignifying ground.

GAVEL-KIND, a cuſtom whereby the lands of the father are equally divided at his death among all his ſons.

GAVELOCK, a pitch, or iron-bar for entering ſtakes into the ground.

GEESE, birds too well known to need any deſcription here. They are very profitable to the farmer many ways, for their fleſh, their feathers, and their greaſe. They will live upon commons or any ſort of paſtures, and need very little care or attendance; only they ſhould have plenty of water. The largeſt geeſe are reckoned the beſt: but there is a ſort of Spaniſh gooſe, that is a much better layer and breeder than the Engliſh, eſpecially if the eggs are hatched under an Engliſh gooſe.

Geeſe lay in the ſpring, the earlier the better; becauſe of their price, and their having a ſecond brood. They commonly lay twelve or ſixteen eggs apiece. You may know when they will lay, by their carrying ſtraw in their mouth; and when they will ſit, by their continuing on their neſts after they have laid. A gooſe ſits thirty days; but if the weather be fair and warm, they will hatch three or four days ſooner. After the goſlins are hatched, ſome keep them in the houſe ten or twelve days, and feed them with curds, barley-meal, bran, &c. and after they have acquired ſome ſtrength let them out four or five hours a day, taking them in again till they are big enough to defend themſelves from vermin. Others put them out at firſt, and perhaps ſucceed as well as the former. One gander will be ſufficient for five geeſe.

If you would fat green geeſe, you muſt ſhut them up when they are about a month old, and they will be fat in about a month more. Be ſure to let them have always by them, in a ſmall rack, ſome fine hay, which will much haſten their fatting. But for fatting of older geeſe, it is commonly done when they are about ſix months old, in or ſoon after harveſt, when they have been in ſtubble fields, from which food ſome kill them, which is a good way. But thoſe who are deſirous of having them very fat, ſhut them up, for a fortnight or three weeks, and feed them with oats, ſplit beans, barley-meal, or ground malt mixed with milk; but the beſt thing to fatten them with is malt mixed with beer. You muſt however obſerve in fattening all ſorts of water-fowl, that they uſually ſit with their bills upon their rumps, where they ſuck out the greater part of their moiſture and fatneſs, at a ſmall bunch of feathers, which you will find ſtanding upright on their rumps, and always moiſt, with which they trim their feathers, which renders them more oily and ſlippery than the feathers of other fowls, and cauſes the water to ſlip off them. If therefore theſe upright feathers are cut away cloſe, they will become fat in leſs time, and with leſs meat than otherwiſe. Geeſe will likewiſe feed on, and fatten well with carrots cut ſmall and given them; or if you give them rye before, or about Midſummer, it will ſtrengthen them, and keep them in health, that being commonly their ſickly time.

In ſome countries they ſhear their geeſe for feathers, and ſome pull them twice a year; but the latter is more injurious to them, and therefore it is better ſtaying till their moulting time, and till their death, for the feathers. *Mortimer's Huſbandry, vol.* I. *pag.* 255.

GELDING, a caſtrated animal. For the method of gelding horſes, *ſee the article* HORSE.

GELT-GIMMER, a barren ewe.

GEOFF, or *Goffe*, a mow of hay or corn.

GERMINATION, the act of ſprouting or ſhooting; growth.

GERMINS, buds, tender ſhoots.

GIGGS, ſmall ſwellings, or bladders on the inſide of the lips and palate of a horſe.

They are cured by ſlitting them open with a knife or lancet, and waſhing them afterwards with ſalt and vinegar.

GILL, a rivulet, a beck. It is alſo a name for ground-ivy, or ale-hoof.

GIMMER-LAMB, or *Gammer-Lamb*, an ewe-lamb.

GLANDERS, a very obſtinate and loathſome diſeaſe incident to horſes.

The cauſe and ſeat of the glanders has till lately been ſo imperfectly handled, and ſo little underſtood by the writers on this diſtemper, that it is no wonder it ſhould be ranked among the incurables: but a new light having been thrown on this whole affair by the ſtudy of M. La Foſſe, the king of France's farrier, who has been at the pains to trace out, and diſcover, by diſſections, the ſource and cauſe of this diſorder, we hope the method he has propoſed, with ſome further experiments and improvements, will ſoon bring to a certainty of cure (in moſt caſes at leaſt) a diſtemper ſo dangerous to our horſes, and that hitherto has eluded the force of art.

Before we make mention of this work, which has the approbation of the Royal Academy of Sciences, it will not be unacceptable to our readers, we apprehend, to have a more particular account of the ſymptoms of this diſorder

from M. La Foſſe, that we may the better judge of the merit of our author and his diſcoveries.

This gentleman then has diſtinguiſhed ſeven different kinds of glanders, four of which are incurable.

The firſt proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is diſcharged through the noſtrils, like a whitiſh liquor, ſometimes appearing in lumps and grumes. In this diſorder, though the matter is diſcharged from the noſtrils, yet the malady is ſolely in the lungs.

The ſecond is a waſting humour, which uſually ſeizes horſes at the decline of a diſeaſe, cauſed by too hard labour; this defluxion alſo proceeds from the lungs.

The third is a malignant diſcharge, which attends the ſtrangles ſometimes, and falls upon the lungs, which runs off by the noſtrils.

The fourth is, when an acrimonious humour in the farcy ſeizes theſe parts, where it ſoon makes terrible havock.

The fifth kind we ſhall deſcribe by and by, as ariſing from taking cold.

The ſixth kind is a diſcharge from the ſtrangles, which ſometimes vents itſelf at the noſtrils.

Theſe are the various diſorders which have been obſerved ſometimes to throw matter out from the noſtrils; let us now deſcribe the real glanders:

The matter then diſcarged from the noſtrils of a glandered horſe, is either white, yellow, or greeniſh, ſometimes ſtreaked, or tinged with blood; when the diſeaſe is of long ſtanding, and the bones are fouled, the matter turns blackiſh, and becomes very fœtid; and is always attended with a ſwelling of the kernels or glands under the jaws; in every other reſpect the horſe is generally healthy and ſound, till the diſtemper has been of ſome continuance.

It is always a bad ſign, when the matter ſticks to the inſide of the noſtrils, like glue or ſtiff paſte; when the inſide of the noſe is raw and looks of a livid, or lead colour, when the matter becomes bloody, and ſtinks, and when it looks of an aſh colour. But when only a limpid fluid is firſt diſcharged, and afterwards a whitiſh matter, the gland under the jaw not increaſing, and the diſorder of no long continuance, we may expect a ſpeedy cure; for in this caſe, which ariſes from taking cold, after a horſe has been overheated, the pituitary membrane is but ſlightly inflamed, the lymph in the ſmall veſſels condenſed, and the gland overloaded, but not yet ulcerated.

From theſe ſymptoms and ſome obſervations made both by Bracken and Gibſon, it is plain they were not abſolute ſtrangers to the ſeat of this diſorder, though they neglected puſhing their inquiries to the fountain-head, and conſequently were at a loſs to know how to apply the remedy to the parts affected.

But our author, after examining by diſſection the carcaſes of glandered horſes, and making a ſtrict ſcrutiny into the ſtate of the viſcera, aſſiſted for that purpoſe by ingenious and expert anatomiſts for ten years together, affirms this diſeaſe to be altogether local; and that the true ſeat of it is in the pituitary membrane, which lines the partition along the inſide of the noſe, the maxillary ſinuſſes or cavities of the cheek-bones on each ſide the noſe, and the frontal ſinuſſes or cavities above the orbits of the eyes; that the viſcera, as liver, lungs, &c. of glandered horſes are in general exceeding ſound; and conſequently that the ſeat of this diſorder is not in thoſe parts, as has been aſſerted by moſt authors; nor indeed is it probable it ſhould: for how could ſuch horſes preſerve their appetite, their good appearance, ſleek and ſhining coats; in a word, all the ſigns of health for many years together (which many glandered horſes are known to enjoy) with ſuch diſtempered bowels.

But on nicely examining the heads of ſuch horſes, he found the cavities above-mentioned, more or leſs, filled with a viſcous ſlimy matter, the membrane which lines both them and the noſtrils inflamed, thickened, and corroded with ſordid ulcers, which in ſome caſes had eat into the bones. Theſe ſinuſſes or cavities will be better underſtood by referring to the annexed plate.

He obſerves, that when glandered horſes diſcharge matter from both noſtrils, both ſides of the membrane and cavities were affected; but when they ran at one noſtril only, that ſide only was found diſtempered.

It is a curious remark of our author, that the ſublingual glands, or the kernels ſituated under the jaw-bone, which are always ſwelled in this diſtemper, do not diſcharge their lymph into the mouth, as in man, but into the noſtrils; and that he conſtantly found their obſtruction agreed with the diſcharge; if one gland only was affected, then the horſe diſcharged from one noſtril only; but if both were, then the diſcharge was from both.

He ſometimes, though rarely, found the boney partition of the noſe carious or rotten; but that the ſpongy bones about this part muſt ſuffer from the acrimony of matter long pent, is not at all to be doubted, though the more ſolid ones may eſcape.

The ſeat of this diſorder thus diſcovered, our author, with great ingenuity, has paved the way for cure, by trepanning theſe cavities, and taking out a piece of bone, by which means the parts affected may be waſhed with a proper injection; and, in fine, the ulcers deterged, healed, and dried up.

But as from the obſervations ſince made by this gentleman, there are different ſpecies of the glanders; ſo the cure of the milder kinds may firſt be attempted by injections and fumigations. Thus, after taking cold, ſhould a horſe for fifteen or twenty days diſcharge a limpid fluid, or whitiſh matter from one or both noſtrils, the glands under the jaw rather growing harder than diminiſhing, we may expect it will degenerate into a true glanders: to prevent which, after firſt bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with a decoction of linſeed, marſhmallows, elder, chamomile flowers, and honey of roſes, or ſuch like, be thrown up as far as poſſible with a ſtrong ſyringe, and repeated three times a day: ſhould the running not leſſen, or be removed in a fortnight by the uſe of this injection, a reſtringent one may now be prepared with tincture of roſes, lime-water, &c. and the noſtrils fumigated with the powders of frankincenſe, maſtich, amber, and cinnabar, burnt on an iron heated for that purpoſe, the fume of which may eaſily be conveyed through a tube into the noſtrils.

This method has been found ſucceſsful when uſed in time; but the methods of cure depend on the ſtubborneſs of the diſorder; and, when inveterate, recourſe muſt be had to the operation above deſcribed.

This operation he has performed on three horſes, two of whom diſcharged from one noſtril only, and the third from both; the two firſt he trepanned on that ſide of the head which was affected, and to the other he performed it

on both, and found that the wound and perforation filled up with good flesh in twenty-six days, and the horses suffered no inconvenience from the operation; though after this experiment they were put to death.

The directions and orders of the civil government of France, which hinder people from keeping glandered horses, long prevented M. La Fosse repeating his attempts, and pushing his experiments further; but it is to be hoped that so useful a project will be pursued to its utmost extent, as it seems so promising in the execution, and is so important in its consequences: to which end we shall beg leave to animadvert on what has been said, and offer our opinion both in relation to the disease, the operation, and the manner in conducting the cure.

In order to prove that a great inflammation of the pituitary membrane is always the cause of the glanders. M. La Fosse has attempted to bring on an inflammation upon the same membrane, by a corrosive injection; and when the injection was only thrown into one side, the maxillary lymphatic glands were swelled on the same side, and that nostril only produced the discharge; but when both nostrils were injected, these symptoms appeared on both sides. This gentleman has also observed, that the bone of the maxillary sinus being broke by the kick of another horse, the usual symptoms of the glanders soon appeared, from the inflammation the pituitary membrane suffered on the occasion.

The original source and cause then of this disorder seems to be an inflammation in the glands, and membrane that lines the nostrils and these cavities, which, if not dispersed in time, will form matter, and ulcerate and erode the bones, for want of a free discharge to unload the cavities, and of proper applications to cleanse and deterge the ulcers: violent cold, or a feverish translation settling here, may also occasion the same complaint, and are probably the general causes.

There is a disorder in men called *Ozæna*, that has great similitude to this in horses, and arises from an inflammation in the maxillary sinusses, or cavities in the cheek-bones, from whence ensues a collection of matter, which, when the cavity is full, or the head properly inclined, runs over into the nose, and would constantly discharge thence like a glandered horse, was the head continued in the same position. The surgical cure is the taking out one or more teeth from the upper jaw, and perforating the cavity with a proper instrument, in order to make a depending orifice for the matter to flow through; and to make way for syringing the parts affected with proper injection, which in this case are thrown through the cavity into the nose.

The similarity of these two cases, with the method of cure, and the success attending the surgical treatment (which was first invented and perfected by our countrymen Drake and Cowper) undoubtedly gave the first hint for trepanning, and syringing these cavities in horses; and it is most probable, that when the operation is attempted in time, before the bones become rotten, it will be attended with equal success; but after opening the cavities, should it by probing be discovered, that the bones are in that state, the best way then would be to dispatch the horse, to prevent unnecessary trouble and expence.

The parts fixed on for applying the trepan are pointed out in the plate, and the manner of sawing out the bone will easily be understood by a view of the instrument, and the explanation annexed.

The perforations being made, our next business is to prevent their filling up too fast, as it may be necessary to keep them open for some weeks before a cure can be affected; for which purpose, after the use of the injection, let the upper one be filled up with a piece of cork, waxed over, and adapted exactly to its size, the lower one may be kept open with a hollow leaden tent, through which there will be a constant drain of matter from the sinus's, which will be greatly favoured by this depending orifice, and both be detained by a proper bandage.

If this method should not prevent the granulations, or shoots of the flesh, from filling up so fast as to choak up the perforation, and by that means hinder the injections passing freely, they must be suppressed by rubbing with caustic medicines, or touching with the actual cautery; as may also the bony edges, which, by obliging them to exfoliate or scale off, will retard the healing.

The injection first made use of, should be of a detersive nature; as a decoction of birth-wort, gentian, and centaury; to a quart of which, if two ounces of Ægyptiacum and tincture of myrrh are added, it may be as proper as any; and when the discharge is observed to abate, and the colour alter to a thick white matter, the injection may be changed for barley-water, honey of roses, and tincture of myrrh; and, finally, to dry up the humidities, and recover the tone of the relaxed glands, Bate's allum-water, or a solution of colcothar, vitriol, lapis medicamentosus, or such like, in lime-water, will most probably complete the cure. Dr. Bracken recommends the following:

> Take of allum and white vitriol powdered, of each four ounces, calcine them in a crucible when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar, decant the clear for use.

But whoever is at all acquainted with practical surgery, well knows, that without the assistance of internals, especially in glandular disorders, the cure is not so easily effected, nor rendered complete or lasting: we therefore advise a strong decoction of guaicum chips to be given every day, to a quart or three pints, throughout the cure, and then the matter lessens, to purge at proper intervals, and put a rowel into the horse's chest, in order to divert the fluids from their old channel; if these should not succeed, mercurials may be given with the physic, and the alterative powders with lime-water may be taken for a time, if the horse is worth the expence.

An Explanation of the Heads and Trepan. See Plate XVII. *Fig.* 2.

B. B. two lines representing the bounds of the cerebellum, or back part of the brain, which is very small in a horse, in proportion to that of a man, as well as the brain itself, which commences from the line D.

C. C. a line where the superior part of the sinus frontalis commences, together with a view of the bottom of the sinus, which terminates between the lines D and E, where there appears a substance in the form of a pear, which is the os ethmoides, or sieve-like bone, through which the olfactory nerves pass, by which the petuitary membrane receives its sensibility, and the sense of smelling is performed.

E. represents the beginning of the maxillary sinus, which terminates at M.

The ſhaded ſpace, which may be obſerved between theſe two lines, repreſents the great cavities. The oblique ray marked F, is a bony partition, which ſeparates this ſinus into two parts, that have no communication; and ſometimes it happens (though but rarely) that there are two bony partitions; and for this reaſon they are repreſented by the lines marked F and G. It alſo ſometimes happens (but ſtill more ſeldom) that there are horſes, in whoſe heads we do not find any of theſe bony partitions.

N. points out the place of the cornets or horns. O the red oublings. P their middle part. Q the inferior part of them. M the bony canal or pipe which guards the maxillary nerve.

A. A. the ſeptum narium, or partition, which divides the noſe from top to bottom, and conſtitutes the two noſtrils.

L, in the head that is intire, points out where the trepan ſhould be applied on the frontal ſinus, when we have reaſon to believe the glanders is ſpread into this ſinus. However, I think it ſafeſt to apply it firſt on E, for the reaſons mentioned in the next explanation, and becauſe the brain may be endangered, ſhould the ſinus be miſtook.

E, the place where the trepan may be applied, in order to cleanſe the maxillary ſinus. The round mark between D and E (which is the impreſſion of the trepan) is, however, on experience, preferred by the author, as the propereſt place, as one orifice would then be ſufficient to waſh all the parts, both above and below, with the injection.

But in general, when the maxillary ſinus only is affected, penetrate but the upper part, where the ſyringe points, or thereabouts, and your expectations will be anſwered; ſhould they not, there ſeems ſo little danger in the operation, that you may again perforate at the places above mentioned, higher up. But a proper number of experiments will ſoon ſettle this point with certainty.

H, in the head that is intire, points out the place where another hole, or perforation ſhould be made, as a drain to give iſſue to the glanderous matter waſhed away by the injection which could not be diſcharged without ſuch a depending orifice; and perhaps this perforation alone, in many recent caſes, would be ſufficient, provided the injection paſſed freely upwards, and the hole was kept open by means of a hallow leaden pipe conſtantly retained in it for that purpoſe, and to procure a free paſſage for the matter.

I, repreſents the injection puſhed in by the ſyringe, which flows out by the orifice and the noſtril K; during the uſe of the ſyringe, it is neceſſary to hold the noſtrils cloſe.

If, in the maxillary ſinus, inſtead of one there happens to be two bony partitions, it is abſolutely neceſſary to pieree through them both, by means of a ſtiletto, or ſharp-pointed tuck, as in the manner repreſented in the cut of a horſe's head opened, though this conformation ſeldom occurs.

As theſe bony partitions may in ſome particulars vary, ſhould the ſtiletto not have the deſired effect, and the injection thrown in by the ſyringe not come out at H; in ſuch caſe the liquor ſhould be injected upwards, through the orifice made by the ſtiletto or trepan at H.

As in young horſes the frontal and maxillary ſinuſſes are very ſmall, it will be proper to direct the trepan towards the interior part of the noſe, otherwiſe the inſtrument might work upon the roots of the teeth, which incline towards the ſinus, and would in ſuch caſe be an inſurmountable obſtacle to the operation.

R, the inſtrument or trepan. S, the handle which turns it. T, the ſaw-part to be applied to the bone.

From a view of this inſtrument, the manner of working it will appear ſimple and eaſy; the cooper's managing his wimble being a proper directory.

The inſtrument called the trephine, which is chiefly uſed by our Engliſh ſurgeons in perforating the ſkull, will equally anſwer this purpoſe; and if any difficulties ſhould ariſe, notwithſtanding this deſcription, the gentlemen of the faculty will ſoon make it familiar and intelligible.

Before the application of the trepan, or trephine, it is quite neceſſary to obſerve, that a circular piece of the ſkin ſhould firſt be cut off, with the membrane which covers the bone, about the ſize of a half crown piece, in order to make the inſtrument work the eaſier, and to prevent the inconveniencies which might ariſe from the external wounds healing up too faſt.

The ſyringe ſhould be large enough to contain half a pint of injection.

GLANDIFEROUS, an epithet applied to ſuch trees as bear maſt or acorns. Thus the oak, beech, &c. are called glandiferous trees.

GLEANING, the action of picking up the ears of corn left behind by the gatherers.

GLEBE, properly ſignifies the ſoil or ground in general; but is particularly applied to the land poſſeſſed as part of the revenue of an eccleſiaſtical benefice.

GLEBOUS, or *gleby*, turfy.

GLEDE, a kite.

GLEN, a valley, a dale.

GLYSTER, or *Clyſter*, a medicine injected into the anus of an animal.

Glyſters are often neceſſary for horſes in various diſorders, and may be reduced to theſe different kinds, viz. laxative and emollient, purgative and reſtringent.

But it ſhould be obſerved, that before the adminiſtration of emollient glyſters in coſtive diſorders, a ſmall hand well oiled ſhould be paſſed up the horſe's fundament, in order to bring away any hardened dung, which otherwiſe would be an obſtacle to the clyſter's paſſage.

A bag and a pipe of a proper form, is to be preferred to a ſyringe, which throws up the clyſter with ſo much force, that it often ſurpriſes a horſe, and makes him reject it as faſt as it goes in: whereas the liquor, when preſſed gently from the bag, gives him no ſurprize or uneaſineſs, but paſſes eaſily up into the bowels, where it ſometimes remains a long time, and is extremely uſeful, by cooling and relaxing them; and will ſometimes incorporate ſo with the dung, as not eaſily to be diſtinguiſhed from the other contents of the guts. Theſe emollient clyſters are extremely ſerviceable in moſt fevers, and greatly preferable to purging ones; which in general are too pungent, and ſtimulate too much, eſpecially if aloes are a part of the compoſition.

Nutritive clyſters are very neceſſary, and often ſave a horſe from ſtarving, when his jaws are ſo locked by convulſions, that nothing can be conveyed by the mouth.

They ſhould not exceed a quart or three pints at a time, but be often repeated: nor ſhould they be too fat; but made of ſheeps heads, trotters, or any other meat broths, milk-pottage, rice-milk ſtrained, and many other ſuch nouriſhing things. For an emollient clyſter take the following:

Take

Take marſhmallows and chamomile flowers, each a large handful; bay-berries and ſweet fennel-ſeeds bruiſed, each an ounce, boil in a gallon of water to three quarts, pour off into a pan, and diſſolve in it half a pound of treacle, and a pint of linſeed oil, or any common oil.

To make it more laxative, add four ounces of lenitive electuary, or the ſame quantity of cream of tartar, or common purging ſalts.

Take two or three handfuls of marſhmallows, ſenna one ounce, bitter apple half an ounce, bay-berries and anniſeed bruiſed, each an ounce, ſalt of tartar half an ounce; boil a quarter of an hour in three quarts of water, pour off, and add four ounces of ſyrup of buckthorn, and half a pint of oil.

This clyſter will purge a horſe pretty briſkly; and may be given ſucceſsfully, when an immediate diſcharge is wanting; eſpecially in ſome fevers with inflamed lungs, or other diſorders, which require ſpeedy relief.

But it is neceſſary to caution againſt a ſolution of coarſe aloes for this purpoſe, as it has been found to gripe horſes violently, and excite feveriſh, and ſometimes convulſive ſymptoms; and indeed all pungent and ſtimulating medicines, as the ſtronger purgatives generally are, ſhould be given in this form with great caution.

But the generality of emollient clyſters may be prepared with much leſs trouble; as two quarts of water gruel, with half a pound of treacle, a pint of oil, and a handful of common ſalt, will as effectually anſwer every purpoſe. The following is a reſtringent clyſter.

Take pomegranate-bark, or oak bark, two ounces; red roſe-leaves, freſh or dry, a handful; baluſtines, an ounce; boil theſe in two quarts of water, till one is nearly conſumed; then pour it off, and diſſolve in it four ounces of diaſcordium; to which may be added a pint of Port-wine.

This will anſwer all common caſes, where reſtringents are neceſſary, but ſhould never be given in larger quantities; for the longer clyſters of this kind lie in the bowels, the more efficacious they are. *Bartlet's Farriery, page* 22.

GOAD, a pointed inſtrument with which oxen are driven forward.

GOAR-VETCHES, the ſame with ſummer-vetches. *See the article* VETCHES.

GOAT, a genus of animals, the characters of which, according to Mr. Ray, are theſe; that it is covered with hairs, not with wool; that its horns are leſs crooked than thoſe of the ſheep, and that it has a beard hanging down from its chin, and is of a ſtrong ſmell.

It is very ſingular, that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet ſeem by no means contrived by nature for any ſuch purpoſes.

Goats may be of great advantage to the farmers in ſome parts of the kingdom, as they will live in rocky barren countries, where nothing elſe can get a ſupport for life. They will climb the ſteepeſt rocks, and there browſe upon briars, heath, and ſhrubs of various kinds, which other creatures will not taſte of. They will feed on graſs in paſtures; but, as they love browſing on trees much better, great care muſt be taken to keep them from valuable plantations.

The greateſt advantage of theſe creatures is their milk, which they yield in large quantities; and which is accounted the beſt milk of all animals. They mix this and cows milk together in many parts of the kingdom, and a very valuable kind of cheeſe is made of it. Beſide this, the kids or young goats are very fine food, and the beſt kinds bring forth theſe two or three at a time, and that twice a year.

Goats hair alſo is valuable; it may be ſheared as the wool from ſheep, and is excellent for making ropes that are to be uſed in the water, as they will laſt a great while longer than thoſe made the common way. A ſort of ſtuff is alſo made of it in ſome places. The beſt kind of goats for keeping to advantage ſhould be choſen in this manner: the male ſhould have a large body, his hair ſhould be long, and his legs ſtraight and ſtiff; the neck ſhould be plain and ſhort, the head ſmall and ſlender, the horns large, the eyes prominent, and the beard long. The female ſhould have a large udder, with large teats, and no horns, or very ſmall ones. They ſhould be kept in flocks, that they may not ſtraggle; and they ſhould have good ſhelter both in ſummer and in winter, the heat and cold being both prejudicial to them. They ſhould be coupled in December. They ſhould have no litter in winter, but only a paved floor kept clean. The kids are to be brought up, for the table in the ſame manner as our lambs are. They are recommended to lie among horſes, their ſmell, as ſuppoſed, preventing many diſtempers in thoſe cattle. *Mortimer's Huſbandry, vol.* I. *page* 244.

GOD's-GOOD, yeaſt, or barm.

GOFFE, the ſame with geoff. *See* GEOFF.

GOOL, a ditch.

GOOSE. *See the article* GEESE.

GOOSE-GRASS, or wild tanſy, the name of a troubleſome weed very frequent in clay grounds. The beſt method of deſtroying it is to mow it in ſummer, well dung the land, and never plough it out of heart.

GOSS, or *Gorſe*, the furze.

GOULANS, corn-marigolds.

GRAIN, a general name for all ſorts of corn, as wheat, barley, &c.

GRANARY, a building to lay or ſtore corn in, eſpecially that deſigned to be kept a conſiderable time.

Experimental philoſophy has proved, that the air is the great ſource of corruption; keep out that, and all is kept out; and the moſt corruptible ſubſtances, ſuch as meal, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air-pump.

They have, near Grand Cairo, a magazine or granary, defended with good walls, and called Joſeph's granaries. It is not probable that they are quite ſo old as the days of that patriarch; but they abundantly prove the utility of ſuch ſtore-houſes, by the vaſt quantities of grain annually preſerved in them.

Many parts of Africa abound with granaries of this kind.

They are ſo many deep pits made in the ſolid rock; the deſcent into them is but juſt large enough for a man to go down into them; but they grow larger as ſoon as the perſon is in, and are uſually ſquare, from thirty to forty feet in diameter. In theſe the great men of the country preſerve their corn; they firſt ſtrew over the floor with ſtraw, then they lay on the corn, ſtill as the heap riſes, placing a thin bed of ſtraw between the corn and the ſides, as they did at the bottom. In this manner they

proceed

proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a ſort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickneſs of ſand, and over this raiſe a ridge of earth, well beat together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine.

The corn thus ſtored up always keeps three, four, or more years very good; and, not unfrequently, the proprietor being taken off by the ſeverity of the eaſtern governments, under which they live, the magazine is forgotten, and ſome accident diſcovering it many years afterwards, the corn is almoſt always found perfectly good in it. All the care they take, in regard to the corn, is to expoſe it two or three days to the ſun's heat, to dry it thoroughly, before they carry it into the magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preſerve their corn in the ſame manner in wells or pits made in dry places: but in theſe countries great care is to be taken in the opening theſe ſtore-rooms; for if people deſcend into them before they have had ſufficient communication with the freſh air, they are often killed by the damps; this, however, is eaſily guarded againſt. By theſe, and numerous other inſtances of the practice of other countries, it appears evident, that the advantage of theſe ſubterranean granaries over all others is very great.

Though theſe are to be recommended before all others, yet the common granaries may, with proper care, be rendered greatly more uſeful than they are at preſent. The grand caution neceſſary to this purpoſe is, to guard againſt the too great humidity, which there always is in places where there is a great number of doors and windows. A too free acceſs of the external air is alſo to be careſully guarded againſt; for this brings in with it the eggs of a vaſt number of different inſects, which prey upon, and deſtroy the corn. A third caution is, when the corn is the produce of the country where it is preſerved, not to fill the place with the crop of one place only, but to mix the harveſts of two as different provinces as may be, the one dry, the other moiſt, or otherwiſe differing as much as may be; thus the contrary qualities of the one will prevent the deſtruction of the other. Theſe are the three great rules to prevent the corrupting of corn; but when the miſchief is once begun, it will prove very difficult to ſtop it; all the care that can be employed, ſhould therefore be taken in regard to theſe.

The two great cautions to be obſerved in the erecting of granaries, are to make them ſufficiently ſtrong, and to expoſe them to the moſt drying winds. The ordering of the corn in many parts of England is thus: to ſeparate it from duſt and other impurities after it is threſhed, they toſs it with ſhovels from one end to the other of a long and large room; the lighter ſubſtances fall down in the middle of the room, and the corn only is carried from ſide to ſide, or end to end of it. After this they ſcreen the corn, and then, bringing it into the granaries, it is ſpread about half a foot thick, and turned from time to time about twice in a week; once a week they alſo repeat the ſcreening it. This ſort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the ſeaſon be damp, and now and then ſcreen it again. After about five or ſix months, they raiſe it to five or ſix feet thickneſs in the heaps, and then they turn it once or twice in a month, and ſcreen it now and then. When it has lain two years, or more, they turn it once in two months, and ſcreen it once a quarter, and, how long ſoever it is kept, the oftener the turning and ſcreening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every ſide the heap of corn, and other empty ſpaces, into which they turn and toſs the corn, as often as they find occaſion. In Kent they make two ſquare holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lowet rooms, and ſo up again, to turn and air it the better. Their ſcreens are made with two partitions, to ſeparate the duſt from the corn which falls into a bag; and when ſufficiently full, this is thrown away, the pure and good corn remaining behind.

Corn has, by theſe means, been kept in our granaries thirty years; and it is obſerved, that the longer it is kept, the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the ſuperfluous humidity only evaporating in the keeping. At Zurich, in Swiſſerland, they keep corn eighty years or longer, by the ſame ſorts of methods.

The public granaries at Dantzick are ſeven, eight, or nine ſtories high, having a funnel in the midſt of every floor, to let down the corn from one to another. They are built ſo ſecurely, that though every way ſurrounded with water, the corn contracts no damp, and the veſſels have the convenience of coming up to the walls for their lading. The Ruſſians preſerve their corn in ſubterranean granaries, of the figure of a ſugar-loaf, wide below, and narrow at top: the ſides are well plaiſtered, and the top covered with ſtones. They are very careful to have the corn well dried before it is laid into theſe ſtore-houſes, and often dry it by means of ovens, the ſummer dry weather being too ſhort to effect it ſufficiently.

GRANGE, a houſe or farm furniſhed with granaries and barns for holding corn, ſtables for horſes, ſtalls for cattle, &c.

GRANIFEROUS *Pods*, are ſuch as contain ſmall ſeeds reſembling grain.

GRANIVOROUS, an epithet given to animals that feed on corn or ſeed.

GRASS, a general name for moſt of the herbaceous plants uſed in feeding cattle.

The beſt ſeaſon for ſowing graſs-ſeed is the latter end of Auguſt, and the beginning of September, that the graſs may be well rooted before the froſt ſet in, which is apt to turn the plants out of the ground, when they are not well rooted. This ſeed ſhould be ſown in moiſt weather, or when there is a proſpect of ſhowers, which will ſoon bring the graſs up; for, the earth being at that ſeaſon warm, the moiſture will cauſe the ſeed to vegetate in a few days: but, where this cannot be performed in autumn, the ſeeds may be ſown in the ſpring; towards the middle of March will be a good time, if the ſeaſon proves favourable.

The land on which graſs-ſeed is intended to be ſown, ſhould be well ploughed, and cleared from the roots of noxious weeds, ſuch as couch-graſs, fern, ruſhes, heath, gorſe, broom, reſt-harrow, &c. which, if left in the ground, will ſoon get the better of the graſs, and overrun the land. Therefore, in ſuch places where either of theſe weeds abound, it will be a good method to plough up the ſurface in April, and let it lie ſome time to dry; then lay it in ſmall heaps, and burn it. The aſhes ſo produced

duced, when ſpread on the land, will be a good manure for it. The method of burning the land is particularly uſeful; eſpecially, if it is a cold ſtiff ſoil; but where couch-graſs, fern, or reſt-harrow, is in plenty, whoſe roots run far under ground, the land muſt be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off each ploughing; which is the moſt ſure method to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome under-ground drains to carry off the wet; which if detained too long on the ground, will render the graſs ſour. The method of making theſe drains is preſcribed under the article DRAINING.

Before the ſeed is ſown, the ſurface of the ground ſhould be made level and fine, otherwiſe the ſeed will be buried unequal. The quantity of graſs-ſeed for an acre of land is uſually three buſhels, if the ſeed is clean, otherwiſe there muſt be a much greater quantity allowed; when the ſeed is ſown, it muſt be gently harrowed in, and the ground rolled with a wooden roller; which will make the ſurface even, and prevent the ſeeds being blown in patches. When the graſs comes up, if there ſhould be any bare ſpots, where the ſeed has not grown, they may be ſown again, and the ground rolled, which will fix the ſeeds; and the firſt kindly ſhowers will bring up the graſs, and make it very thick.

Some people mix clover and rye-graſs together, allowing ten pounds of clover, and one buſhel of rye-graſs, to an acre: but this is only to be done where the land is deſigned to remain but three or four years in paſture, becauſe neither of theſe kinds are of long duration; ſo that, where the land is deſigned to be laid down for many years, it will be proper to ſow with the graſs-ſeed ſome white trefoil, or Dutch clover; which is an abiding plant, and ſpreads cloſe on the ſurface of the ground, ſending forth roots at every joint; and makes the cloſeſt ſward of any, and is the ſweeteſt ſeed for cattle: ſo that, whenever land is laid down to paſture, there ſhould always be ſix or eight pounds of this ſeed ſown upon each acre.

The following ſpring, if there ſhould be any thiſtles, ragwort, or ſuch other troubleſome weeds, come up among the graſs, they ſhould carefully be cut up with a ſpaddle before they grow large; and this ſhould be repeated two or three times in the ſummer, which will effectually deſtroy them; for, if theſe plants are ſuffered to ripen their ſeeds, they will be blown all over the ground; their ſeeds having down adhering to them, which aſſiſts their tranſportation; ſo that they are often carried by the wind to a great diſtance, and thereby become very troubleſome weeds to the graſs. For want of this care, how many paſtures may be ſeen almoſt over-run with theſe weeds, eſpecially the ragwort; when a ſmall expence, if applied in time, would have intirely extirpated them! for a man may go over ſeveral acres of land in one day with a ſpaddle, and cut up the weeds juſt below the ſurface of the ground, turning their roots upwards; which if done in dry weather, they will ſoon decay; but this muſt always be performed before the plants come to have their ſeeds formed; becauſe after that many ſorts will live long enough to nouriſh their ſeeds after they are cut, ſo as to ripen them: and there will be a ſupply of weeds for ſome years after, which cannot be extirpated without a much greater expence.

The proper management of paſture land is the leaſt underſtood of any part of agriculture: the farmers never have attended to this, being more inclined to the plough; though the profit attending that has not of late years been ſo great as to encourage them in that part of huſbandry: but theſe people never think of laying down land for paſture, to continue longer than three years; at the end of which time they plough it up again, to ſow it with grain.

Their uſual method is to ſow rye-graſs and treſoil with barley, when they intend to lay down the ground; or ſometimes ſow only clover with the barley; nor is it poſſible to convince theſe people of their error in ſowing corn with this graſs; which they affirm to be uſeful in ſhading the graſs; not conſidering how much the corn draws away the nouriſhment from the graſs: but it is in vain to write to theſe people, who are not to be convinced, either by argument or experiment; ſo much are they led by cuſtom, as not to be led or driven out of their own methods; but, as their practice of huſbandry has greatly leſſened the circumſtances of the farmers, ſo that the lands are daily falling into the hands of the owners, therefore this part of huſbandry ſhould by them be principally attended to, as it may be carried on with much leſs expence: for paſture land requires but few hands to manage; whereas the ſowing of corn is attended with great expence, and the profit is very precarious: but when this is attended with ſucceſs, and the grain at a moderate price, if the whole labour is to be paid for, there will be little coming to the owner for rent, when the ballance is fairly ſtated; but in this moſt gentlemen deceive themſelves, and often ſuppoſe they gain by farming, when, perhaps, the whole rent of the land is loſt: therefore, to avoid the trouble which attends this ſort of huſbandry, it will be the beſt method to turn as much of their land into paſture, as they can; which, by grazing and feeding of ſheep, will be attended with little expence, and a ſure profit.

It is not uncommon for the huſbandman, for want of diſtinguiſhing graſſes for ſeed, to fill his ground with either weeds or bad and imperfect graſſes. Whereas by making a proper choice, he would always have the beſt graſs, and in the greateſt abundance his land will admit of.

In the common way of proceeding, if a farmer wants to lay down his land to graſs, he either takes his ſeeds indiſcriminately from his own foul hay-rick, or ſends to his neighbour for a ſupply. By this means, beſides a certain mixture of rubbiſh, which muſt neceſſarily happen; it is not unlikely, but that what he intends for dry land may have come from moiſt, where it grew naturally, and ſo on the contrary: and the conſequence of this ſlovenly method frequently is, that the ground, inſtead of being covered in one year with a good ſward, is filled with weeds not natural to it, which would never have ſprung up, if they had not been brought thinner.

"Arguments, ſays Mr. Stillingfleet, are never wanting in ſupport of ancient cuſtoms, and I am no ſtranger to thoſe, ſuch as they are, which prejudice and indolence have made uſe of on this occaſion.

"1. Some ſay then, that if you manure your ground properly, good graſſes will come of themſelves. I own they will. But the queſtion is, how long it will be before that happens: and why be at the expence of ſowing what you muſt afterwards try to kill? which muſt be the caſe, ſo long as people ſow all kinds of rubbiſh under the name as hay-ſeeds. Again, if the beſt way is to let the ground take its chance, why is the farmer at the expence of procuring the ſeeds of the white and broad clover, which

which come up in almoſt all parts of England ſpontaneouſly? But if this is allowed not to be the beſt way in relation to clover of any kind, what reaſon can be in nature, why graſs-ſeeds only ought not to be ſown pure?

"2. Others ſay, that it is better to have a mixture of different ſeeds. I will ſuppoſe this to be true. But cannot a mixture be had though the ſeeds be gathered, and ſeparated? and is not a mixture by choice more likely to be proper, than one by chance; eſpecially after a ſufficient experience has been had of the particular virtues of each ſort, of the different kinds of cattle which each graſs is moſt adapted to, of the different grounds where they will thrive beſt, &c. all which circumſtances are now, in general, wholly unknown, though of the utmoſt conſequence?

"3. It is ſaid by ſome, that weeds will come up along with the graſs. No doubt of it. Can any one imagine, that graſs-ſeeds ſhould be exempted from what happens to every other kind of ſeeds? But I will venture to ſay, that not near the quantity of weeds will ſpring up which they imagine, if the graſs be ſown very thick. Men muſt be very much put to it, when they make ſuch objections as this laſt, or indeed any of the others. I am almoſt inclined to ſay with a great writer, It is a ſimple thing to take much pains to anſwer ſimple objections.

"One would hardly think it poſſible, that the ſlovenly method of proceeding, here complained of, could prevail univerſally: yet this is the caſe as to all graſſes, except the darnel (or rye) graſs, and what is known in ſome few countries by the name of the Suffolk graſs; and this latter inſtance is owing, I believe, more to the ſoil than to any care of the huſbandmen. Now, would the farmer be at the pains of ſeparating, once in his life, half a pint, or a pint, of the different kinds of graſs ſeeds, and take care to ſow them ſeparately, in a very little time he would have wherewithal to ſtock his farm properly, according to the nature of each ſoil, and might at the ſame time ſpread theſe ſeeds properly over the nation, by ſupplying the ſeed ſhops.

"I have had frequent experience how eaſy it is to gather the ſeeds of graſſes, having ſeveral times employed children of ten or eleven years old, who have gathered many ſorts for me without making any miſtakes, after I had once ſhewn them the ſorts I wanted.

"I have procured thus the creeping bent, the fine bent, the ſheep's feſcue, the creſted dog-tail, &c. in ſufficient quantities, to begin a ſtock; but, for want of a proper opportunity of cultivating them myſelf, or meeting with any one who had zeal enough to beſtow a proper care on them, my collections of this kind hitherto have only proved, that the ſcheme is in itſelf feaſible.

"In the year 1761, a little boy gathered, by my directions, as much of the creſted dog-tail, in three hours, by the ſide of a road, as when ſhed, yielded, upon weighing, above a quarter of a pound averdupois, perfectly free from huſks. As this ſeed is ſmall, the ſkillful will eaſily judge how far ſuch a quantity would go if properly employed.

"My very eſtimable and ingenious friend Mr. Aldworth, who was witneſs of the fact which I laſt mentioned, at my deſire, ordered a ſmall part of a meadow, near his ſeat at Stanlake, which had better graſſes, and leſs mixed, than the reſt, to be left unmowed till the ſeeds were fit for gathering. This piece yielded, upon threſhing and ſifting, a full buſhel by meaſure, of almoſt pure ſeed of the creſted dog-tail.

"In caſe any one ſhould be inclined to follow this example, I think it highly neceſſary to obſerve, that care muſt be taken to mow the graſs before it ſheds; that it be mowed very early in the morning, before the dew is off the ground, and that it ought not to be ſpread as in making hay, but left as it falls from the ſcythe during a ſufficient time, and then be gently turned over.

"The number of graſſes fit for the farmer is, I believe, very ſmall; perhaps half a dozen, or half a ſcore, are all he need to cultivate; and how ſmall the trouble would be of collecting the ſeeds of theſe, and how great the benefit, muſt be obvious to every one at firſt ſight. Would not any one be looked upon as wild, who ſhould ſow wheat, barley, oats, rye, peaſe, beans, vetches, buck-wheat, turneps, and weeds of all ſorts together? Yet how is it much leſs abſurd to do what is equivalent in relation to graſſes? does it not import the farmer to have good hay and graſs in plenty? and will cattle thrive equally on all ſorts of food? We know the contrary. Horſes will ſcarcely eat hay that will do well enough for oxen and cows. Sheep are particularly fond of one ſort of graſs, and fatten upon it faſter than any other in Sweden, if we believe Linnæus. And may they not do the ſame in England? How ſhall we know till we have tried? Nor can we ſay, that what is valuable in Sweden, may be inferior to many other graſſes in England, ſince it appears by the Flora Suecica, that they have all the good ones that we have. But however this may be, I ſhould rather chooſe to make experiments than conjectures."

The Society for promoting Agriculture, &c. in the province of Brittany, has laid down the moſt rational plan yet formed by any body of men, nobly aſſociated for the welfare of their country, and which promiſes the greateſt advantages to mankind. A part of this plan is the cultivating ſeparately moſt of the plants which grow naturally in the fields there, in order to know which of them will afford the moſt and the beſt food for cattle.

As the huſbandman would not be benefited by knowing the particular claſſes, genera, &c. under which Ray, Linnæus, and other botaniſts have ranged the ſeveral ſpecies of graſſes, we ſhall here give the names of ſuch of them as may be cultivated to moſt advantage in this country, with the beſt drawings (for which we are indebted to Mr. Stillingfleet) of ſome of the moſt profitable ſorts, which it will be of ſervice to the farmer to be able to diſtinguiſh rightly.

The common dogs graſs, quich graſs, or couch graſs (*Gramen ſpicâ triticeâ repens vulgare, caninum dictum*) common creeping graſs, with a ſpike like wheat, called dogs graſs, will thrive in almoſt any ſoil, and can ſcarcely be got out again, after it has once taken poſſeſſion: ſo greatly does it multiply by its roots and trailing branches, which put forth roots and ſhoots at every joint. It grows to the height of four or five feet, with blades ſo rough and coarſe, that few horſes will eat them, eſpecially while they are green: but it yields abundant crops of hay, which does well enough for oxen, and therefore deſerves, perhaps, more attention than our farmers have yet beſtowed upon it. M. Duhamel indicates the beſt way of making the moſt of it, when he directs the farmer always to mow it before its ſeeds ripen, or its ſtalks grow hard; for after that cattle refuſe it; adding, that it ſoon ſhoots up again, and will bear frequent cutting.

This

This plant is well known to all huſbandmen, to whom it is a ſad plague, when it gets into their arable land. It is the chiendent of the French, who, I muſt obſerve here for the benefit of their huſbandry, do not diſtinguiſh it ſufficiently from our

Rye graſs, which is C. Bauhin's *Gramen loliaceum anguſtiore folio, et ſpica*, Darnel graſs, with a narrower leaf and ſpike; and Linnæus's *Lolium ſpicâ muticâ*, Darnel with a chaffy ſpike: for darnel graſs, rye graſs, and ray graſs, are only different names of one and the ſame plant: though M. Duhamel, miſled by the erroneous ſpelling of ſome writers, who have called rye graſs ray graſs, has been miſtakenly induced to think, that theſe are two different plants with us. We diſtinguiſh, indeed, two conſiderably different ſpecies of the rye graſs, viz. the foregoing, which, according to Mr. Ray, is the *Lolium rubrum*, or red darnel; and the *Lolium album*, which, according to the ſame author, is C. Bauhin's *Gramen loliaceum ſpicâ longiore*, darnel graſs, with a longer ſpike, and the yvraie of the French, by us commonly called darnel only. But both of them are equally rye graſs. It is the laſt of theſe ſpecies, viz. the *lolium album*, which is chiefly cultivated in England, eſpecially in ſtrong cold land, upon which it will ſucceed better than any other ſpecies, and is an earlier ſeed in the ſpring: but it is very coarſe; and unleſs it be cut quite early for hay, it becomes ſo hard and wirey in the ſtalks, that few cattle care to eat it: for this ſort of graſs has but few leaves, and runs all to ſtalks. When cattle have been turned in to feed upon it, the remaining ſtalks or bents, as they are ſometimes called, ſhould be mowed off in June; for otherwiſe they will dry upon the ground, give the paſture the diſagreeable appearance of a ſtubble field during all the latter part of the ſummer, and be ſo very tronbleſome to the cattle which feed on it, by tickling their noſtrils, that nothing but the want of better grazing will compel them to eat of the young graſs which ſhoots up between theſe withered ſtems; for they will not eat them. Thoſe who think that they do, when ſtreightened for food, are greatly miſtaken, according to Mr. Miller, who ſays, that he has cloſely attended to this many years, and has always found theſe bents remaining on the ground untouched, till the froſts, rain, and winds, have deſtroyed them in the winter. Beſides this, by permitting them to ſtand, the after growth of the graſs is greatly retarded, and the beautiful verdure of the fields is loſt for three or four months. It therefore is good huſbandry to mow them cloſe to the ground, before they become too dry: and if this cutting is then made into hay, it will ſerve to feed cart horſes in the winter, ſo as to repay the expence of mowing.

The red darnel is a conſiderably inferior ſpecies of rye graſs; for it has yet narrower leaves, and its ſtalks grow hard much ſooner. It is very common in moſt paſture grounds, becauſe it flowers early, and its ſeeds ripen and ſow themſelves before the hay is cut. They, therefore, who would keep their paſtures as clear as poſſible from this graſs, ſhould always mow them before its ſeeds are ripe.

Rye graſs is uſually ſown with clover, upon ſuch lands as are deſigned to be ploughed again in a few years; and a common method is to ſow it with ſpring corn. But Mr. Miller, from many repeated trials, has always found, that when this graſs has been ſown in Auguſt, and a few ſhowers have fallen ſhortly after, the crop has been by much the beſt: for it then has often been ſo high as to afford a good feed the ſame autumn; and a ton and a half of hay has been mowed early the next ſpring on each acre of land, though it has been a cold and ſour ſoil. "I am, therefore, ſays he, convinced of that being the beſt ſeaſon for ſowing theſe graſſes; though it will be very difficult to perſuade theſe perſons to alter their practice, who have been long wedded to old cuſtoms. The quantity of ſeeds which I allow to an acre is about two buſhels, and eight pounds of the common clover, which, together, will make as good a covering upon the ground as can be deſired. But this is not to be practiſed upon lands where the beauty of the verdure is principally regarded. It is fitteſt for thoſe who have only profit in view." However, we muſt reckon as an abatement in this profit, that, as M. Duhamel rightly obſerves, the ground that has been under rye graſs, which is not ſo profitable a crop as either lucerne, ſainfoin, or even clover, is not able to bear wheat the next year, as it is after thoſe other plants, or after a crop of roots."

According to Mr. Liſle's information, the farmers in the Iſle of Wight prefer rye graſs to hop clover, becauſe, ſay they, the rye graſs will bear the winter, and keep to a good head, which the clover will not do. One of his tenants there had an acre and a half of rye graſs upon tolerably good ground, which he ſhut up from Michaelmas till within a month of Candlemas, and from thence to the middle of April it kept fifteen ewes and fifteen lambs.

Rye graſs ſeldom laſts more than three years, as it is commonly managed: but Mr. Liſle is ſtrongly of opinion, that, conſidering the nature of its roots, and its manner of propagating itſelf, by ſending forth fibres from its joints, it may be kept alive many years longer, by dunging it, or by refreſhing it with ſoil, when it begins to decay, after the ſecond or third year: beſides which, this will make its roots tiller, and mat on the ground, to the utter ſuppreſſion and deſtruction of all weeds, not excepting even the couch graſs.

An acquaintance of his near Upcern, in Dorſetſhire, told him, that he had as much rye graſs ſeed on eighteen acres of land, as was worth twenty pounds; and that, after the ſeed was threſhed out, that hay was better than oat-ſtraw fodder. Mr. Liſle himſelf ſaw a rick of this coarſe ſtubbed hay, and a rick of oat ſtraw, both of which had been laid open to the cattle, in the ſame place; and they would not touch the ſtraw, but had made ſuch a hole in the rye graſs hay rick, that it was ready to fall. The ſame perſon aſſured Mr. Liſle, that he found the rye graſs to be excellent food for his cattle, if it was mowed green, and not kept for the lucre of the ſeed. His uſual allowance was three buſhels of this ſeed to an acre of land, and he uſed to ſell it for twenty-two pence, or two ſhillings a buſhel.

Another farmer ſhewed Mr. Liſle ſome of his rye graſs, ſaying, that he looked upon it as his choiceſt fodder for ſheep. He mowed it while in the flower; and Mr. Liſle declares, that he thought it very fine hay. Others again, and thoſe men of experience, have affirmed, that the very ſtubble of the rye graſs, mowed the ſame year it was ſowed, is, when ploughed in, as good as dunging, and will pay for the ſeed.

Mr. Liſle agrees with all other experienced huſbandmen, that, though rye graſs will maintain as many cattle on an acre as hop clover will do; yet it does not, like it, improve the land for a ſubſequent crop of corn; the reaſon of which he takes to be, that the roots of the rye graſs, conſiſting of a multitude of matty fibres, which run on

the ſurface of the ground, gird and hold the earth ſo ſtrongly together, that they cannot eaſily be diſintangled from it by ploughing.

"If I may judge of this graſs, ſays Mr. Stillingfleet, by the veniſon I have eaten out of a paddock that was chiefly filled with this ſpecies, I would by no means recommend it for parks. I know it will be ſaid, that veniſon is never good out of paddock, that the deer muſt have room to range, trees to browſe on, &c. I grant there is ſome reaſon for ſaying this, but I believe in general it is more owing to the want of proper food, viz. good graſs, than merely to confinement; for paddocks are generally made out of a rich ſpot of ground near the houſe, that has conſtantly been manured, and of courſe is full of graſs fitter for the dairy or the ſtable, than for deer; which hardly ever is the caſe in large parks. No man, will, I ſuppoſe, pretend to make good pork from a hog fed with grains inſtead of peaſe, tho' he has the liberty of chooſing as much ground as he pleaſes, and where he pleaſes."

In a ſubſequent edition of his obſervations on Graſſes, he adds, "I have ſince eaten veniſon out of a large park, where there was much of this graſs, and it was no better than that out of the paddock. I ſhould be apt to think from hence, that this graſs would not be proper for ſheep, as I have always obſerved that the ſame kind of ground which yields good veniſon, yields alſo good mutton. For what particular uſes it is good, wants to be tried; whether for the dairy, for fattening cattle, or for horſes. Many are tempted, by the facillity of procuring the ſeed of this graſs, to lay down with it grounds near their houſes, where they want to have a fine turf: but unleſs the ſoil be very rich, a worſe graſs cannot be choſen for this purpoſe, as it will certainly die off entirely in a very few years."

The wall barley, or way bennet, as ſome people improperly term it, is evidently from the ſhape of its ear, and from every other characteriſing circumſtance, a rye graſs, or wild rye, as Mr. Ray obſerves, though very different from the preceeding. It is the *gramen ſecalinum et ſecale ſylveſtre*, called tall meadow rye-graſs by Mr. Miller, who reckons it an excellent graſs for ſowing, becauſe it is very leafy, its ſtalks do not become ſtiff and hard like many other ſpecies, and its roots are perennial. He ſeems not to doubt, but that it may be rendered very fine by proper care; and as its roots are perennial, rolling will make them mat ſo as to form a very cloſe ſward. There are three ſorts of it, viz. the greater, the leſſer, and the marſh rye graſs. Mr. Stillingfleet wiſhes, that this genus only were to be called rye graſs, and that the old name of darnel were continued to the *gramen loliacoum*, or rye graſs, before ſpoken of.

The two beſt ſpecies of graſs for paſtures are, in Mr. Miller's opinion, C. Bauhin's *gramen pratenſe, paniculatum majus, anguſtiore folio*, meadow graſs, with large panicles, and a narrower leaf, which is the *poa paniculâ diffuſâ, ſpiculis, quadrifloribus pubeſcentibus culmo erecto teretri*, Flor. Suec. 77. Poa with a diffuſed panicle, the ſmaller ſpikes having four hairy flowers, and a taper erect ſtraw; and C. Bauhin's *gramen pratenſe, paniculatum majus, latiore folio*, meadow graſs, with a larger panicle, and broader leaf, which is the *poa paniculâ diffuſâ, ſpiculis trifloribus glabris, culmo erecto teretri*, Flor. Suec. 76. Poa with a diffuſed panicle, ſmall ſpikes with three flowers, and an upright ſtraw.

Theſe ſeem to be the great meadow graſſes Mr. Stillingfleet obſerves are common in our beſt meadow grounds. He has alſo met with them frequently on banks by the road ſide, and near ditches, even where they were not to be found in the adjoining meadows and paſtures. But as he has not favoured us with a botanical deſcription of them, we can only form conjectures.

If the ſeeds of theſe two ſorts were carefully collected and ſown ſeparately, without any mixture of the ſeed of other graſs, they would not only afford a greater quantity of fodder on the ſame ſpace of land, but the graſs would alſo be better, the hay ſweeter, and the verdure more laſting, than that of any other ſpecies. Mr. Miller recommends this particularly to every gentleman who would improve the verdure near his habitation.

The annual meadow graſs makes the fineſt of turfs. It grows every where by way ſides, and on rich found commons. It is called in ſome parts the Suffolk graſs, as we mentioned before. Mr. Stillingfleet ſays, he has ſeen whole fields of it in High Suffolk, without any mixture of other graſſes, and as ſome of the beſt ſalt butter we have in London comes from that country, it is moſt likely to be the beſt graſs for the dairy. *See* ANNUAL MEADOW GRASS.

As the next beſt to meadow graſs, Mr. Miller recommends Ray's *gramen avenaceum pratenſe elatius, paniculâ ſtaveſcente, locuſtis parvis*, taller meadow oat-graſs, with a yellowiſh panicle, and ſmall huſks, which is the *avena paniculâ laxâ, calycibus trifloris brevibus, foſculis omnibus ariſtatis*, Prod. Leyd. 66. Oat-graſs with a looſe panicle, three flowers in each empalement, which is ſhort, and all the flowers having awns. Mr. Ray likewiſe recommends the ſmooth mountain oat-graſs, which he calls *gramen avenaceum montanum ſpicâ ſimplici, ariſtis recuroris*, found by Mr. Dale, upon Bartlow hills in Eſſex, on the edge of Cambridgeſhire, in the borders of the corn fields between Newmarket and Exning, and on the chalk hills between Northfleet and Graveſend: and the rough or hairy oat-graſs, which he diſtinguiſhes by the apellation of *gramen avenaceum hirſutum, paniculâ purpuro-argentiâ ſplendente*, and which abounds in the paſtures about the earl of Cardigan's houſe at Twittenham, in Middleſex. He alſo includes under this genus, all the feſtucca kinds, of which Mr. Stillingfleet gives the following account, in his Obſervation on Graſſes, ſubjoined to his tranſlations of ſeveral ingenious tracts, ſelected from the Tranſactions of the Academy of Upſal.

Sheeps feſcue, which he diſtinguiſhes by the name of *feſtuca ovina*, is the graſs moſt eſteemed for the food of ſheep in Sweden, where they have not ſuch downs as we have.

Gmelin ſays, that the Tartars chooſe to fix, during the ſummer, in thoſe places where there is the greateſt plenty of this graſs, becauſe it affords a moſt wholeſome nouriſhment to all kinds of cattle, but chiefly ſheep: and he obſerves, that the ſepulchral monuments of the ancient Tartars are moſtly found in places which abound with this graſs, which ſhews, adds he, that it has long been valued among them.

This graſs abounds in many parts of England and Wales, and particularly on all the fineſt ſheep paſtures in Herefordſhire, Oxfordſhire, Norfolk, &c. Mr. Stillingfleet obſerves, that it is a very early graſs, and that, contrary to what Linnæus ſays, either ſheep or ſome other animals do eat the flowering ſtems of this graſs; for, when he ſearched for it upon Banſtead downs, he could ſee no part of it but the radical leaves, except among buſhes near the hedges, where it was guarded from the ſheep.

Mr.

Mr. Stillingfleet ſays, that he has always ſeen the purple feſcue along with the fine bent and ſilver hair graſs, which will be ſpoken of hereafter, particularly on Banſtead downs, in great plenty, in a place incloſed in order to keep the ſheep out. From thence he is inclined to think, that this is the chief graſs all over the downs; but as the flowering ſtems in the other parts were intirely gone at the time of his viewing it, except along the hedges, he could not be certain in this reſpect.

After candidly declaring his want of knowledge of the qualities of the flote feſcue, which he calls *feſtuca fluitans*, Mr. Stillingfleet quotes a curious paſſage in the Tranſactions of the Academy of Upſal, where the author of a piece entitled *Plantæ Eſculentæ* ſays, that the ſeeds of this graſs are gathered yearly in Poland, and from thence carried into Germany, and ſometimes into Sweden, and ſold under the name of manna ſeeds, and that they are there much uſed at the tables of the great, on account of their nouriſhing quality and agreeable taſte. Mr. Stillingfleet then adds, that one Mr. Dean, a very ſenſible farmer at Ruſcomb, in Berkſhire, aſſured him, "that a field of about four acres, which always lay under water, and was occupied by his father when he was a boy, was covered with a kind of graſs that maintained five farm horſes in good heart, from April to the end of harveſt, without giving them any other kind of food, and that it yielded more than they could eat." Some of it was carried to Mr. Stillingfleet, who found it to be the flote feſcue, with a mixture of the marſh bent: but whether this laſt contributes much towards furniſhing ſo good paſture for horſes, ſeems doubtful to him. They both threw out roots at the joints of the ſtalks, and are therefore likely to grow to a great length.

Linnæus ſays, that the bran of this graſs will cure horſes troubled with bots, if they are kept from drinking for ſome hours.

In the index of dubious plants, at the end of Ray's Synopſis, mention is made of a graſs called *gramen caninum ſupinum longiſſimum*, longeſt ſupine dog's graſs, which grows at Maddington in Wiltſhire, and in ſome parts of Wales, to the length of twenty-four feet, and is uſed for the fattening of hogs. Its ſtalks are of the creeping kind, and touch the ground at ſeveral of their knots; for they do not riſe much in height. Mr. Stillingfleet thinks it the flote feſcue, and rightly adviſes farther inquiries concerning it. But he does not ſeem here to have conſulted Wr. Worlidge, who ſays, ſpeaking of this graſs, that it is extraordinarily ſweet, but not ſo eaſily propagated as hath been imagined, the length thereof being occaſioned by the waſhing of a declining ſheep down, from whence haſty rains bring with them much of the fatneſs of the dung of the ſheep, which ſubſides upon the ſmall meadows where this graſs grows: ſo that in ſprings not ſubject to theſe ſhowers, or on lands not enriched by that fertiliſing ſoil brought down to them, this graſs does not thrive ſo well.

The vernal graſs, which Mr. Stillingfleet calls *anthoxanthum odoratum*, and which is at leaſt a ſpecies of Ray's *gramen vernum ſpicâ brevi laxâ*, and of C. Bauhin's *gramen vernum pratenſe ſpicâ flaveſcente*, vernal graſs, with a looſe yellowiſh ſpike, is one of the earlieſt graſſes, and grows very commonly in all our meadows, paſtures, and other grounds. It is found in plenty upon thoſe paſtures which ſheep are fond of, and from whence excellent mutton comes; and therefore it is moſt likely to be a good graſs for ſheep paſtures. Mr. Stillingfleet ſays, he has found it on all kinds of grounds, from the moſt ſandy and dry to the moſt ſtiff and moiſt, and even in bogs. It is very plentiful in the beſt meadows about London, viz. towards Hampſtead, and Hendon; and its ſeeds may be gathered very eaſily, as it ſheds them upon the leaſt rubbing. This graſs gives a grateful odour to hay.

Mr. Liſle remarks, that the *gramen parvum repens purpureâ ſpicâ*, ſmall creeping graſs, with a purple ſpike, is no indication of bad ground, though it be a very bad graſs. Ray ſays, that it is very common in paſtures. There ſeems to be a great ſweetneſs in it. The ſame may be ſaid of the *gramen criſtatum*, or ſmooth creſted graſs, which alſo abounds every where in our meadows and paſtures.

The meadow fox-tail graſs *(gramen alopecuroides)* abounds in our beſt meadows about London, and makes very good hay; perhaps the beſt of any that is brought to market here. Mr. Stillingfleet obſerved in the ſpring of the year 1762, a meadow near Hampſtead, which conſiſted of this graſs chiefly, with ſome of the vernal graſs and the corn-brome graſs: but it is ſcarce in many parts of England, particularly in Herefordſhire, Berkſhire, and Norfolk; though it might be gathered at almoſt any time of the year, even from hay-ricks, as it does not ſhed its ſeeds without rubbing, which is the caſe of but few graſſes.

The water fox-tail *(alopecuroides paludoſum)* is alſo found in ſuch meadows about London as are ſound and lie under water in the winter. Mr. Stillingfleet thinks it may, perhaps, be a proper graſs to ſow on ſuch grounds.

Mr. Stillingfleet has always found the fine bent-graſs, which he names *agroſtis capillaris*, in great plenty on the beſt ſheep paſtures, as on Malvern-hills, Bagſhot-heath, and all the high grounds in Herefordſhire, Berkſhire, Oxfordſhire, and Norfolk, and other places remarkable for good mutton.

The ſame may be ſaid of the mountain hair-graſs, which he calls *aira flexuoſa*; and of the ſilver hair-graſs, which is his *aira caryophillea*.

The quaking-graſs, cow-quake, or lady's-hair, as it is called in ſome places, is the *gramen tremulum maximum*, of C. Bauhin, and J. Ray, and the *briza ſpiculis cordatis, floſculis ſeptendecim*, Hort. Cliff. 23. Briza with heart-ſhaped little ſpikes, and ſeventeen flowers in each. Though a very poor and ſlender graſs, Mr. Liſle thinks it no indication of poor land where it grows: for, as Mr. Ray obſerves, it is the moſt common graſs of any in all the paſture grounds throughout England.

Mr. Miller deſcribes it as having an annual root, which ſends up many broad hairy leaves, between which ariſe ſlender ſtiff ſtalks, from a foot to near two feet high, dividing upward into a large looſe panicle, garniſhed with heart-ſhaped ſmall ſpikes, each having about ſeventeen ſmall floſcules, or florets; and theſe, after the flowers are paſt, are ſucceeded by a ſingle ſeed. The heads hang by ſlender long foot-ſtalks, which are moved by every wind, ſo that they generally appear ſhaking; from whence it had the name of quaking-graſs. There is a ſmaller ſpecies of it, which is a native of England; but, I believe, of no greater value than the former. Theſe graſſes come to head in May: and this gave riſe to the Engliſh proverb, May, come ſhe early come ſhe late, makes the cow quake.

Matweed *(gramen ſparteum)* is of the broom kind, and delights in ſandy places, near the ſea. Even clouds

of ſand blown over it do not hurt, but, on the contrary, promote its growth. It has been of excellent ſervice in fixing looſe ſands, as, if I have been rightly informed, it once did very remarkably in Norfolk. Of ten ſpecies of this plant, which Mr. Ray diſtinguiſhes, the following are the chief. 1. *Spartium Plinii, ſive juncus Hiſpanicus*, the true matweed of Pliny, or Spaniſh broom; 2. *Gramen ſparteum paniculâ brevi folliculo incluſâ*, hooded matweed; 3. *Gramen ſparteum marinum Anglicanum* Engliſh ſea matweed, or marram; 4. *Spartum maximum maritimum Hollandicum, ſpicâ ſecalinâ*, the greateſt Holland matweed; with a rye ſpike; 5. *Gramen ſparteum pennatum*, Feather-graſs; and 6. the *Gramen ſparteum juncifolium*, or *ſpartum parvum*, ſmall matweed.

Mr. Stillingfleet ſays, that the beſt mutton he ever taſted, next to that which comes from hills, where the purple and ſheep's feſcue, the fine bent, and the ſilver hair graſſes abound, was fed upon the creſted dog-tail graſs, which he and Mr. Hudſon call *cynoſurus criſtatus*. He therefore rightly judges it proper for parks; and confirms this opinion, by adding, that he knows a park where this graſs abounds, which is famous for excellent veniſon. It makes a very fine turf upon dry, ſandy, or chalky ſoils: but unleſs it be ſwept over with the ſcythe, its flowering ſtems will look brown; as is the caſe of all graſſes which are not fed by a variety of animals: for that ſome animals will eat the flowering ſtems, is evident from commons, where one ſcarcely ſees any part of the graſſes, except the radical leaves.

Mr. Miller thinks the cock's-foot graſs (Ray's *Gramen dactylon*, Hiſt. p. 1271) the capon's-tail graſs (Ray's *Gramen murorum ſpicâ longiſſimâ*, Hiſt. p. 1286) and the millet graſſes *(Gramina miliacea)* too coarſe to deſerve attention in England; though ſome of their ſpecies are very uſeful in the warm parts of America, where there is a great ſcarcity of finer graſs, and even much better adapted for ſuch climates, than any of our European graſſes; becauſe many of them lie flat on the ground, and emit roots from their joints, by which means they are well prepared for heat; of which their large and juicy ſtalks likewiſe enable them to bear an extraordinary degree.

The purple, or, as it is commonly called, red meadow trefoil, which is C. Bauhin's *Trifolium pratenſi purpureum*, has already been ſufficiently diſtinguiſhed from the common red clover, or red honeyſuckle (Ray's *Trifolium purpureum majus, pratenſi ſimile, Sym.* 328) which though Mr. Liſle thinks otherwiſe, is undoubtedly a native of England, as is manifeſt from its ſpontaneous and flouriſhing growth on the top of many mountains, particularly in even the moſt northern parts of Scotland, where no mortal ſurely ever dreamt of cultivating it. The ſpecies called yellow meadow trefoil, or hop-clover, is C. Bauhin's *Trifolium pratenſe luteum, capitulo lupuli, vel agrarium*; and the ſmaller kind of this, commonly called noneſuch, or black ſeed, is the *Trifolium luteum, lupulinum, minimum*. M. Duhamel rightly prefers the firſt of theſe ſorts for artificial paſtures, and obſerves, that it is the only ſpecies now cultivated in France, for that purpoſe.

Our meadows afford us the white meadow trefoil, honeyſuckle-graſs, or white Dutch clover, which is the *trifolium pratenſe album* of C. Bauhin, and by far the beſt ſort of clover for laſting paſtures, becauſe it is the ſweeteſt and moſt abiding of all the plants of this kind. *See* CLOVER.

I do not know that the narrow leaved plantain, or ribwort *(Plantago auguſtifolia)* hath ever been cultivated purpoſely for the food of cattle. It grows, indeed, in almoſt all paſtures: but, as it will thrive upon very dry ſpots, becauſe it ſtrikes a deep root, it may probably deſerve farther trial.

The late Dr. Eliot recommends two ſorts of graſſes, natives of North America, of which he lately ſent over a parcel of the ſeeds to the London Society for the Encouragement of Arts, &c. by whom they have been diſtributed here, ſo that we may hope ſoon to know their ſucceſs in this country, and of which he has given an account in his Eſſays upon Field-Huſbandry in New England. *See the articles* BIRD-GRASS, *and* TIMOTHY-GRASS.

GRASS-*Leaſe*, graſs-lands, or lands appropriated to graſs, for feeding of cattle.

GRATTEN, a term uſed in Cornwal, to imply the mowing of graſs, the firſt year after the land has been manured with ſea-ſand; and this operation they call mowing in gratten.

GRAVELLY-*Land*, that which abounds with gravel and ſand. *See the article* SANDY-LAND.

The beſt manure for this ſort of land is marl, or any ſtiff clay that will diſſolve with the froſt, cow-dung, chalk, mud, and half rotten ſtraw from the dunghill.

GREASE, a diſeaſe incident to horſes and other cattle, conſiſting of ſwellings and gourdineſs of the legs.

In order to treat this diſorder with ſome propriety, without having recourſe to the falling down of humours for its explanation, we ſhall conſider it as ariſing from two different cauſes; a fault or relaxation in the veſſels, or a bad diſpoſition of the blood and juices. In order to this, it will be neceſſary to obſerve, that the blood and juices are carried to the extreme parts by the arteries, and returned by the veins; conſequently the blood muſt riſe perpendicularly in the latter, in order to return from the extremities to the heart. And hence ſwellings in the legs of horſes may be eaſily accounted for, as a partial ſtagnation of the blood and juices may be naturally expected where the circulation is languid, eſpecially when there is a want of due exerciſe, and a proper muſcular compreſſion on the veſſels to puſh forward the returning blood, and propel the inert, and half ſtagnating fluids through their veſſels. In ſhort, the blood, in ſuch caſes, cannot ſo eaſily aſcend as deſcend, or a greater quantity will be brought by the arteries than can be returned by the veins.

The greaſe then, conſidered in this light, muſt be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted, and in good condition; or as a diſorder where they are both complicated: but when it is an attendant on ſome other diſtemper, as the farcy, yellow dropſy, &c. ſuch diſeaſes muſt firſt be cured before the greaſe can be removed. In the former caſe, moderate exerciſe, proper dreſſing, cleanlineſs, and external applications, will anſwer the purpoſe; in the latter, internals muſt be called in to our aſſiſtance, with proper evacuations.

When a horſe's heels are firſt obſerved to ſwell in the ſtable, and ſubſide, or go down, on exerciſe, let care be taken to waſh them very clean every time he comes in, with ſoap-ſuds, chamberlye, or vinegar and water, which, with proper rubbing, will frequently prevent or remove this complaint: or let them be well bathed twice a day with old verjuice, or the following mixture, which will brace

up

up the relaxed veſſels; and if rags dipped in the ſame are rowled on, with a proper bandage, for a few days, it is moſt likely the ſwellings will ſoon be removed by this method only, as the bandage will ſupport the veſſels till they have recovered their tone. To anſwer this end alſo, a laced ſtocking, made of ſtrong canvas, or coarſe cloth, neatly fitted to the part, would be found extremely ſerviceable, and might eaſily be contrived by an ingenious mechanic.

Take rectified ſpirit of wine four ounces, diſſolve it in half an ounce of camphor, to which add wine-vinegar, or old verjuice, ſix ounces; white vitriol, diſſolved in a gill of water, one ounce; mix together, and ſhake the phial when uſed.

But if cracks or ſcratches are obſerved, which ouſe and run, let the hair be clipped away, as well to prevent a lodgment (which becomes ſtinking and offenſive by its ſtay) as to give room for waſhing out dirt or gravel, which, if ſuffered to remain there, would greatly aggravate the diſorder.

When this is the caſe, or the heels are full of hard ſcabs, it is neceſſary to begin the cure with poultices, made either of boiled turneps and lard, with a handful of linſeed powdered, or oat-meal and rye-flour, with a little common turpentine, and hogs lard, boiled up with ſtrong beer grounds, or red wine lees. The digeſtive ointment being applied to the ſores for two or three days, with either of theſe pultices over it, will, by ſoftening them, promote a diſcharge, unload the veſſels, and take down the ſwelling, when they may be dried up with the following:

Take white vitriol and burnt alum, of each two ounces; Ægyptiacum one ounce; lime water a quart, or three pints: waſh the ſores with a ſponge dipped in this, three times a day, and apply the common white ointment, ſpread on tow; to an ounce of which may be added two drams of ſugar of lead.

Or the following waſh and ointment may be uſed for that purpoſe.

Take half an ounce of Roman vitriol, diſſolved in a pint of water; then decant off the clear into a quart bottle, add half a pint of camphorated ſpirits of wine, the ſame quantity of vinegar, and two ounces of Ægyptiacum.

Take honey four ounces, white or red lead, powdered, two ounces, verdigreaſe in fine powder one ounce; mix together.

Some, for this purpoſe, apply allum-curd; others a ſtrong ſolution of allum in verjuice, with honey; and many of theſe forms may be eaſily contrived. But let it be remembered, that as ſoon as the ſwelling is abated, and the moiſture leſſened, it would be very proper to keep the legs and paſterns rolled up with a firm bandage, or linen rowler, two or three fingers wide, in order to brace up the relaxed veſſels, till they have recovered their natural tone.

This method is generally very ſucceſsful, when the diſtemper is only local, and requires no internal medicines: but if the horſe be full and groſs, his legs greatly gorged, ſo that the hair ſtares up, and is what ſome term pen-feathered, and has a large ſtinking diſcharge from deep foul ſores, you may expect to meet with great trouble, as theſe diſorders are very obſtinate to remove, being often occaſioned by a poor dropſical ſtate of the blood, or a general bad diſpoſition in the blood and juices.

The cure in this caſe, if the horſe is full and fleſhy, muſt be begun by bleeding, rowels, and repeated purging; after which diuretic medicines are frequently given with ſucceſs. Thus,

Take four ounces of yellow roſin, one of ſal prunellæ; grind them together with an oiled peſtel, add a dram of oil of amber, and give a quart of forge-water every morning, faſting two hours before and after taking, and ride moderately.

As this drink is found very diſagreeable to ſome horſes, I would recommend the nitre balls in its ſtead, given to the quantity of two ounces a day, for a month or ſix weeks, mixed up with honey, or in his feeds: take the following alſo for that purpoſe.

Yellow roſin four ounces, ſalt of tartar, and ſal prunellæ, of each two ounces; Venice ſoap half a pound; oil of juniper half an ounce; make them into balls of two ounce weight, and give one every morning.

Or,

Take nitre two ounces; camphor one dram, honey enough to make into a ball; give as the former.

The legs in this caſe ſhould be bathed or fomented, in order to breath out the ſtagnant juices, or to thin them, ſo that they may be able to circulate freely in the common current. For this purpoſe foment twice a day with a diſcutient fomentation, in which a handful or two of wood aſhes has been boiled; apply then the above poultice, or the following, till the ſwelling has ſubſided, when the ſores may be dreſſed with the green ointment till they are properly digeſted, and then dried up with the water and ointment above recommended.

Take honey one pound, turpentine ſix ounces, incorporate with a ſpoon; and add of the meal of fenugreek and linſeed, each four ounces; boil in three quarts of red wine lees, to the conſiſtence of a poultice; to which add, when taken from the fire, two ounces of camphor in powder; ſpread it on thick cloths, and apply warm to the legs, ſecuring it on with a ſtrong rowler.

If the ſores are very foul, dreſs them with two parts of the wound ointment, and one of Ægyptiacum; and apply the following, ſpread on thick cloths, and rowled on.

Take of black ſoap one pound, honey half a pound, burnt allum four ounces, verdigreaſe powdered, two ounces, wheat flour a ſufficient quantity.

If the diuretic balls ſhould not ſucceed, they muſt be changed for the antimonial and mercurial alteratives, already mentioned; but turning a horſe out in a field, where he has a hovel or ſhed to run to at pleaſure, would greatly

greatly contribute to quicken the cure; and, indeed, would in general effect it alone: but if this cannot be complied with, let him be turned out in the day time.

If the horſe is not turned out, a large and convenient ſtall is abſolutely neceſſary, with good dreſſing and care: this ſtall ſhould be ſix feet wide, that a tall horſe may ſhoot out his legs at length, ſo that the blood may circulate freely, without meeting with reſiſtance, which it naturally muſt, when a horſe lies all on a heap, or with his legs under him: nor ſhould the ſtable be paved with too great a declivity; for if the horſe ſtands too low with his hind legs, moſt of his weight will reſt upon them; and give him the greaſe, eſpecially if he be at all inclined to be gourdy.

The laſt thing we ſhall recommend, is to make him lie down in the ſtable as often as poſſible. This is undoubtedly of the utmoſt conſequence, as it will not a little contribute to the removal and cure of this diſorder; for by only changing the poſition of his legs, a freer circulation would be obtained, and the ſwelling taken down; whereas it is in general greatly aggrivated by the obſtinacy of the horſe, which refuſes to lie down at all, probably from the pain it gives him in bending his legs neceſſary for that purpoſe; by which means the ſtiffneſs and ſwelling increaſes, till the over-gorged and diſtended veſſels are obliged to give way, and, by burſting, diſcharge the fluids that ſhould circulate through them. *Bartlet's Farriery, page* 284.

GREASE melted. *See the article* MOLTEN-GREASE.

GREEN-SCOURING, a diſeaſe to which ſheep and bullócks are often ſubject.

The beſt remedy for this diſorder is verjuice; a wine glaſs full is enough for a ſheep, and a pint for a bullock. *Liſle's Huſbandry, vol.* II. *page* 211.

GRIP, or *Gripe*, a ſmall ditch cut acroſe a meadow or ploughed-field, in order to drain it. It is otherwiſe called a water furrow.

GRIPES, a very acute diſeaſe to which horſes are very often ſubject.

There ſeems to be no diſtemper ſo little underſtood by the common farrier, as the gripes or cholic in horſes, one general remedy, or method, ſerving them in all caſes; but as this diſorder may be produced by very different cauſes, the method of cure muſt alſo vary, otherwiſe the intended remedy, injudiciouſly applied, will not only aggravate the complaint, but make it fatal. We ſhall divide this diſorder into three different ſpecies: the flatulent or windy, the bilious or inflammatory, and the dry gripes; each of which we ſhall diſtinguiſh by their different ſymptoms, and then point out the proper remedies.

The flatulent, or windy cholic is thus known. The horſe is often lying down, and as ſuddenly riſing again with a ſpring; he ſtrikes his belley with his hinder-feet, ſtamps with his fore-feet, and refuſes his meat; when the gripes are violent, he will have convulſive twitches, his eyes be turned up, and his limbs ſtretched out as if dying, his ears and feet being alternately very hot and cold; he falls into profuſe ſweats, and then into cold damps; ſtrives often to ſtale, and turns his head frequently to his flanks; he then falls down, rolls about, and often turns on his back; this laſt ſymptom proceeds from a ſtoppage of urine, that almoſt always attends this ſort of cholic, which may be increaſed by a load of dung preſſing on the neck of the bladder.

Theſe are the general ſmyptoms of cholic and gripes from wind, drinking cold water when hot, and when the perſpirable matter is retained, or thrown on the bowels by catching cold; in all which caſes they are violently diſtended. Cribbing horſes are more particularly ſubject to this complaint, by reaſon they are conſtantly ſucking in great quantities of air.

The firſt intention is to empty the ſtrait gut with a ſmall hand dipt in oil, which frequently makes way for the confined wind to diſcharge itſelf; and by eaſing the neck of the bladder, the ſuppreſſion of urine is taken off, and the horſe ſtales and gets eaſe.

Farriers generally ſtrike a fleam into the bars of a horſe's mouth, which ſeems to be of little or no uſe; for where a quantity of blood is intended to be taken away, the veſſels of this part are neither large or numerous enough to furniſh it; ſo that it is more eligible to take it from the neck-vein, and is always proper in full, ſanguine, plethoric, young horſes.

The following ball and clyſter ſeldom fail of giving relief in theſe caſes:

Take Straſburgh or Venice turpentine, and juniper-berries pounded, of each half an ounce; ſal-prunella, or ſalt-petre, an ounce; oil of juniper, one dram; ſalt of tartar, two drams: make into a ball, with any ſyrup; it may be given whole, and waſhed down with a decoction of juniper-berries, or a horn or two of ale.

If the horſe does not break wind, or ſtale plentifully, he will find no relief; therefore in an hour or two give him another ball, and add to it a dram of ſalt of amber; which may be repeated a third time, if found neceſſary. During the fit the horſe may be walked and trotted gently, but ſhould by no means be harraſſed beyond his ability, or dragged about till he is jaded.

The following clyſter may be given, between the balls, or alone, and repeated occaſionally:

Take camomile flowers two handfuls; aniſe, coriander, and fennel ſeeds, of each an ounce; long pepper half an ounce: boil in three quarts of water to two; and add Daffy's elixir, or gin, half a pint; oil of amber half an ounce, and oil of chamomile eight ounces.

The ſubſequent balls and drink are alſo very proper for this purpoſe, and to remove gripes occaſioned by drinking cold water when hot, or catching cold after violent exerciſe:

Take powder of aniſe, cumin, and fennel ſeeds, of each half an ounce; camphor two drams; pellitory of Spain, one dram; oil of juniper fifty drops, make into a ball with any ſyrup, and waſh it down with a horn or two of ale.

Or,

Take mithridate, or Venice treacle, two ounces; Matthew's pill two drams; camphor one dram, diſſolved in a little ſpirit of wine; powder of freſh anniſeed one ounce; or the ſame quantity of the cordial ball; diſſolve in a pint and half of ale.

Or,

Take philonium one ounce, or an ounce and an half; tincture of ſenna, or Daffy's elixir, and ſallad oil, of

of each half a pint: give warm for a drink, and repeat it if neceſſary.

Either of theſe medicines are well calculated for this purpoſe; but as the ingredients may not always be ready at hand, or procurable, we ſhall put down a couple of drinks that have frequently, on trial, been found ſucceſsful, and are eaſily prepared. It is to be obſerved, that the horſe ſhould be well rubbed, clothed, and littered with clean ſtraw up to his belly.

Take of Caſtile ſoap, or hard ſoap; nitre, or ſalt-petre, of each one ounce; juniper-berries and ginger, each half an ounce: Venice turpentine, or roſin, diſſolved with the yolk of an egg, ſix drams: mix with a pint and a half of warm ale, or a decoction of juniper-berries, with a large onion boiled with them. This may be repeated twice or thrice.

Or,

Take a pint of brandy, rum, or geneva, with as much ſweet oil, and give for a drink. Should this not ſucceed, boil an ounce of pepper or ginger, in a quart of milk; and add to it a handful of ſalt, and half a pint of oil: this given warm, will (according to Burdon) purge in two or three hours.

The ſigns of a horſe's recovery, are his lying quiet, without ſtarting, or tumbling, and his gathering up his legs, and ceaſing to laſh out; and if he continues an hour in this quiet poſture, you may conclude all danger over.

The next ſpecies of cholic we ſhall deſcribe, is the bilious or inflammatory, which, beſides moſt of the preceding ſymptoms, is attended with a fever, great heat, panting, and dryneſs of the mouth; the horſe alſo generally throws out a little looſe dung, with a hot ſcalding water, which when it appears blackiſh, or of a reddiſh colour, and fetid ſmell, denotes an approaching mortification.

In this caſe the horſe ſhould immediately be bled to the quantity of three quarts; and it ſhould be repeated, if the ſymptoms do not abate in a few hours. The emollient clyſter, with two ounces of nitre diſſolved in it, ſhould be thrown up twice a day, to cool the inflamed bowels; plenty of gum arabic water ſhould be taken; and a pint of the following drink given every two or three hours, till ſeveral looſe ſtools are procured; and then it ſhould be given only night and morning, till the diſorder is removed.

Take ſenna three ounces, ſalt of tartar half an ounce; infuſe in a quart of boiling water an hour or two; then ſtrain off, and add two ounces of lenitive electuary, and four of glauber ſalts.

If this diſorder is not removed by theſe means, but the inflammation and fever increaſe, attended with a diſcharge of the fleſh-coloured water above deſcribed, the event will moſt probably be fatal; and the chief thing to be depended on now, muſt be a ſtrong decoction of Jeſuits bark, given to the quantity of a pint every three hours, with a gill of red port wine.

A quart of the ſame may be uſed for a clyſter, with two ounces of Venice turpentine, diſſolved with the yolks of two eggs, an ounce of diaſcordium, and a pint of red wine, and given twice a day: if the horſe recovers, give two or three mild rhubarb purges.

To a horſe of little value, give the following, which, in theſe caſes, has been found ſucceſsful.

Take diapente one ounce, diaſcordium half an ounce, myrrh, in powder, two drams; make it into a ball with two drams of oil of amber, to be given twice or thrice a day.

The laſt we ſhall deſcribe is the dry gripes, or the cholic, which ariſes often from coſtiveneſs: it is diſcovered by the horſe's frequent and fruitleſs motion to dung, the blackneſs and hardneſs of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great reſtleſſneſs and uneaſineſs.

In this caſe the ſtrait gut ſhould be examined and emptied, with a ſmall hand, oiled properly for that purpoſe; the emollient oily clyſter, given under the article *clyſter*, ſhould be thrown up twice a day; and the above purging drink given, till the bowels are unloaded, and the ſymptoms removed.

The diet for a horſe in the gripes ſhould be ſcalded bran, warm water gruel, or white water, made by diſſolving four ounces of gum arabic in a quart of water, and mixing it with this other water.

From this hiſtory and diviſion of gripes and cholics, with their different treatment, it appears how abſolutely neceſſary it is they ſhould be well underſtood, in order to be managed ſkilfully: it is plain, too, that violent hot medicines ſhould, in every ſpecies of this diſorder, be guarded againſt, and given with great caution and diſcretion, even in the firſt kind of flatulent cholic, where indeed they can only be wanted; yet too often, when prepared by the farriers, with oil of turpentine, geneva, pepper, and brine, &c. they even increaſe that diſorder, by ſtimulating the neck of the bladder too forcibly, heating the blood, and inflaming the bowels, till a mortification is brought on them. Theſe are in general the conſtant appearance of horſes that die of this diſorder, whoſe bowels, being examined for that purpoſe, have been found inflamed, full of red and livid ſpots, ſometimes quite black, criſped with extream heat, and rotten.

GRIPS, the ſwaiths, or ſmall heaps of corn, lying in the field, as it is cut down with the ſcythe or ſickle.

GROATS, oats, after the ſhells are taken off.

GROUND, a general name for land, be the ſoil what it will.

The Romans were very attentive to examine the nature of the ground before they broke it up, and diſtinguiſhed it into three ſituations, champaign, hilly, and mountainous. They rightly approved moſt of a champaign country, declining gradually from the foot of a hill toward the ſouth, or ſouth-eaſt; if a hill riſing gently; and if a mountain neither lofty, nor rugged, but covered with plenty of wood and graſs. Either of theſe ſituations is eligible, according to the purpoſe for which the ground is intended; ſome plants affecting hotter, others colder expoſures; ſome delighting to dwell on hills, others in vallies; and ſome again being indifferent to either: but, generally ſpeaking, moſt vegetables chooſe the warm and kindly ſoil of low grounds, fertiliſed by what the rains bring down to them from the hills and more elevated parts.

The ſpontaneous produce of the earth is an infallible indication of the nature and quality of the ground. Wild

thyme

thyme ſhews it to be good for feeding cattle; betony and ſtrawberries direct to wood; camomile points out a mellow ſoil fit for wheat; burnet indicates land fit for paſture; and mallows denote it proper for the uſes of the kitchen-garden, as has been obſerved by lord Bacon, Mr. Evelyn, and others.

On the contrary, ſays the laſt mentioned of theſe writers, ſome ground is ſo cold, as naturally to bring forth nothing but gorſe, broom, holly, yew, juniper, ivy, box, &c. which may perhaps direct us to the planting of pines, firs, and other perennial verdures in ſuch places.

Moſs, ruſhes, wild tanſy, ſedge, flags, fern, yarrow, and withered, blaſted, ſhrubby, and curled plants, are natural indications of a very bad ſoil.

The nature of the ground may alſo be pretty well gueſſed at, by the quality of the water which runs, or is ſtrained through it.

By the ſmells, which, upon the falling of the firſt rains after a long drought, is very pleaſing, and even fragrant, from good and natural mould; but diſagreeable and noxious, if the ground contain any mineral, or other ill quality, as is remarkable in marſhes and fenny places.

By the taſte, all earths, as well as plants, abounding more or leſs in their peculiar ſalts; ſome ſweet and grateful; others bitter, hot, or aſtringent; and others flat and inſipid; eaſily diſcovered by the method which Columella directs, of digging up ſome of the under mould, out of that part of the land which is deemed the worſt, and mixing it thoroughly in an earthen veſſel, with ſweet water, which, when poured off after the groſſer parts have ſubſided, will retain the taſte of the earth ſoaked in it.

The touch will immediately ſhew whether it be ſoft, pliant, fat, and ſlippery; whether it ſticks to the fingers, or melts and diſſolves on the tongue; in which caſe the ſoil may be deemed rich. If it be gritty, light, and porous, it is bad.

Mould fit for the production of plants is of an uniform ſubſtance, unmixed with the contrarieties of ſoft and hard, churliſh and mild, moiſt and dry: neither is it too unctuous or too lean; but light, and crumbles eaſily; yet is conſiſtent enough to be wrought and kneeded. It is of ſuch due tenacity as to retain a juſt degree of moiſture, and neither ſoils the fingers, nor cleaves much to the ſpade, which eaſily enters it. Of this kind is the ſoil uſually found under the turf of paſture-grounds, upon which cattle have been long fed and foddered. In ſhort, that is the beſt mould which is blackeſt, cuts like butter, ſticks not obſtinately, breaks into ſmall bits, ſmells ſweet, is tempered without cruſting or chopping in dry weather, or becoming poachy in wet, which ſhines after the plough, where flocks of crows follow the ploughman, and, as Pliny expreſſes it, peck at his very heels.

As to colour, next to the blackiſh, the pre-eminence is generally given to the darker gray, and after that to the ruſſet: the clear tawny is reputed worſe; the light and dark aſh-colour (light of weight and reſembling aſhes) good for very little: and the yellowiſh red, the worſt of all.

The common opinion, that all hot grounds are red or brown; cold and dry, blackiſh; cold and moiſt, whitiſh; hot, and moiſt, ruddy; is, notwithſtanding the ſpecious arguments alledged in favour of it, from the exhalation of minerals, the heat of the ſun, and other accidents, exploded by Columella, who propoſes, as a much ſurer way to judge of the goodneſs of land, digging a trench, and afterwards throwing back the ſame earth that was dug out, treading it down well when it is returned. If, ſays he, through a kind of ferment as it were, there be more than enough to fill the trench, it is a certain ſign that the ſoil is fat: if there be not enough, we may be ſure that it is poor and lean; and if the quantity be juſt ſufficient to fill the hole from whence it was taken, it is of a middling quality.

Mr. Evelyn, after examining the component parts of ſeveral ſorts of ſoils, concludes, that the very fineſt earths and beſt moulds, however to appearance mixed with divers imperfect bodies, may, for aught we know, conſiſt more of ſandy particles, than of any other whatever. Hence he infers, that earth, ſtript of all heterogeneous particles, retains only weight, and an inſipid ſiccity; and doubts whether it afford any thing more than embracement to the firſt rudiment of plants, protection to the roots, and ſtability to the ſtem; being "unprolific till married to ſomething of a more maſculine virtue, which irradiates her womb: but otherwiſe, nouriſhing only from what is added, without any action or material contribution: for, ſays he, what gives the divers tempers to moulds, ſeems rather to be cauſed by the perpetual and ſucceſſive rotting of vegetable and animal ſubſtances, than by any peculiar and ſeparate principle; the clammineſs of the earth ſeeming rather ſomething extrinſical and accidental to it, than natural and originally conſtitutive. We know indeed, that the earth is, without any artificial auxiliaries, indued with a wonderful prolific virtue: but as this is liable to be loſt, or to decay, and never can be expected from ſome grounds, without helps; it may be worth our while to conſider, by what expedients the deſired effect of perpetuating its vigour may beſt be accompliſhed."

The means of giving and perpetuating this vigour now becomes properly the ſubject of our farther enquiry, conſiſtent with what was obſerved before, that in order to the earth's having this vigour, it ſhould be conſtantly kept in an alkaline or calcarious ſtate. Mr. Evelyn is clearly of this opinion, when he ſays, "I firmly believe that were ſalt-petre to be obtained in plenty, we ſhould need but little other compoſt to meliorate our ground." In other words, could the earth be always kept in a ſtate fit for collecting nitre, it would conſequently be always in a ſtate fit for the production of plants. They who are acquainted with chemical reſearches, know, that nitre is obtained from ſubſtances of a mixed nature. Its baſis is a calcarious earth, to which muſt be added putrid or alkaline ſubſtances, eſpecially of the vegetable kind.

Mr. Evelyn and ſome later writers have ſpoken ſo much of the effects of nitre, and nitrous earths, in vegetation, that many have imagined nitre to be eſſentially neceſſary in the growth of plants: though Dr. Woodward aſſures us, that, by all the trials he has been able to make, the very contrary ſeems to be the caſe; for that nitre, when contiguous to a plant, rather deſtroys than nouriſhes it. When, therefore, they mention nitre, and nitrous earths, it is more than probable that they mean earth in a ſtate fit for collecting nitre: but when the alkaline ſubſtances are once ſaturated by the acid in the air, or when the alkali is brought to a neutral ſalt, as nitre is, its fertile ſtate then ceaſes, and it becomes a hard compact body, much more impervious to the roots of plants than it was before.

The nature of calcarious ſubſtances, and that of the two kinds of alkali, viz. the fixed alkaline ſalt of plants, and

and the volatile alkali ariſing from animal and putrid vegetable ſubſtances, has already been explained.

Farmers commonly ſay, that lime (to which might be added all other calcarious ſubſtances) does not fatten, but only mellows the earth; meaning, according to Dr. Woodward, that it does not contain in itſelf any thing of the ſame nature with the vegetable mould, or, in other words, afford any matter fit for the formation of plants; but that it only ſoftens and relaxes the earth; by that means rendering it more capable of entering into, and of nouriſhing the ſeeds and vegetables ſet in it, than it would otherwiſe be. It is well known how apt lime is to be put into a ferment and commotion by water. Now this commotion can never happen when the lime is mixed with earth (and it retains its qualities of lime) however hard and clodded the ground may be, without opening and looſening it. What Dr. Woodward ſays of ſalt, in general, may more properly be applied to the fixed alkaline ſalt of plants. Every one, ſays he, muſt have obſerved, how apt all ſorts of ſalts are to be wrought upon by moiſture, and how eaſily they melt and run with it. When this happens to thoſe that are in the earth, the clods which they are mixed with, moulder and fall aſunder. The ſame gentleman farther obſerves, that if we would render the earth truly fruitful, it muſt be by the addition of ſuch ſubſtances as former crops have robbed it of, or ſuch as contains in itſelf vegetable matter.

The ſeveral manures which are found beſt to promote this end, are chiefly, either parts of vegetables, or of animals; of animals, ſays the doctor, which either derive their own nouriſhment immediately from vegetables, or from other animals that do ſo, and which, being returned to the earth, ſerve for the formation of other ſimilar bodies. Theſe vegetable and animal ſubſtances, are the matter from whence Mr. Evelyn thinks the earth derives that clammineſs which he takes to be a ſure indication of a rich ſoil.

If the effects of the putrefaction of vegetable or animal ſubſtances, when mixed with, and ſeparated in the earth, be duly attended to, we ſhall find this a very probable opinion. Vegetables, or animals, if expoſed to the air, ſoon putrify and fly off into the air: but when they are divided into ſmall portions, and mixed with the earth, the earth renders the progreſs of their putrefaction ſlower, and intangles the volatile alkaline particles, which would otherwiſe fly off into the air. Theſe are not only ſtrongly attractive of moiſture, but, like the fixed alkali, attract the acid in the air, and effervеſce with it; whence the double advantage of a moiſt and looſe ſoil.

If we attend to the infinite number of animals and vegetables which are rendered volatile by putrefaction, and fly off into the air; and to the quantity of perſpirable matter from animals and vegetables ſent into the air; and alſo to the effects of the acid found every where in the air on ſuch ſubſtances mixed with the earth; we need no longer wonder at the efficacy which writers, in all ages, have aſcribed to the air, with regard to its quality of enriching the earth.

That the peculiar richneſs of ſoils is owing to the putrid or rotten particles mixed with them, is an opinion of long ſtanding. This is Virgil's *putre ſolem*, rotten, crumbling, or looſe earth; and that which Columella diſtinguiſhes by the appellation of *pinguis et putris*, fat and rotten, or fat, looſe, and crumbling, as the ſoil which yields the greateſt profit with the leaſt labour and expence, becauſe it is naturally neareſt that ſtate which cultivation is intended to effect; "for to cultivate is no other thing but to open, looſen, and ferment the earth."

From theſe principles it is that we account for the appearances before-mentioned of good ſoils, ſuch as, their blackiſh or dark colour (which is that of all ſoils in a putrid ſtate) their ready crumbling, eaſy mouldering, fragrance of ſmell, &c.

Mr. Evelyn conſtantly imputes the fruitfulneſs of the earth to a nitrous ſalt: but if theſe rich putrid ſubſtances are ſubſtituted inſtead of that ſalt (and it ſeems highly probable that he means them) we ſhall find that his reaſoning will appear full as ſtrong, more intelligible, and indeed more rational. The ſubſtance of *p.* 312, and 313, of his Philoſophical Diſcourſe of earth, ſo far as relates to this matter, will run thus:

"It is this putrid quality which entices roots to effect the ſurface of the earth, upon which the fertiliſing rains and dews deſcend; which makes all covered and long ſhaded earth, abound in fertility; which reſuſcitates the dead and mortified earth, when languiſhing and ſpent by our indulgence to her verdant offſpring; her vigour being quite exhauſted, till the rains and ſhowers gently melt into her boſom what we adminiſter to ſupply that which has been conſumed. It is this which fertiliſes and renders Egypt ſo luxuriantly fruitful after the inundations of the Nile, &c."

GROUND-IVY, the name of a trailing plant, which ſtrikes out roots from the joints of its ſtalks: but as it generally grows under hedges, and upon the ſides of banks, it cannot be of any great diſadvantage to the ſoil.

GRUB, the name of a large maggot, produced from the eggs of a certain ſpecies of butterfly. It is of a large ſize, and often does great injury to the corn by undermining it, and preying on its roots. It produces the beetle, and is by ſome called the rook-worm, becauſe rooks are particularly fond of it. The beſt way of deſtroying the grub, is good and frequent ploughings, which will clear the ground however infeſted with this inſect, for ſome years at leaſt.

GRUBBING, the clearing of lands from the roots and ſtumps of trees, buſhes, &c.

Mr. Worlidge rightly obſerves, that the beſt and cheapeſt method of grubbing up thorny ſhrubs, broom, graſs, &c. is ingeniouſly delivered by Gabriel Platt. The inſtrument he has recommended for this purpoſe reſembles a three-grained dung-fork, but much larger and ſtronger, according to the bigneſs of the ſhrubs, &c. the ſtale thereof reſembling a large and ſtrong lever. This inſtrument being placed about half a foot, or any other reaſonable diſtance from the root of the ſhrub, &c. and driven to a good depth, with a ſtrong hedging beetle, then raiſed by laying under it a ſtone or log of wood, is pulled down by means of a rope faſtened to the upper end of the ſtale, and the whole buſh wrenched up by the roots.

GUTTERING-*Plough*, a ſmall and ſimple inſtrument uſed in ſome counties for draining wet lands.

It is ſmall, and worked by a ſingle man. A trench four or five inches broad, and ſix or eight deep, may be eaſily made with it; and on that account it is much uſed for making drains in bleaching grounds, and may do very well for wet clay meadow-land, where the ſoil is ſhallow, and apt to produce a large quantity of ruſhes.

It conſiſts of a piece of iron about five inches broad

and pointed at the end. Upon this piece two other pieces are fixed perpendicular to the former, one on each ſide, the fore-edges inclining backward; ſo that the three edges of the inſtrument form a capital A. To the bottom plate is fixed a ſocket, for receiving the ſtale, which is ſet higher or lower by means of a wedge on the under ſide. At the end of the ſtale is a croſs piece three feet long, againſt which the man's breaſt is placed when he ſhoves the inſtrument before him, in order to cut the drain. A rib twenty-four inches long is fixed on the ſocket, and at the end of it a peg about a foot long, and two inches diameter is faſtened to the ſide of the ſtale with ſcrews. This peg reſteth on the land, when the clod is turned out of the mouth of the inſtrument.

H.

HACK, a pick-axe, or mattock, having only one, and that a broad end.

HARE, a miſt.

HARROW, an inſtrument for breaking the clods of earth, and covering the corn when ſown. It is a ſort of wooden drag, made in the form of a ſquare, with large iron-teeth or tines. The reader will find different ſorts of harrows deſcribed under the articles BEANS, LUCERNE, &c.

HART-CLOVER, melilot.

HARVEST, the ſeaſon when the corn is ripe, cut down, and carried into barns, &c.

Wheat which is full of weeds ought to be cut three or four days ſooner than ordinary, that the weeds may have time to wither before the corn become too ripe: for if it be not cut till the grains are full ripe, it will be liable to conſiderable damage by ſhedding, loſs of colour, and injuries from rain, whilſt it remains expoſed for the weeds to dry. A ſingle ſhower, indeed, or even a day's gentle rain, whilſt it lies in ſwarth, is thought to be rather beneficial to the grain, by making it feel dry and ſlippery, and threſh the better: but all poſſible care ſhould be taken to guard againſt its being wetted too much. When, through any unavoidable accident, it is laid up not thoroughly dry, though it will not take much harm in the mow, it will ſweat and cling together when laid in a heap after being threſhed, and look as white, with mouldineſs, as if it had been ſtrewed with flour. Such corn will not keep, and therefore ſhould be ſent to market, and ſold, as ſoon as it is threſhed.

In Oxfordſhire, and ſeveral other countries, they bind up their wheat in ſheaves, though it be full of weeds, and ſet three ſheaves ſomewhat ſloping againſt three others, after which they cover their tops with two ſheaves opened at their ear ends, which are extended and placed downward. In this ſituation they let their wheat ſtand three weeks or a month in the field, before they carry it in: for no wet can hurt it, nor is it apt to grow in the ear, when thus ſheltered.

In their wheat-pooks, as they call them, in Wiltſhire, the ſheaves are ſet in a circle, with their ears uppermoſt, and another circle of ſheaves is placed upon that, and ſo on, contracting each round, till the pile ends in a point, upon which a ſheaf opened, and turned with the ears downward, is placed, like the ſhackle of a hive; for an ear turned downward will not grow, though ever ſo much wet fall upon it, and the bottom of a ſheaf being broader than its top, every upper one ſhelves over the under, like the eaves of a houſe. A load, or two loads, may be thus put into a pook, which is a very good way to ſecure corn againſt rain, and to give the weeds among it time to dry. But, as Mr. Liſle rightly judges, this method is not altogether proper when the wheat is intended to be laid up in a rick; becauſe, if the weather prove wet, mice will run to it for ſhelter, and will be carried in with the pooks. It is the general way of making wheat-ricks in the iſle of Wight, without thatching.

Though moſt corn is bettered by lying awhile in ſwarth, or grips, to take the dews, which contribute to render its grain plump and of a good colour; yet its ſtraw becomes thereby the worſe for fodder, unleſs it was cut before it had attained full maturity, and lies out no longer than till it be ſufficiently ripened.

In hot dry ſummers, when the corn ripens fully, and its own vigour gives it a proper colour, and plumps up the grain ſo that the huſks readily yield their contents when threſhed, wheat need not lie out in grip, before it is ſheaved, or in ſheaf; unleſs it be very full of graſs and weeds: but in cold ſummers, the wheat is horny and pale, the grains are thin and require being plumped, and their huſks cling ſo cloſe, that they muſt be mellowed, in order to make them threſh well. The full grain which ſwells the chaff, even till it opens, in good and fruitful years, lies almoſt bare to every moiſture; and the heavy ears then ſpread and hang over the ſheaf, which of courſe opens wider, and lets the rain into the bands ſooner than in leſs kindly ſeaſons, when, the wheat being light, the ears in the ſhock ſtand more upright and cloſer together.

In

In proportion to the heat of the weather, greater expedition is neceſſary in reaping; for corn, when haſtily ripened, ſcorched up by the ſun, and full in grain, ſoon takes a ſtain, is damaged by wet, and eaſily ſheds at every blaſt of wind. The prudent huſbandman ſhould therefore, in ſuch caſes, employ the greater number of reapers; for he cannot deſire more, than that his corn be perfectly ripe, and of a good colour; for which reaſon, the leſs it then lies abroad in grip or ſheaf, the better it will be. Cutting it high up, ſo as to avoid the intermixed graſs as much as poſſible, by which means it is the ſooner fit for carting, has been found very ſerviceable on theſe occaſions; and Mr. Liſle is of opinion that, eſpecially in hilly countries, corn can never be better houſed, if thorough ripe, hard, and not weedy, than by gripping and carting as faſt as it is cut down; becauſe the dampneſs which it takes by lying on the ground all night, is not eaſily removed.

It is always moſt adviſable to turn the grips of wheat which is left out, very early after their being cut down, in order to get them dry as ſoon as poſſible. By this means they are kept the longer from ſprouting in the ear, in caſe of rain: for if dripping weather or driving miſt ſhould enſue, and continue for any time, after they have been already loaded with wet, all the art of man cannot prevent their growing: nay, even independent of other accidents, the bare weight of the ears will ſink the grips of wheat to the ground, though they have been laid ever ſo light and hollow; and they will certainly be injured thereby, if ſuffered to lie long out in wet weather. The beſt method of guarding againſt this, is by laying them in triangles, as directed by M. de Lille.

A principle ſomewhat ſimilar to this ſeems to be the reaſon why the farmers in Liceſterſhire, and Northamptonſhire, in particular, where the land is rich, deep, lies flat, and is much incloſed, leave a very high wheat ſtubble, upon which the grips are ſupported, lie the hollower from the ground, and conſequently are the eaſier dried by the ſun and wind; for it is to be obſerved, that the fatter and richer the ſoil is, the ſooner the grips will grow after they have taken wet, if they lie upon the naked ground; much ſooner than they would, in the ſame caſe, in a hilly country, where the land is poor. Huſbandmen there, beſides eſteeming it an advantage that they can ſtow a greater number of ſhort-cut ſheaves in their barns, think the loſs of the ſtraw compenſated by the excellent thatch which they make of the ſtubble. In ſome places they mow it for drying malt.

The forwarder the harveſt is, and the warmer the ſeaſon, the longer the corn may ſafely lay in the field, either in grips, or ſheaves: for this expoſure to the air, after it is cut down, mellows it, and makes it threſh better and look finer. Thus, when the wheat harveſt takes place by the middle, or at leaſt before the latter end of July, of which we have had inſtances, there can be little danger in letting the wheat lie abroad four or five days or a week, if it be not over ripe when cut, even though a rainy day or two ſhould come: for at that time of the year the ſun is ſo hot, the days are ſo long, the graſs ſo ſhort, and the dews generally ſo little, that the corn ſoon dries, even after a hard ſhower; whereas in the middle, and ſtill more toward the latter end of Auguſt, the rainy ſeaſon frequently begins, the dewy nights grow ſo long, the graſs is ſo rough, and the ſun's drying power ſo much abated, that, if wet weather comes on then, the corn will be much more apt to grow.

A caution which Mr. Liſle recommends as ſingularly important in hilly countries, is, not to bind the grips of wheat up into ſheaves too early in the day; becauſe, in ſuch a ſituation, the grips take ſo great a damp by having laid on the ground, that, though the ſtraw, and chaffy ears may ſeem to be dry when the dew is firſt gone off, and after the ſun may have ſhone an hour or two upon them, yet there will remain an inward dampneſs in the corn, and within the ſtraw, which, if laid up in that condition, will come damp from the rick or barn at threſhing time. The afternoon is therefore certainly beſt for gripping and binding into ſheaves in ſuch countries, but ſo that this work may be finiſhed before the day is over. The bands ſhould, however, be laid in the morning, that they may not crack; for the ſtraw will not twiſt after the ſun is up, but will be brittle, and break off below the ears. The turning of three or four of the ſtubble or bottom ends of the ſtraw to the ears of the band, helps greatly to add to its ſtrength and toughneſs.

The bands for binding up the ſheaves ſhould not be ſpread but in fair weather, becauſe, being preſſed down by the grip or two which it is neceſſary to lay upon them to keep them in their places and prevent their being untwiſted by the ſun, they will grow ſooner than any other corn, if rain ſhould come; for they cannot dry, on account of their lying undermoſt. But though the bands muſt always be made while the morning dew is upon them, the ſheaves ought not by any means to be bound up wet: if they are, they will certainly grow mouldy.

Farmers do not always attend ſufficiently to the binding up of their ſheaves, but ſuffer the reapers, for diſpatch, to tie the bands juſt underneath the ears, inſtead of binding them at the other end; the conſequence of which is, that they will hardly hold together to be flung into the cart at harveſt, and will certainly be in great danger of falling to pieces before they are threſhed.

If a little rain is foreſeen in harveſt time, it is beſt to bind the grips up into ſheaves as faſt as they are made; becauſe ſmall ſhowers will wet the ſingle grips ſo much that they cannot be bound up, and thoſe ſhowers may be the fore-runners of greater rains. The ſheaves, being bound, will ſoon dry after ſuch wet. But if a hard rain is foreſeen, the beſt way is not to bind up into ſheaves, becauſe they will then be wet to the bands, and muſt all be opened again. One of Mr. Liſle's neighbours, to whom this happened, unſheafed ſome of his wheat to dry it, opened it, and turned it ſo often, that the ears broke off, by which he loſt half his corn. Caution ought therefore to be uſed in this caſe, leſt by curing one evil we create a worſe.

All farmers agree, that rain which comes with a driving wind, is the worſt of any weather for ſheaves of wheat out in the field; and that it is worſe than a downright ſoaking rain for ſuch ſheaves as are wet to the bands.

In a wet harveſt, ſmall ſheaves are beſt, becauſe, thin at top, and falling cloſe, the rain does not ſink down into the middle of them, and ſo go through into the bands, as it is apt to do in great ſheaves, which lie broader, and take a larger compaſs. Small ſheaves are alſo beſt, when many weeds are intermixed with the corn, becauſe the air, wind, and ſun, have then a greater power to dry them, than they could have if the ſheaves were large.

It has been the opinion of ſome good farmers, that if the weather be likely to continue fair, it is beſt to lay

the ſheaves, the night after the wheat is cut, one by one, flat on the ground, in order to make their ſtraw lie the cloſer together, and their ears ſtand the ſtiffer, and more upright, by which means they will be leſs apt to open at the top, and rain will have the leſs power to penetrate them when laid in ſhocks.

Reapers ſhould take care, in placing their grips, to lay the ſtraw end in the furrow, and the ears out, becauſe theſe will then ſtand ſloping up, and lie tolerably dry, even though rain ſhould come; but in the other way, they would ſoon grow.

Mr. Liſle remarks, in his Obſervations (which might have been thrown into a more regular, as well as more laconic form, before they were publiſhed; for that gentleman certainly never intended, that his unconnected notes and memorandums ſhould appear in the manner in which he penned them merely for his own uſe) that "one of his reapers, when he had made up ſome wheat into ſheaves, the wheat being long-eared and lop-heavy, ſaid, rain had not need meet with thoſe ſheaves before they were carried home." Mr. Liſle aſked him, "Why ſo?" To which the other replied, "becauſe the ears being long and heavy, were buſsle-headed, that is, did hang their heads downward into the ſheaf, ſo that (in caſe a rain ſhould run down to the bands) neither ſun nor wind could enter in to dry them; whereas, ſaid he, when the ears are ſhort, and not heavy, they ſtand upright and hollow, ſo that the ſun and air may eaſily dry them."

The ſtraw of blighted wheat, being hollow and ſpungy, is very apt to imbibe moiſture; for which reaſon the beſt way is to houſe ſuch corn as ſoon as it is tolerably dry, eſpecially if there be the leaſt proſpect of rain; for if ſtraw of that looſe texture ſhould once ſoak in wet, and ſhowery weather ſhould afterward come on, it would require much more time than other corn to dry and fit it for threſhing.

Experience has ſhewn, that wheat keeps better when ſtacked in the ear unthreſhed, than its grain does alone, when threſhed out and laid up in granaries: beſides which, a farther advantage which attends the ſtacking of this corn, is, that the huſbandman need not threſh it but as his markets or other occaſions require; whereas, if it were to remain long in the barn, he would not be able to preſerve it from rats, mice, and other vermin, which harbour in the walls, roofs, &c. of ſuch buildings.

To guard againſt theſe enemies, as well as againſt the dampneſs of the ground, which would otherwiſe occaſion great loſs (for there have been inſtances of its rotting piles of corn to the thickneſs of a yard, or more) four, ſix, or more ſtrong poſts, according to the intended ſize of the ſtack, are driven into the ground, beams of a proper ſtrength are laid acroſs them, and upon theſe is made a floor to ſupport the ſtack. Some farmers build theſe platforms for their ſtacks ſo high from the ground, that there is room to ſhelter their carts and other implements of huſbandry under them: and ſome again, as an additional ſecurity againſt rain and birds, erect ſides and a roof, by which means they form a kind of barn: but this is needleſs, if the corn be ſtacked, as it ought to be, in ſheaves, with the ears turned inward, and the ſtraw ends outward, and the top well thatched with good wheat ſtraw, which is the beſt of any for thatching. They likewiſe cover the ſupporting poſts with tin, for about a foot in breadth from the top, to prevent the mice and rats getting up: but this method ſoon proves ineffectual, becauſe tin is very apt to ruſt, and conſequently loſes its ſmoothneſs. A better way, as Mr. Mortimer adviſes, is to cover thoſe poſts with Dutch tiles, ſuch as chimnies are commonly ſet with, becauſe they will always keep ſmooth. Others make their ſupporters of two hewn ſtones, one of which, being about three feet high, and ſloped from the bottom, where it is two feet wide, to the top, where it is but a foot thick, ſtands upright, and is covered with a large flat ſtone, about a yard ſquare, or, which is better, of a round form. This not only prevents rats and mice from climbing up, but is alſo a ſecurity againſt the dampneſs of the ground. Others again, whoſe method is the beſt of all, lay a foundation of brick as wide as the ſtack is intended to be, and build round it a brick wall, about two feet high, capped with hewn ſtones, which project ſufficiently outward, to hinder the aſcent of any ſort of vermin. If either rats or mice ſhould, by the help of any thing accidentally reſted againſt the ſtack, chance to climb up, and get into the corn, they will not be able to remain there long, becauſe, as they cannot live without water, neceſſity will force them down, and their former means of climbing being removed, they cannot get up again. If any of them chance then to be left in the ſtack, they will ſoon die there for want of drink.

Particular care ſhould be taken in the ſtacking of wheat, always to lay the ear ends of the ſheaves inward, and upon a riſe, ſo as to keep the middle of the ſtack full while it is worked up: for in this caſe, when it ſettles, the ſinking will be chiefly on the outſide, which will thereby be made to lie the cloſer, and the ſtraw ends being outward, and inclining downward, birds cannot get at the grain, nor can rain be driven up to the ears. The ſhorteſt and thinneſt ſheaves ſhould be uſed in the topping of the ſtack, becauſe it cannot be ſo conveniently drawn in and narrowed with great long ſheaves. They ſhould be taken from off the ſame ground, if the huſbandman wants to keep any particular ſort or growth of corn pure and unmixed. Where leſs nicety is obſerved, oats, or ſome other kind of coarſe giain, are frequently laid on the top of the ſtack of wheat under the thatch, the better to preſerve it from being wet. Wheat, properly ſtacked, will keep in perfect order for many years.

Mr. Liſle, who does not approve of ſtacking any corn but wheat, when room can be found for it in the barn, thatched a long rick of vetches, brought up ſharp, with barley ſtraw, to the thickneſs of three feet, and yet found, upon cutting it, that the rain had penetrated through this thick covering, and done conſiderable damage to the vetches. He imputes this, firſt, to barley-ſtraw's being more woolly and ſpungy than wheat ſtraw, which is cloſe and hard; and, ſecondly, to the ſtack's having ſweated and heated pretty much, in which caſe the covering of ſtraw is always hollowed and ſoftened, and conſequently rendered the more apt to admit and retain wet.

The ſtalks of oats are naturally ſo ſmooth and ſlippery, that they are apt to ſlide in the ſtack, which then frequently tumbles down, eſpecially if this corn was very dry when carried in. An oat rick muſt therefore not be widened by any means beyond its foundation, which generally is of faggots, nor ſhould its ſides ever bulge out, but, on the contrary, they ſhould be gradually contracted.

tracted. Barley, having a rough ſtem, may be piled more upright.

When ſparrows rooſt at night in holes, under the eaves of a ſtack of corn, it is reckoned a ſure ſign that there are neither rats nor mice in the rick; for their ſqueaking and running about in the night, would diſturb the birds, ſo that they would not ſtay there.

HASK, a huſky cough.

HATTOCK, a ſtock of corn, conſiſting of twelve ſheaves.

In ſome countries it implies only three ſheaves laid together.

HAVER, a name given to oats in ſome parts of England.

HAW, a cloſe, or ſmall field.

HAW, is alſo the common name for the fruit of the white thorn.

HAW, likewiſe ſignifies a ſwelling of a ſpongy texture, growing in the inner corner of the eye of a horſe, and ſometimes ſo large, as to cover a part of the eye.

HAY, a general name for any kind of graſs, cut and dried for the food of cattle.

When graſs is to be made into hay, the farmer will be directed in the ſeaſon for mowing it, by the quality of the graſs. When the crop is very great, it ſhould be cut as ſoon as the bottom of the graſs grows yellow: for if it ſtands longer, more will be loſt by the quantity of leaves rotted at the bottom, and the ill flavour which theſe will give to the reſt, than will be gained by its growth. When other circumſtances permit the choice of time, it ſhould be when the graſs is in full bloom, before the ſtalks begin to harden, and rather early than late, becauſe the more ſap remains in the roots, the ſooner the next crop will ſpring up. There is not, however, any general rule for this; becauſe, in ſome caſes, the ripe ſeeds add a great value to the hay, as in ſaintfoin and burnet; and, in others, the growth of the graſs itſelf brings a recompence, as in the fowl-meadow graſs.

A dewy or duſky morning ſhould be choſen for cutting the graſs, becauſe, being then fulleſt of ſap, it ſtands beſt to the ſcythe. When the high noon-tide ſun has dried the graſs, and made it recline its head, the mower will employ his time more uſefully in making the hay already cut, than in continuing to mow, with great additional labour, graſs, which no longer makes the due reſiſtance.

Our farmers in general are very inattentive to the management of their hay whilſt in the cock, to which is in a great meaſure owing the loſs which they (or rather the nation) ſuſtain every year, by the damage which the hay receives from rain.

To guard as much as poſſible againſt this accident, let the hay-makers follow the mowers, and, if the weather be quite fine, ſpread out the graſs as faſt as it is cut down, eſpecially if it lie ſo thick in the ſwarth, that neither the air nor ſun can paſs freely through it: but if wet be feared, let it remain in the ſwarth. At night, make it into graſs cocks, and the next day, as ſoon as the dew is off the ground, ſpread it again, and turn it, that it may wither on the other ſide; then handle it, and if you find it dry, make it up into large cocks. If the weather continue favourable during the ſecond day, the graſs will, by that time, be ſo dry as to bear being kept in theſe cocks till the day on which it is to be carted, when it ſhould be ſpread out again in the morning, to receive a farther drying, if wanted. If theſe cocks are made as tall and as taper as can be, conſiſting with their ſtanding ſafely, the winds, by paſſing through them, will dry them gently and equally; and though rain ſhould fall upon them, it will not do much hurt, becauſe the greateſt part of it will run off directly, and the ſun and wind will ſoon dry that which may have penetrated into the cocks. Theſe cocks have therefore a great advantage over the common ſmall and low ones: for if a rainy ſeaſon comes on, theſe laſt will be ſo thoroughly wetted, that the wind will not be able to pierce ſufficiently to dry them. More hay is, perhaps, loſt for want of making the cocks properly, than by all the rains which happen in the hay-making ſeaſon.

The method here recommended is confirmed by the experience of a New England huſbandman, whoſe account of it to the reverend Dr. Elliot run thus:

"I ſhall relate to you my own practice in making of hay, though it may ſeem ſmall and trifling at the firſt mentioning: but finding that it ſaves me near two fifths of the time and labour I uſed to be at in this article, and that my hay is, I think, better than when I uſed to purſue the uſual method, I eſteem myſelf juſtified in communicating it to the public. My method is this: I mow my graſs, and let it lie in the ſwarth till the dew is off the next morning: then I turn and ſpread my hay, and let it lie in the ſun till the after part of the day, when I take it up and cock it well, and never meddle more with it, till I cart it into my barn, or ſtack it. If the weather be good, it will do well to cart after it has ſtood two days in cock. This, I have found by five or ſix years conſtant experience, anſwers for any ſort of hay, except ſalt-hay and red clover, of which laſt I have not had ſo long trial but with reſpect to clover hay, I managed it laſt ſummer after this manner, viz. I followed my mowers, as they cut the graſs, I ſpread it as thin as I could, and before night I put it in cock. The next day, after the dew was off, I ſpread it again; in the afternoon, I cocked it a ſecond time, and meddled no more with it till I carried it. The appearance of the hay ſince, makes me judge that no man has better of the ſort. My firſt coming into this practice was purely accidental. After cutting my graſs, five or ſix years ago, I put it in cock the next day: but my avocations then were ſuch, that I had no time in which I could poſſibly take any farther care of my hay for many days. When I had diſpatched my other affairs, I returned to it, and found it in as good order (that is to ſay the bulk of it) as ever I had hay in my life. Reflecting then, how much labour may be ſaved by this method, I have followed the ſame practice ever ſince, and find it anſwer very well. The reaſon why I think my hay really better is, becauſe I take it for granted, that the more juice or natural moiſture we can retain in it, without corrupting and rotting the ſtalk; the richer and more nouriſhing it is. The too often turning and ſpreading of hay in the ſun extracts too much of the richneſs thereof; and one day's thus lying will take away ſuch a quantity of the moſt watery particles, as that the remainder is only ſufficient to raiſe a proper fermentation thereof when in the cock, while the ſmallneſs of the body there keeps that fermentation from riſing to ſuch a height as to corrupt it. After twenty-four hours, the fermentation will gradually abate: and the pitching of the hay into the cart, and afterwards into the mow, or ſtack, ſo checks it, that it will not again riſe to ſuch a height as to be detrimental. Cattle are fonder of this hay, than of

that

that which is made in the common way, and leſs of it will ſupport them."

It would be almoſt needleſs to obſerve, that no narrow wheels ſhould ever be brought upon paſtures, not even in the drieſt ſeaſon of the year, as that of hay-making generally is. The advantages of broad wheels, which help to roll and level the ground, and render the draught much eaſier, whether on graſs, or any other ſoil in which narrow wheels will ſink, have been confirmed by experience; and are as ſelf-evident, as it is that the latter cruſh and bury, and thereby deſtroy great numbers of the plants of graſs, wherever they are dragged.

If the hay has ſweated a little in the cock, there will be the leſs need for its ſweating afterwards in the rick, where it will then lie ſo much the cloſer, and conſequently keep the better.

For the method of making lucerne and ſaintfoin, *ſee the articles* LUCERNE *and* SAINTFOIN.

HAY-BOTE, a liberty which a tenant for life, or a term of years, has of taking buſhes, wood, &c. for repairing fences, gates, and the like. It alſo ſignifies the liberty of cutting wood, for making rakes and forks uſed in making hay.

HAYN, or *Hayn-up*, implies the action of incloſing with a hedge, in order to preſerve graſs-grounds from cattle.

HAZLE-*Mould*, a moderately compact earth, containing a large quantity of reſin-coloured ſand.

HEAD-LAND, the land running acroſs the others at the head of the field, left for the turning of the plough.

HECK, a door; alſo a rack for cattle to feed at.

HECKLE, an inſtrument uſed in the dreſſing of flax and hemp. *See the articles* FLAX *and* HEMP.

HEDGE. *See* FENCE.

HEIRS, young trees in coppices.

HEE-GRASS, ſtubble of graſs.

HELM, a hovel; alſo ſtraw prepared for thatching.

HEMP, the name of a plant too well known to need any deſcription here; but it may not be improper to remark, that the flowers and the fruit (commonly called ſeeds) of hemp always grow ſeparately on different ſtems, and conſequently on different plants, as this never has more than one ſtem proceeding from the root.

The flower-bearing ſpecies, which is the *Cannabis floriſera*, Off. *Cannabis erratica*, C. B. P. *Cannabis fœmina*, J. B. *Cannabis ſterilis*, Dod. Pempt. and which is moſt frequently termed female hemp, ſhould properly be called barren hemp, flowering hemp, or male hemp, ſince it is this which bears the *farina fecundans*, or fecundating duſt, without being impregnated with which the ſeeds that grow on the other ſtems of the other ſpecies would not come to maturity, or at leaſt would not be capable of producing plants, when ſown.

This other ſpecies, which bears the ſeeds, and which botaniſts diſtinguiſh by the appellation of *Cannabis fructiſera*, Off. *Cannabis ſativa*, C. B. P. *Cannabis mas*, J. B. *Cannabis fœcunda*, Dod. Pempt. and which is commonly termed male hemp, ſhould be called ſeed-bearing hemp, or female hemp; becauſe it is this which, with the help of the impregnation it receives from the *farina fecundans* of the male, produces ſeeds capable of yielding plants of either ſpecies.

What may chance to be the future proportion between the number of male plants, and that of female, in a hemp-ground, cannot poſſibly be gueſſed at the time of ſowing, as no ſort of mark can be diſcerned on the ſeed, by which they may be diſtinguiſhed: nor indeed can any judgment be formed in this reſpect, before the male plants begin to flower, that is to ſay, in general, till about two months after ſowing: unleſs it be from a remark which the moſt curious obſervers have made, that the male hemp is ſlenderer than the female, and that all its parts are more delicate: to which may be added, that the male plant is always forwardeſt in its growth, and that it generally riſes about half a foot higher than the female; thereby plainly indicating it to be the deſign of nature, that the fecundating duſt which iſſues from the flower may by that means be the more eaſily conveyed to the grain on the ſeed-bearing ſtalks, in order to its impregnating that ſeed.

With regard to the temperature of the air that is fitteſt for the growth of hemp, M. du. Hamel obſerves, in his Treatiſe on Cordage, that this plant does not like hot countries; that temperate climates ſuit it beſt; and that it thrives very well in pretty cold regions, ſuch as Livonia and Canada, which produce it in abundance, and very good. M. Marcandier is indeed of opinion, that though extremely hot countries are not favourable to its growth, yet, as this plant is but a ſhort time in the ground, it may be cultivated in any place that is habitable by men.

The wiſe legiſlature of this country has ſhewn its opinion of the importance of raiſing hemp in our own dominions, by the bounty given by parliament for the importation of it from North America; and our truly laudable Society for the Encouragement of Arts, Manufactures, and Commerce, has likewiſe judiciouſly contributed to this deſirable end, by offering a very conſiderable premium to the cultivators of hemp in that vaſt province of the Britiſh empire.

The ſoil for hemp ſhould be a ſoft rich loam, eaſily brought into fine tilth; and it ſhould be well manured. Newly broken up land is found to be peculiarly good for this plant; but flat grounds lying on the ſides of rivers, and enriched by the ſediment left on them when the waters overflow, are the beſt of all for it. If hemp is to be ſown on very ſtrong ſoils, they muſt be brought into ſo good tilth, and be ſo well manured, that their mould may remain looſe: in this caſe, ſuch ſoils yield very great crops. Dry lands are not fit for hemp: it does not riſe well in them, but remain ſhort and ſtinted in its growth, and its fibres are then generally too woody, which renders them hard. All theſe are conſiderable defects, even for the coarſeſt works. It is however true, that, in rainy years, it ſucceeds better on dry grounds, than on moiſt: but as ſuch years are not the moſt common, the beſt ſituation for a hemp-ground is generally thought to be along the ſide of a ſtream, or of a ditch ſo full of water, as that the water may conſtantly be nearly on a level with the ſurface, but without overflowing it while the hemp remains on the ground.

It is the cuſtom in ſome countries to form hemp-grounds, which are appropriated ſolely to this purpoſe: whereupon the author of a very judicious account of the culture of hemp, in the Memoirs of the Royal Society of Agriculture at Tours, juſtly obſerves, that, "beſides that all ſoils delight in a change of plants, hemp is ſo far from impoveriſhing the ground, that the leaves which fall from it become a ſufficient manure, and the depth to which the roots go, eſpecially if the crop of hemp be great, leave the ground ſufficiently looſe to ſow upon it even a crop of wheat immediately after the hemp has been pulled, without

any

any other expence than ſowing the ſeed and harrowing it in; or if turnips or a ſpring crop be more convenient to the farmer, theſe alſo will thrive well after the hemp. It is ſaid, that the hemp which grows on an eſtabliſhed hemp-ground is ſofter and more ſilky than that which is raiſed elſewhere: but the difference, if any, is very inconſiderable; for the hemp which grows in the other parts of Anjou, for example, is found to be as good as that which is produced by any of the few eſtabliſhed hemp-grounds in that province."

As it is eſſential to have the ground in exceeding fine tilth, the firſt ploughing ſhould be given it as early in the autumn as the huſbandman's other buſineſs will permit. Some are ſo curious in the preparation of their ground for hemp, that they give this firſt ſtirring by hand: and tho' it be a more tedious and more expenſive way than ploughing, they think that the difference of the crop repays them well. In whatever manner it be done, the ground ſhould be looſened as deep as poſſible, and laid rough, that it may be the better mellowed by the winter's froſt, eſpecially if the ſoil be ſtrong. If the hemp is to be ſown on ground purpoſely broken up, and which is covered with coarſe graſs, or other ſimilar productions, its ſurface ſhould be pared off and burnt; or it ſhould otherwiſe be brought to a perfectly fine tilth. The ground ſhould be ploughed again in February, or more early if the ſeaſon will permit; and then alſo ſhould be laid on the manure, whether of horſe-dung, or the ſcouring of ponds and ditches, after it has had time to ripen; for theſe are preferable to cow-dung; though all manures, which render the earth light, are fit for hemp. Mr. Du Hamel remarks, that marle is not, to his knowledge, uſed for this purpoſe. He likewiſe thinks, that it is beſt to dung the hemp ground every year before the winter ploughing, in order that the dung may have time to rot during that ſeaſon, and that the ſpring ploughing may afterwards mix it the more thoroughly with the earth: for all hemp grounds ſhould be well dunged at leaſt once a year.

To prepare the hemp ground thoroughly for receiving the ſeed, it ſhould have two or three good ploughings in the ſpring, or even more if the farmer's conveniency will permit, and the nature of the ſoil be ſuch as to admit of them; for the more frequently it is ſtirred in the ſpring, in proportion to the quality of the ſoil, the better the crop will be. About a fortnight or three weeks ſhould intervene between each of theſe ploughings, and they ſhould at laſt lay the ground quite ſmooth and even. If any lumps or clods of earth yet remain after all theſe ploughings, they ſhould be broken by hand; for the whole hemp ground muſt be as level, and of as fine a mould, as the beds of a garden.

The firſt ſpring ploughing ſhould be given acroſs the former; and before the next ploughing is the proper time to ſpread ſheeps dung, pidgeons dung, poultry dung, or whatever other ſuch like manures are uſed; though ſtill it is to be feared, that, if the ſpring prove dry, theſe hot dungs may burn the ſeed, which they would not do if they were laid on before the winter: but in this caſe a greater quantity of dung muſt be uſed, or leſs advantage muſt be expected from it.

The ſeaſon for ſowing hemp depends in a great meaſure on the quality of the ſoil. In dry light ground, it ſhould be ſown as ſoon as the danger of froſt, or other inclemency of the weather, is over, in the latter end of April or beginning of May, that ſo it may get up early, and, by covering the ground, prevent the danger of drought. In wet cold grounds, it ſhould be ſown later, that is to ſay, not till the ſun has exhaled the too great moiſture of thoſe grounds; and this may not be till the middle, or even the latter end of May. The author of the before-mentioned account of hemp, in the Memoirs of the Royal Society of Agriculture at Tours, adviſes to ſow hemp even ſo late as the latter end of June, in caſe the ſeaſon for it be not favourable ſooner; and he obſerves, that the crop ſown then will be as plentiful, and of as good a quality, as if the ſowing had not been delayed ſo long, eſpecially if a very dry ſeaſon does not come on immediately after. The truth of this is evinced by the experience of thoſe who are obliged to ſow a ſecond, and ſometimes a third crop, when their former ſowing has miſcarried through the inclemency of the weather, and particularly of froſt, which is a great enemy to hemp. Another reaſon too, which he aſſigns in favour of late ſowing of hemp, is, that the huſbandman may by this means have an opportunity of deſtroying the firſt growth of weeds, which would choak the hemp, if it were ſown before they had come up.

The huſbandman ſhould be particularly attentive to the weather, when he ſows hemp, for the ſeaſon then ſhould neither be too dry, nor too rainy. If either of theſe is the caſe, he had better defer his ſowing: though he ſhould, if poſſible, always chooſe a time juſt after a gentle fall of rain.

The hemp ſeed that is ſown ſhould always be of the growth of the preceding year, becauſe, as it is a very oily grain, its oil is apt to become rancid, if it be kept long, and the ſeed then loſes greatly of its vegetative power, inſomuch, that, when it is two years old, many of the grains will not riſe at all; and if it be older, a yet leſs quantity will grow. Experience has alſo proved, that, as in other grain, ſo likewiſe in this, it is adviſable every ſecond or third year to chooſe the ſeed from a ſoil different from that on which it is to be ſown.

When the ſoil is deep, and in fine order, it is beſt to ſow this ſeed thick, eſpecially if the hemp be intended for fine uſes, becauſe the plants run moſt into height, when they ſtand cloſeſt together, and their fibres are then by much the finer. They ſhould not, however, ſtand ſo very thick as to choak one another; becauſe this would occaſian a conſiderable loſs of plants. It is therefore neceſſary to obſerve a medium, the knowledge of which is eaſily acquired by practice: and indeed, in general, hemp grounds ſeldom are too thinly ſtocked with plants, unleſs when part of the ſeed has been deſtroyed by froſts, drought, or other accidents. The uſual quantity is three buſhels to an acre.

As ſown as the hemp ſeed is ſown, it muſt be carefully covered with earth, either by means of a harrow, if the ground has been ploughed, or with a rake, if it has been dug by hand; and beſides this precaution, the whole hemp ground muſt be conſtantly watered till the ſeed has riſen; for otherwiſe numbers of birds, and eſpecially pigeons, will deſtroy it entirely, without ſparing even the ſeeds that have been well buried. It is true, that pigeons and birds which do not ſcratch, do no great hurt to the grains of corn that are well covered with earth; but the huſks of theſe grains do not riſe up out of the ground with their green ſhoots, as thoſe of hemp always do; and then it is that theſe birds, miſtaking them for perfect ſeeds, tear them away with the young plants to which they adhere,

and

and thereby commit vaſt havock. So greedy are the pigeons, in particular, after theſe ſeeds, that none of the common ways of frightening birds will keep them off: nay, M. Du Hamel aſſures us, that he has ſeen ſtrong men, and even dogs, ſo wearied out with fatigue, as to be forced to give up the taſk, when the hemp ground has been large. Happily this troubleſome work does not laſt long; for when the hemp has put forth a few leaves, it requires no farther tending.

Though hemp cannot be weeded without great hazard of damaging the crop, becauſe whatever plants of it are twiſted, bent down, or broken, through inadvertence of the weeders, or by any other cauſe, never riſe again; yet if the weeds are ſo numerous and rank, as to endanger their ſmothering of the hemp, it is neceſſary to root them out, and the moſt careful perſons muſt be employed for this work, which, when rightly executed, is alſo attended with this farther advantage, that the pulling up of the weeds looſens the ſurface of the earth, and thereby forwards the growth of the plant.

In very dry ſeaſons, it will be proper to overflow the hemp ground, if it can be done. To this end ſome authors adviſe letting in the water from the ditches, as is practiſed for rice grounds. If any parts of the hemp ground are in danger of being burnt up, it will be adviſable to water them, or perhaps rather the whole in ſuch caſe, even by hand.

If, by any accident, the hemp grows very thin ſo as to be thereby in danger of branching out too much, and of becoming woody; this ſhould be an additional motive for keeping it perfectly clear of weeds, in order to let it remain for ſeed, which will be ſo much the better for the plants having ſtood thin.

The male hemp (which is the ſpecies that produces the *farina fœcundans*) ripens earlier than the female, generally by three weeks, or even a month: but the time of the ripening of either depends much on the nature of the ſoil. The male hemp ſhews its ripeneſs by turning yellow at top, and whitiſh at the bottom of the ſtem: but this ſort, in particular, ſhould be pulled rather before it is quite ripe, that is to ſay, while it is yet ſomewhat green; for if it be too ripe, its fibres will adhere ſo ſtrongly to the reed, as not to be ſeparated therefrom, without ſome loſs; neither will they be ſoft, and conſequently not ſo fit for domeſtic uſes, as thoſe of hemp that is pulled before it has attained to a perfect maturity.

The ripeneſs of the female or ſeed-bearing hemp, is known, not only by the ſame ſigns as that of the male, but alſo by the ſeeds beginning to turn brown, and by the capſules which contain them beginning to open.

As ſoon as the male hemp is ripe, it is pulled ſtem by ſtem, and with caution, not to injure the female hemp, which, as we before obſerved, muſt remain on the ground ſome weeks longer, that is to ſay, till it alſo is ripe, and then it muſt likewiſe be pulled ſtem by ſtem.

Each handful that is thus pulled ſhould conſiſt of plants, as nearly as poſſible of equal length, and their roots in particular ſhould be placed as even as can be. Some tie up each handful, eſpecially of the male hemp, with a ſtalk of hemp, then lay it in the ſun to dry its leaves and flowers, which they afterwards beat off, by ſtriking it againſt a tree or wall; they then put ſeveral of theſe handfuls together, ſo as to form a pretty large bundle, and in this condition they carry it to the watering place.

We have juſt mentioned what M. Du Hamel ſays of the common practice of drying the hemp before it is ſteeped: but we muſt here obſerve, that it is a matter of doubt, whether this plant ſhould be dried before it is ſteeped. Thoſe who are for drying it firſt, ſay, that the hemp becomes thereby ſtronger than when it is ſteeped without having been previouſly dried: for my part, I muſt confeſs, that this drying ſeems to me to be a needleſs trouble; for as it is neceſſary in the ſteeping of hemp, that a certain degree of putrefaction ſhould ariſe, ſufficient to deſtroy the texture of that glutinous ſubſtance which connects the fibres to the woody part of the hemp, it certainly is more adviſeable to lay the hemp in the water as ſoon as can be after it has been pulled, becauſe the more there is of the natural moiſture left in this glutinous ſubſtance, the ſooner the putrefaction will begin. If, either by deſign or accident, the hemp has been dried, the putrefaction comes on more ſlowly and more unequally, and the fibres contract a hardneſs which the ſteeping afterwards will not eaſily correct.

The common height of hemp, when full grown, is from five to ſix feet: but M. Du Hamel remarks, that the ſtems of the hemp which is cultivated near Biſchwiller, in Alſace, are ſometimes upwards of three inches in diameter at their bottom, and above twelve feet high. Theſe, indeed, are ſo deeply rooted, that even a very ſtrong man can hardly pull them up.

When the female hemp is let ſtand till its ſeed is perfectly ripe, its bark becomes woody, and ſo coarſe, that no future operation can bring it to a proper degree of fineneſs. For this reaſon, it is generally pulled before the ſeed is quite ripe: but as it is manifeſtly the huſbandman's intereſt to ſow none but the beſt ſeed, he ought not to grudge the ſacrificing of the goodneſs of a ſmall part of his hemp, to the ſuperior advantage of obtaining perfect ſeed, by letting a proper number of theſe plants ſtand till their ſeeds have attained full maturity. The judicious M. de Chateauvieux, whoſe attention extended to the moſt proper method of cultivating every uſeful plant, did not neglect ſo important an object as the quality of the hemp employed in cordage, and the means of obtaining its ſeed in the greateſt perfection. However, not having had opportunities of continuing his experiments long enough to draw certain concluſions from them, he invites all thoſe who have the public good at heart, to make experiments which may lead to the utmoſt improvement of the culture of this plant: "but, ſays this friend of mankind, theſe motives of œconomy are vaſtly inferior to the ineſtimable advantage of ſaving ſhips, their cargoes, and their crews, which often depends on the ſtrength of their ſails and cables."

On the twenty-ſixth of April, 1753, he ſowed ſix beds with his drill plough, placing ſix rows in each bed. The beds were ſeven feet wide, and the ſoil ſtrong, but in very fine tilth. He treated his plants with great care, according to the principles of the New Huſbandry: but both that and the enſuing year were unfavourable to the growth of hemp. However, he obſerves, in general, that his plants were five or ſix feet high, that their ſtems were large, and their bark very thick and ſtrong. They were very fruitful in ſeed, eſpecially the two outer rows, which had profited moſt by the hoeings. M. Aimen, from forty plants of hemp raiſed in the common way, and which might be deemed fine ones, had only a pound and an half of ſeed; but a ſingle plant which grew by itſelf, yielded him ſeven

pounds

pounds and a half, of much better ſeed than any that is produced in the common way. From hence it reſults, that it muſt be of great advantage to the huſbandman to ſet apart a ſpot of ground ſufficient to rear thereon as many plants of hemp, as will affore him ſeed enough for the purpoſe of ſowing, and to cultivate them according to the principles of the New Huſbandry.

In ſome countries, to complete the ripening of the ſeed, round holes are dug, about a foot deep, and three or four feet in diameter, in different parts of the hemp ground, and the handfuls of pulled hemp are ſet as cloſe together as can be in theſe holes, with their ſeed ends downward, and their roots uppermoſt; after which, to keep them in this poſition, the whole is tied round with bands of ſtraw, and the earth that was taken out of the hole is thrown up all round this great ſheaf, ſo as quite to bury the heads of the hemp, which, when thus covered, heat by means of the moiſture contained in them, in the ſame manner as a ſtack of green hay, or a heap of dung. This heat completes the ripening of the hempſeed, and diſpoſes it the more eaſily to quit its huſks; and when it has been brought to this condition, the hemp is taken out of theſe holes, where it would become mouldy, if it were left longer in them. But, as is juſtly obſerved in the excellent Memoirs of the Royal Society of Agriculture at Tours; it is hard to conceive, how an operation which tends to bring on at leaſt ſome degree of putrefaction, can ripen the ſeed; and therefore this muſt be at beſt a very dangerous practice, eſpecially as a ſeed ſo very oily as that of hemp, and conſequently ſo apt to become rancid, cannot but be liable to be rendered ſtill more ſo by this degree of heat.

In other places, where the crops of hemp are great, the huſbandmen do not bury the heads of their ſeed hemp in the manner above deſcribed, but only lay it in heaps, with the ſeed ends one againſt another: others, whoſe crops are ſmaller, content themſelves with ſpreading upon the ground a cloth to receive their hempſeed; and others again only ſpread their bundles upon a clean ſpot of ground, with all the heads turned the ſame way. The ſeed ends thus placed are beaten ſlightly, either with a ſtick, or a light flail. The ſeed which falls out eaſieſt is always the ripeſt and beſt, and ſhould therefore be reſerved for ſowing the next ſpring: and as to that which remains in the heads of the hemp after this operation, it is got out by combing the heads on the teeth of a ripple, which pulls off the leaves, the huſks of the ſeeds, and the ſeeds themſelves, all together. Theſe are gathered in a heap, and left in that condition for a few days, in order that they may heat a little, after which they are ſpread out to dry, then they are threſhed, and finally, the ſeeds are ſeparated by winnowing and ſifting. This ſecond ſeed is much inferior to the firſt, and accordingly it is uſed only for extracting oil from it, or feeding of poultry.

It is, on this occaſion, juſtly remarked in the Memoirs of the Royal Society of Agriculture at Tours, that by the threſhing of hemp there is always danger of bruiſing ſome of its ſeeds, and that the bruiſed ſeed will not grow, though it may be fit for yielding oil. Nor is this all; for by threſhing out the ſeed, there is a mixture of imperfect ſeed with that which is fit for ſowing; and this is the reaſon why huſbandmen have always found it neceſſary to ſow a greater quantity than would otherwiſe be requiſite, in order to make up for the uncertainty of its growth.

The method of ſeparating the fineſt grains of wheat for ſowing, by throwing the corn to a diſtance on a barn floor, is equally adviſable for obtaining the heavieſt and beſt hemp ſeed, where proper care has not been previouſly taken to provide ſuch. In this caſe, the ripple may be uſed to ſeparate the whole of the ſeed from the plant, and this will prevent the inconveniencies which ariſe from the threſhing or beating out of the ſeed.

The method of laying the hemp down in order to its being ſteeped, is to place it in bundles at the bottom of the water, there to cover it with a little ſtraw, to keep the dirt from ſticking to it, and then to load it with pieces of wood and large ſtones, to keep it down, ſo that it may be always five ar ſix inches below the ſurface of the water.

The intention of ſteeping the hemp in water is, to make its bark part the more eaſily from the reed, and to deſtroy the outer ſkin; or, if I may here be allowed the language of anatomiſts, the cellular membrane which connects the hemp with the reed. All this is effected by only a ſmall degree of putrefaction, ſo that it is dangerous to let the hemp lie too long in the water, for it will then be over ſteeped, that is to ſay, the water will not only have acted upon the outer ſkin and the connecting fibres, but it will alſo have leſſened the longitudinal coheſion of the fibres; in ſhort, the hemp will be too much rotted, and in this caſe the ſtrength of thoſe fibres will be proportionably impaired. On the contrary, when the hemp has not lain long enough in water, its bark adheres to the reed, its fibres are hard, and they cannot ever after be rendered ſufficiently fine. There is therefore a medium to be obſerved; and this medium depends, not only on the length of time that the hemp is to retain in the water, but alſo,

1. On the quality of the water; it being ſooner ſteeped ſufficiently in ſtanding water, than in a running ſtream; and ſooner in ſtagnant putrid water, than in that which is clear.

2. On the temperature of the air; for it requires leſs time to be ſufficiently ſteeped in hot weather, than in cold.

3. On the quality of the hemp; that which has been raiſed to a rich mould where it has not wanted for water, and which has been pulled whilſt yet a little green, being ſooner ſteeped to a proper degree, than that which has grown on a ſtiff or dry ground, and which has been let ſtand till it was quite ripe.

In general, when the hemp has been ſteeped but a ſhort time, its fibres are thought to be the better. Hence ariſes the opinion, that hemp ſhould not be ſteeped but in hot weather; and for this reaſon alſo it is that many, when the autumn is cold, defer the ſteeping of their female hemp till the next ſpring. It is likewiſe for the ſame cauſe that ſome prefer ſteeping their hemp in ſtanding water, or even in ſtagnant waters, that is putrid, rather than in ſpring or running water.

M. Du Hamel, to whom we are indebted for the foregoing remarks, ſteeped hemp in different ſorts of water, and it appeared to him, that the fibres of the hemp ſteeped in putrid ſtanding water were ſofter than thoſe of that which had been ſteeped in running water: but they contract in water which does not run, a diſagreeable colour, which does not indeed do any real injury to the hemp, for that which has been thus ſteeped is afterwards the moſt eaſily bleached; but yet, as this colour diſ-

pleaſes, and the hemp is the leſs ſaleable for it, endeavours are always uſed, if poſſible, to make a ſmall ſtream of water paſs through the ſteeping places, thereby to change the water in thoſe places, and to prevent its becoming putrid.

He ſucceeded likewiſe in rendering hemp fit to ſeparate from the reed, by ſpreading it upon a meadow in the ſame manner as is practiſed for bleaching of linen: but he found this method tedious and troubleſome; nor did the fibres of the hemp ſo prepared ſeem to him to differ much from thoſe of hemp ſteeped in the common way.

He alſo tried the boiling of hemp in water, in hopes of bringing it ſpeedily to the ſame condition as it is in when taken from the uſual place of ſteeping: but when, after having been boiled upward of ten hours, it was taken out of the water, in order to be dried, it was not at all fit for either peeling or breaking. It is true that, while it yet remained hot and wet, its bark ſeparated eaſily from the reed; but at the ſame time it peeled off like a ribbon; the glutinous ſubſtance which connects the longitudinal fibres, and makes them adhere cloſely to each other, not being at all deſtroyed, ſo that they could not be ſeparated, nor was it poſſible to divide them into fine threads. It is evident from what has now been ſaid, that no preciſe time can be fixed for the ſteeping of hemp; ſince the quality of the hemp, that of the water, and the temperature of the air, haſten or retard this operation.

M. Marcandier is of opinion that the fineſt and cleareſt water is always the beſt for ſteeping hemp; and he approves of the method of thoſe who make a kind of ditch on the edge of a river, where the water, being more ſtill and warm, ferments eaſily, and penetrates more quickly the parcels of hemp that are laid in it. When they are taken out of this ditch, it will be ſufficient to waſh them in the current of the river, which will carry off all the gum and mud that would otherwiſe cleave to them. He holds, that the hemp which has been ſteeped in rivers is always whiteſt, and of the beſt quality; and that that which has lain in ditches, pools, or reſervoirs of ſtanding water, is always of a bad colour, has a very diſagreeable ſmell, is loaded with dirt, and loſes a great deal in the dreſſing. Theſe are M. Marcandier's ſentiments on this ſubject, and if they are the reſult of his experience, as I preſume them to be, I cannot but regret his not having related the particulars of his experiments.

The judiciouſly accurate Memoirs of the Society which the illuſtrious ſtates of Brittany have eſtabliſhed for the improvement of Agriculture, Commerce, and Arts, are more particular in this reſpect, and conſequently more ſatisfactory. After obſerving, that it is ſtill undetermined whether hemp ought to be ſteeped in running or ſtanding water, that each cultivator of this plant gives the preference to the method he has been uſed to follow, and that naturaliſts have not yet written any thing deciſſive on the choice of the waters fitteſt for this preparation, the moſt important of any that hemp undergoes, becauſe it is on this that the eaſe and goodneſs of the hackling, ſpinning, and fabricating in a great meaſure depends; the Memoirs, I ſay, of theſe zealous patriots inform us, that one of the members of their office at Rennes thought that this diverſity of opinions and cuſtoms might proceed from running water's being, in fact, always preferable in ſome caſes, and from ſtanding water's being always the beſt in others. For example; in cold and rainy years the plant muſt be weaker, longer green, and fuller of juice, than in dry years, in which laſt the hemp will be ſtronger, but at the ſame time harder and more woody. Why then, ſay they, very judiciouſly, ſhould it be expected that the ſame waters applied to ſo different productions, ſhould have a ſimilar effect upon each?

To remove all doubt in this reſpect, the Society ordered ſome hemp to be pulled in different parts of the province of Brittany, and in different ſtates of growth. Some was pulled before it was ripe, ſome exactly when it was ripe, and ſome ſeveral days after it was ripe. Each of the parcels of theſe three ſorts of hemp was divided into two equal parts, one of which was laid to ſteep in running water, and the other in ſtanding water. They were afterwards hackled with very great care, and examined with the moſt ſcrupulous attention by a perſon thoroughly acquainted with the defects and good qualities of this commodity.

Minute accounts of every circumſtance attending theſe experiments, and of their reſult, were ſent to the office at Rennes; and the Society, ſenſible of the vaſt importance which the aſcertaining of this point may be of in many reſpects, deſired that they might be repeated in one and the ſame year on the hemp of all the diſtricts of the province, and the reſult of their firſt experiments was as follows:

1. There was a ſenſible difference between the ſame hemp pulled in the three-ſtates before mentioned. 2. All the hemp that was ſteeped in running water, was incomparably whiter than that of the ſame quality which was ſteeped in ſtanding water. 3. The hemp which was pulled before it was ripe, acquired the greateſt degree of whiteneſs. 4. The whole of the loſs of ſubſtance, upon ſumming up the waſte occaſioned by each particular preparation, was leaſt upon the whiteſt hemp; but that which had been ſteeped in ſtanding water, yielded a greater quantity of fine fibres, and the great loſſes in point of quantity fell upon the firſt dreſſing. 5. The hemp which was judged to be the beſt before it was hackled, did not always preſerve its ſuperiority when hackled. That which was at firſt looked upon as only of a middling, or even of an inferior quality, proved to be the fineſt and beſt after it was hackled. This obſervation is of great importance, eſpecially when the hemp is intended for naval uſes.

"We ſhall not, add theſe truly intelligent patriots, limit our inquiries to a bare repetition of theſe experiments. We purpoſe to extend them further, in order to have facts which may be entirely relied on. We ſhall cauſe the beſt and beſt prepared of each different kind of hemp to be ſpun by the ſame hand, into as ſmall and fine threads as the hemp is capable of affording, that ſo we may judge to which of the different manners of ſteeping this plant the preference is due, by the greater diviſion of which its fibres may be ſuſceptible. Theſe threads ſhall be exactly weighed, and ſhall undergo ſimilar preparations in exactly ſimilar leyes; after which they ſhall be weighed again, in order to judge of their goodneſs by the diminution which each ſhall have ſuffered in the leyes, and by the degree of whiteneſs which each of them ſhall acquire. Theſe experiments, though extremely uſeful in themſelves, are, however, only introductory to a greater enterprize: they will lay a ſure foundation for the improvement of every manufacture of hemp, and particularly of ſail-cloth, which is an article of the utmoſt importance to all commercial nations."

The

The memoirs of the Royal Society of Agriculture at Tours, for the year 1761, prefer river water, eſpecially that of rivers which run upon a bed of ſand, as the beſt for ſteeping of hemp; becauſe this water, being clear, renders the colour of the hemp brighter than it would otherwiſe be, as there is not any filth therein to ſully it: and it peels the more eaſily when ſo ſteeped, not being there liable to ſo great a degree of putrefaction, as to break the cohefion of the fibres of its bark. It is not, however, here meant, that the hemp ſhould be ſteeped in the bed of the river, becauſe the inequality of the motion of the water on the ſides, and in the middle of the hemp, would prevent the ariſing of that equal degree of putrefaction which is in this caſe eſſentially neceſſary. On the ſide of ſuch rivers, a hollow ſhould be dug three or four feet deep, and proportioned in extent to the quantity of hemp to be watered.

As it is contrary to law that the places for ſteeping hemp be made in running water, it would be of advantage to contrive them ſo that the waſte water from the ſteeping places ſhould run off upon paſture-grounds; becauſe the quantity of putrid vegetable matter which the water wherein hemp has been ſteeped carries along with it, would greatly enrich thoſe grounds; and with this view likewiſe all the water of pools or other places uſed for the ſteeping of hemp, ſhould be thrown out of them upon the graſs, as ſoon as the hemp has been removed.

It is eſſential to take heed, that the hemp be not, by any means, laid to ſteep in water in which there are any animals that might be apt to gnaw it; for theſe would cut aſunder, and totally deſtroys its fibres. Of this kind are, in particular, thoſe creatures which ſome people call freſh-water ſhrimps.

The common method of judging when the hemp has been ſufficiently ſteeped, is by trying whether the bark parts eaſily from the reed, and can be peeled off its whole length without breaking; for in this caſe it is thought to have been watered enough. However, it muſt alſo be allowed, that long practice enables the peaſants who cultivate hemp to give it, generally, a due degree of ſteeping, though they do ſometimes miſtake: and it is alſo to be obſerved, that it is the conſtant cuſtom of ſome countries to ſteep their hemp more than others. But the ſureſt way of all to diſtinguiſh whether the hemp has been ſteeped enough, is, as the Tours Memoirs remark, to take ſome of the ſtems out of the water, and then to try whether the extremity of the roots ſnaps off ſhort, and whether the bark ſeparates clear from the reed, its whole length; for in theſe caſes it is certain that the hemp has been ſufficiently watered, and it ſhould then be immediately taken out. If the bark does not ſeparate equally, but ſtops chiefly at the ſmall knots which appear on the ſtem, this ſhews that it has not been ſteeped enough.

The uſual duration of the ſteeping of the male hemp is from three to ſix days, according to the weather; and of the female hemp, from five to eight or ten days: but as only a ſmall degree of too much or too little ſteeping is equally hurtful, the utmoſt attention ſhould be exerted to hit the preciſe time of its being duly watered

Some injudiciouſly, neglect to waſh their hemp when it is taken out of the water, becauſe, ſay they, the filth brought out of the water with it will afterwards fall off: but, in the drying of the hemp, this filth gives it a bad colour, and the duſt which ariſes therefrom is extremely prejudicial to the health of the workmen.

When the hemp, after having been properly ſteeped, is taken out of the water, the bundles of it ſhould be untied, and ſpread upon the ſand, or upon ſtrongrocky ground; or, if neither of theſe be at hand, it may be laid upon a field that has been lately reaped, and where the ſtubble ſtill remains ſtanding. This ſtubble will keep it hollow, and it will dry the ſooner. Some dry their hemp by ſpreading it out and ſetting it upright againſt a ſunny wall, or by laying it along the ſide of a ditch. Graſs is not fit for laying it on, becauſe there will ariſe from thence a moiſture which will rot the hemp. For this reaſon it is, that the place where hemp is ſpread to dry, ſhould be as free as poſſible from every kind of damp. When the hemp is thorougly dry, it is bundled up again, and carried home, where it ſhould be kept in a very dry place till it is wanted for peeling or breaking.

The method of peeling hemp is ſo ſimple, that a deſcription of it would be needleſs; even children, and the aged and infirm may perform it with eaſe, by only taking one ſtalk after another, breaking the reed, and ſlipping off the bark. This may likewiſe become the employment of every perſon belonging to the farm in winter evenings, and at ſuch times as the weather will not admit of their working without doors. It muſt however be allowed, that there are ſome inconveniencies attending this method: the peeled hemp comes off in ribbands, which do not anſwer in the hackling ſo well as that which has been broken; more of the uſeleſs membranes, eſpecially towards the root, ſtill adhere to it, and, by increaſing its weight, render it, to uſe the common ſaying on this occaſion, better for the ſeller than for the buyer; beſides which, the hemp does not always peel off in equal lengths, and from thence ariſe conſiderable diſadvantages, and loſs in its future dreſſings.

The hemp which is to be broken ſhould firſt be rendered very dry; becauſe the reed will then be the more brittle, and therefore part the more eaſily from the bark. There are ſeveral ways of drying. Meſſieurs Du Hamel and Marcandier deſcribe a kind of cave or cavern, in which it is commonly dried in many parts of France. This cavern is generally ſix or ſeven feet high, five or ſix feet wide, and nine or ten feet long. A hollow under a rock is often properly made uſe of for this purpoſe: but as that cannot always be met with, it frequently is neceſſary to have recourſe to art. In this caſe, ſome form the top of their vault with dry ſtones, others cover it with broad flat ſtones, and others again only cloſe it with pieces of wood, over which they lay a quantity of earth ſufficient to ſtop up all the interſtices: but which ever of theſe methods is taken, the drying place ſhould be ſo ſituated as to be ſheltered from the north and north-eaſt winds, and be open to the ſouth, that it may receive the benefit of the ſun; becauſe the uſual ſeaſon for breaking of hemp is in clear froſty weather, when the buſineſs of the field is ſuſpended.

At about four feet above the floor of this drying place, and two feet from its mouth or entrance, three bars of wood, about an inch thick are placed acroſs the cavern, from ſide to ſide, and there fixed. On theſe bars is laid, about ſix inches thick, the hemp that is to be dried. A careful perſon, which generally is a woman, then keeps conſtantly burning, under the hemp ſo laid, a ſmall fire made of the fragments of the reeds of hemp that has already been broken or peeled. The perſon thus employed muſt be extremely watchful, becauſe, as this kind of fuel is ſoon conſumed, and muſt of courſe be frequently

quently replenished in order to keep a constant and regular fire all over the hearth (for this is absolutely necessary) very great care must be taken that the flame do not ever rise so high as to set fire to the hemp, which is exceedingly combustible, especially after it has been dried some time. The same person also takes care to turn the hemp from time to time, in order that it may be dried equally in all its parts; and likewise to put on fresh hemp, when the former is dry enough to be taken away and sent to the break.

Where but a small quantity of hemp is to be dried, an oven is doubtless the safest method; and when the hemp is dressed at home, it may perhaps be dried as fast by this means, as the other avocations of the family will admit of its being wanted. The only attention requisite in this case, is that the oven be not so hot as to endanger the fine and tender fibres of the hemp: for too great a heat may not only scorch them, but likewise so parch the oil in the hemp, as that the hemp will afterwards remain harsh and dry, and not be so easily whitened as it might otherwise be.

It also is usual, where the quantity of hemp is greater than can be managed with an oven, to dry it on a kiln; and this is a good method; provided the fire here be also very moderate, and made of such materials as do not blaze or sparkle, because of the great aptness of dry hemp easily to take fire. Coke is perhaps the very best fuel that can be used for this purpose.

The operation of breaking hemp, by which general term is however strictly meant only the breaking of the reed, which some call the bunn, or woody part of the stem, within the bark; for the bark itself, of which is made the filamentous substance that is spun and used in manufactures, only bends under the hand of the dresser, and does not break; this operation, I say, has hitherto generally been executed three ways, namely, by beating the hemp with beetles, which is a laborious and tedious work; or by the Dutch hand-break, which is in every respect much preferable to the beetle; or by fluted rollers worked by horses, wind, or water, but of choice by the latter, where a running stream can be procured. This last is more expeditious, and less laborious than either of the other ways; but is dangerous to the workmen employed therein, because, if by any inadvertence the rollers should catch hold of their fingers, the loss of a limb at least is inevitable. The only means of preventing this dreadful consequence, in such a case, is to a have an iron crow at hand, ready to clap instantly between the rollers, as is practised in sugar-works, which are of a similar construction.

The fluted rollers are undoubtedly the best instrument for breaking hemp, because the length of the stalk and strength of the reed of this plant must render the Dutch-break a very tedious operation, especially when large quantities of hemp are raised, as must be the case wherever a sufficiency of it is cultivated to answer the purposes of the great and important manufactures in which it is employed in this nation.

The Moravian hemp mill, used in America, is also a good instrument. It consists of a large heavy stone, shaped like a sugar loaf, with the small end cut off. A body of that form will go round in a circle, if it be moved on a plane. This is moved by a water mill, and the hemp, being laid on the floor, in its way, is bruised by the weight of the stone passing over it.

After the hemp has been broken, it undergoes a second operation, which is commonly termed swingling or scutching. The intention here is, to separate the reed from the hemp, and this is done by one or other of the following ways. In the first, the workman takes a handful of hemp in his left hand, and holding it over the edge of a board, strikes it with the sharpened edge of a long, flat, and strait piece of wood, commonly called a swingle hand, or scutcher. The author of the thirty-seventh letter in the Dublin Society's Weekly Observations recommends that the cutting edge of the scutcher be made of a circular form, in order that its greatest force may fall on the middle of the hemp, and thereby spread it, by which means it will be the more equally cleared of the remaining broken pieces of the reed. But this method is, at all events, very laborious and tedious; and therefore water mills have been erected, in which several scutches, fixed in the same axle-tree, are moved with great velocity. Here the work is performed with great expedition, and much less fatigue to the workmen; but a greater waste is made of the hemp, owing to the velocity with which this engine is turned.

Before the hemp thus prepared is heckled, it usually undergoes a third operation, called beetling, the design of which is to loosen and thereby more thoroughly separate its fibres. The beetles used for this purpose are moved either by hand or by water.

We have already described the instruments invented by Mr. Macpherson for performing these operations with very great facility, under the article flax, and therefore need not be repeated here. *See the article* FLAX.

Mr. Mercandier proposes, instead of scutching and beetling the hemp, to give it a second steeping after it has been peeled or broken, the better to soften the bark that may still remain hard, and not be easily brought to a proper degree of fineness. For this purpose, the hemp intended to be steeped a second time is divided into small parcels; these are tied loosely round the middle with a piece of packthread, in order that they may be managed easily without mixing or entangling them; and the hemp thus tied is laid in a vessel filled with water, where it is left, more or less time, according to the hardness of its fibres and the quantity of glutinous adherent matter still remaining on it. Three or four days are always sufficient for this purpose: but a less time will do, if the hemp wants only to be cleared of that adherent matter. When it has been thus steeped long enough, it should be washed very clean in a running stream; and if many of the fibres of the hemp are found to cling together in what our author calls ribbands, he advises to beat them in the manner that linen is beaten in bleaching.—It is safer to err in too little, than in too much steeping; because, after the fibres have been loosened in the break, they will be the more liable to be destroyed by even only a slight degree of putrefaction. When the fibres of the hemp are sufficiently disengaged from each other, they seem, while immersed in water, to be as completely dressed as if they had already passed through the hackle. After this watering, the parcels are opened, spread on a board, and laid in the sun to dry.

Mr. Marcandier observes farther, and likewise from his own experience, that, after this preparation, the hemp may be again steeped and washed in a leye of pot-ash or wood ashes, rendered perfectly clear of all filth. This will undoubtedly contribute to the removing of any such matter still remaining in the hemp, as must necessarily fall

off

off in the future preparations, before the manufacture made of the hemp is fit for uſe. And, indeed, a leye of this kind bids fair to be of ſervice in the preparing of flax as well as hemp; becauſe, both being thereby perfectly freed from every particle which muſt otherwiſe fall off in the future operations of heckling, ſpinning, bleaching, &c. the cloth or other manufacture made of them will be proportionably better and more durable The time taken up in bleaching will, in particular, be very much ſhortened thereby.

In the whole of this proceſs, the water ſhould be warm, becauſe warm water acts more powerfully than cold in diſſolving the impurities which are to be ſeparated from the hemp; and it is alſo an indulgence to the people employed in this buſineſs, who might otherwiſe be more apt to ſlur over their work. It will therefore be moſt adviſeable to perform this operation when the weather is moderately warm, thereby to ſave the trouble and expence of making fire to warm the water or the leye.

M. Marcandier having experienced the efficacy of horſe-cheſnuts in the bleaching of linen and cleanſing of woollen ſtuffs, made likewiſe uſe of a ſolution of them in water, as a leye for preparing hemp in the manner above deſcribed. The method of preparing this leye is as follows: the cheſnuts are peeled, and then raſped as fine as poſſible into ſoft water, in the proportion of two, or, at moſt, three nuts to every quart of water. This is done ten or twelve hours before the mixture is to be uſed, and in the mean while it is ſtirred from time to time, the better to diſſolve theſe raſpings and impregnate the water. The laſt ſtirring is given a quarter of an hour at fartheſt before the water is drawn off from the coarſer part of the raſpings, which ſinks to the bottom; and this is done, either by inclining the veſſel and pouring the leye off gently into another, or by lading it out by hand, while the water is yet white, and froths like ſoap-ſuds. In order to uſe this leye, it is made rather hotter than the hand can well bear, and the hemp is then ſteeped and waſhed in it, as in ſoap-ſuds.

The hemp thus prepared is carefully dried, laying the fibres ſmooth and as little intermixed as poſſible. When dry, it is doubled, and twiſted at the ends, or tied up in bundles. The farther buſineſs of the hemp-dreſſer need only be an eaſy beating of the hemp, and that chiefly to ſeparate the fibres that may have clung together in the drying, and to the common operations of the heckle. The danger ſo often fatal to the dreſſers of hemp, from the duſt drawn in with their breath, will alſo be hereby in a great meaſure avoided; and the hemp thus prepared will be white, ſmooth, ſoft, and flexible.

The ſame author extols highly the various uſes to which hemp thus prepared, and even its tow, or what is ſeparated from it by the heckle, may be applied. This hemp, he informs us, may be dyed like ſilk, wool, or cotton, and may be made into cloth, ſtuffs, and garments of all kind; and that a great advantage attending the uſe of this material is, that it will not be in danger of being deſtroyed by thoſe worms which eat woollen cloth. Theſe advantages attending hemp prepared in the manner which Mr. Marcandier has propoſed, may well deſerve the farther experiments and attention of our manufactures, eſpecially at Mancheſter, or wherever elſe our mixed ſtuffs are made.

HEPS, the fruit of the ſpecies of wild roſe, generally written hips.

HERBAGE, graſs, paſture in general. It is alſo uſed to ſignify the tythe and right of paſture.

HERD, a number of beaſts together, generally black cattle.

HERDSMAN, a keeper of herds, one employed in tending cattle.

HIDE, the ſkin of beaſts, but particularly applied to thoſe of large cattle, as bullocks, cows, horſes, &c.

HIDE *of Land*, was ſuch a quantity of land as might be ploughed with one plough within the compaſs of a year, or ſo much as would maintain a family; ſome call it ſixty, ſome eighty, and ſome an hundred acres.

The diſtribution of this kingdom by hides of land is very ancient, mention being made of it in the laws of king Ina. Henry I. had three ſhillings for every hide of land, in order to raiſe a dowry for his daughter: this tax was called hidage.

HIDE-BOUND, a diſtemper in horſes, when the ſkin ſticks ſo faſt to the back and ribs, that the hand cannot ſeparate the one from the other, without great difficulty; his body is at the ſame time lean, his back-bones ſtand up, his guts are for the moſt part deficient in moiſture, and his dung dry, and more offenſive than common.

If a horſe become hide-bound by hard riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or ſome other diſeaſe, if that be cured which is the cauſe, the effect will ceaſe; but if he has no fever upon him, and he is hide-bound only from lowneſs of blood and ſpirits, give him boiled barley, white-water, or the like, and when his fleſh is raiſed, harden it with good oats, beans, and moderate exerciſe.

HILL, an elevation of ground, leſs than a mountain, a down.

HILLOCK, a little hill.

HIVING *of Bees*, the placing a ſwarm of bees in a hive, in order to have the benefit of their labours. *See the article* BEE.

HOE, a tool made like a cooper's adz, to cut up weeds in gardens, fields, &c. This tool is commonly called the hand hoe.

This inſtrument is of great uſe, and ſhould be more employed in hacking and clearing the ſeveral corners, cracks, and patches of land, in ſpare times of the year, which would be of no ſmall advantage thereto.

Horſe HOE, a large kind of hoe, drawn by horſes, and uſed to ſtir the intervals in the New Huſbandry, and clear the corn from weeds.

Under the article CULTIVATOR, we have deſcribed the inſtruments uſed abroad for this purpoſe; and ſhall here give two very uſeful inſtruments of the ſame kind, invented by the ingenious Mr. Hewitt, who preſented them to the Society for the Encouragement of Arts, &c. where they may be ſeen. The following letter, deſcribing theſe inſtruments, was ſent by the inventor to the Society.

GENTLEMEN,

Peruſing the Eſſays on Huſbandry, I obſerved particularly, that the author page 105, expreſſeth hopes of ſeeing ſome "new invented plough, cheap, ſimple, and rightly calculated for deſtroying weeds; keeping plants clean; and ſtirring the ground;" and, page 106, further ſays, "now as moſt people prefer uſeful, and cheap, to elegant and expenſive inventions, it is natural to wiſh for a hoe plough intirely ſimple, and not coſtly. For the mechaniſm of thoſe deviſed hitherto, by the ingenious lovers of agriculture, is of ſo perplexed, and complicate a na-

a nature, that it will no ways anſwer the common purpoſes of huſbandry: but, being perpetually out of order, will throw the poor ploughman into deſpondency; and the rather, as neither he, nor the country plough-wright, can comprehend how to rectify any defects, or accidents, except with extreme difficulty."

The very name of a hoe-plough ſuggeſted the idea of an inſtrument, which I ſhall call a horſe-hoe; whoſe conſtruction is intirely new, ſimple, and much leſs coſtly than a common plough. Such as country plough-wrights, and ſmiths, are able to make; and ſuch as common ploughmen are able to uſe: and which ſeems, according to the hopes of the aforeſaid author, to be rightly calculated for deſtroying weeds; keeping plants clean; and ſtirring the ground.

This horſe-hoe, a model of which I beg leave, in the moſt reſpectful manner, to preſent to this honourable Society, I hope may be of a very extenſive uſe in agriculture, as it muſt be much more efficacious, and expeditious too, than any kind of hand-hoe for the deſtruction of weeds, and ſtirring the ground. For if the inſtrument does not cut below the crown, or head, of the roots, ſuch roots will ſprout again, and the firſt labour become fruitleſs; which indeed is too often the caſe of hand-hoeing: as the labourer, ſometimes, only ſcratches the ſurface of the earth, and ſhaves off the leaves of the weeds, the roots remaining intire and unhurt, to vegetate again. With this inſtrument, the huſbandman may hoe the ground ſo deep, that it will infallibly cut aſunder the roots of every weed it meets with, below the crown or head; and, conſequently, either deſtroy them, or at leaſt greatly check their future growth that ſeaſon.

This inſtrument is calculated for hoeing the intervals between the generality of plants in ſtraight rows: ſuch as tranſplanted lucerne, beans, peaſe, and turnips, ſown with a drill plough, &c. In large gardens, hop-grounds, nurſeries, and plantations of young trees, much labour, and expence, in hand-hoeing, may probably be ſaved by the uſe of it.

In the county of Norfolk (and probably in many other places) the huſbandmen, in the months of March and April, preparing their lands for barley, generally give them a certain number of earths, according to the phraſe of that country; or, in other words, plough them a certain number of times. In thoſe months the weather is frequently very dry; and the ſoil being turned over and over again, and expoſed to the ſun and wind, becomes ſo duſty, that a great part of the ſeed will not grow without rain; which ſometimes not falling in many weeks after the ſeed-time, cauſeth the crop to conſiſt of different growths; ſo that when the firſt grown crop is ripe for the ſcythe, the latter is but juſt eared. This evil, perhaps, may, in ſome meaſure, be remedied by the uſe of this horſe-hoe, inſtead of the common plough, at that ſeaſon. For this will ſtir, and looſen, the earth as effectually, as the other; and, at the ſame time, neither remove, nor turn it over, which ſeems to be beneficial, in a drought, upon very light and ſandy ſoils.

With reſpect to foul ſummer fallows too, it may be of ſingular ſervice. The common plough buries the weeds, of which many grow again. This horſe-hoe will cut their roots aſunder, below the ſurface of the earth; and by leaving their foliage above it, expoſed to the ſummer ſun, the greateſt part of them will wither and die: ſo that they will not give the huſbandman much more trouble the remaining part of the ſummer. And, as this hoe may be eighteen or twenty inches brood, two acres of land may be hoed by it, as ſoon as one acre can be ploughed, by the common plough.

This new inſtrument is intended for public benefit; and to the conſideration of the public, as well as of this honourable Society in particular, it is freely ſubmitted. If it be judged an uſeful implement in huſbandry, well; if not, the pleaſure that has ariſen from the hope of doing good, has amply rewarded, for his trouble, the inventor, who has the honour to ſubſcribe himſelf,

GENTLEMEN,

Hadleigh, April 19, 1766.

Your moſt humble, and obedient ſervant,

WILLIAM HEWITT.

P. S. Since I had completed this model, I apprehended, that its utility might be rendered ſtill farther extenſive, by a very ſmall alteration; therefore, gentlemen, I take the liberty of laying before you another model, calculated for hoeing the furrows between wheat ridges, which all farmers acknowledge to be very good huſbandry, though many of them are deterred from the practice of it, for want of a cheap expeditious method of putting it in execution. An inſtrument of this kind, I am perſuaded, will very greatly expedite that uſeful work: and if it meets with your approbation, gentlemen, many lovers of improvement in agriculture may be induced to give it a fair and impartial trial.

An Explanation of the HORSE-HOE, *Plate* XVII. *Fig.* 3.

A repreſents a ſmall round curved iron-bar, fixed upon each end of the axle of the wheel, by which the horſe-hoe is drawn.

B, the wheel three feet in diameter.

C c two flat iron-bars, three feet long, fixed upon the axle of the wheel, at D d, and to the ſides of the hoe; at E e, by bolts and ſkrews: upon theſe bolts, as well as the axle of the wheel, they are moveable.

F, a ſmall round iron-bar, faſtened at each end, into the two bars; C c (to ſtrengthen them) at G g, from and to G, theſe bars may be ſtraight. From G to E, let them be curved.

H, the hoe itſelf; the breadth of which may vary according to the different diſtances of the rows of plants, whoſe intervals are to be hoed.

K K, two little flat curved iron-bars, fixed by bolts, upon which they are moveable, to the bars C c. Each of them paſs through a ſtaple, fixed into the ſides of the hoe at L l. In both theſe little bars is a row of holes. In each of the ſtaples, is one hole; and, directly oppoſite to them, one hole in each of the ſides of the hoe: and, by means of two bolts, paſſing through theſe holes, and ſome of the holes in the bars K K, the hoe is fixed to any poſition; ſo that the ground may be hoed as near the ſurface, or as far below it, as is neceſſary.

M M, two wooden handles, fixed to the two ſides of the hoe, and to each other, by the croſs bar O; as long, and as high from the ground, as the handles of a common plough.

Figure 4. repreſents the horſe-hoe, intended for hoeing the furrows, between wheat ridges: which differs only, in one reſpect from the other. That hoe is flat; this is curved.

curved. The breadth, and curvature of this, muſt depend intirely upon the breadth, and curvature of the furrows, to be hoed. In which reſpect, every ſenſible farmer can eaſily direct the ſmith how to form it. But, after all, if any perſons be inclined to make trial of this inſtrument, I would adviſe them not to truſt to a verbal deſcription, but to ſend for a model of it to Thomas Tillet, a very ingenious ſmith at Hadleigh in Suffolk.

HOEING, the breaking or dividing the ſoil by tillage, while the corn or other plants are growing thereon.

It differs from common tillage, which is always performed before the corn or plants are ſown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This ſort of tillage is performed various ways, and by means of different inſtruments. Land which, before the tillage, would have yielded little, though the more it is tilled before ſowing, the more plenty of corn it yields, yet, if tilled only before the ſowing, will always have ſome weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reaſon for an after tillage, ſuch as that by hoeing. But there is another conſideration that yet more requires it; this is, that as ſoon as the ploughman has done his buſineſs, by ploughing and hoeing the land, after ſowing, the ſoil, of its own accord, begins to undo it all again by tending towards its original texture and ſpecific gravity again; the altering of which was the only buſineſs of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles, or new ſuperficies, is the great buſineſs of the plough and harrow; but, as ſoon as their uſe is over, the earth begins to coaleſce again into its own form, the particles unite together, and the artificial pores in a great meaſure cloſe up. The ſeed is nouriſhed in a worſe ground than it was firſt put into, and the more the plant grows up, and requires a larger ſupply of food, the worſe the paſture becomes. While nouriſhment is thus denied the growing plants, they are at the ſame time choaked with weeds, which being of a hardier nature than they, will grow with leſs ſupplies, and therefore thrive more vigorouſly, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in ſome degree, with the uſe of tillage and dung to crops of uſeful plants; but they have ſo ill managed the time of giving theſe aſſiſtances to nature, that there is no doubt but one third part of the nouriſhment raiſed by dung and tillage, if it were given to plants and corn at many proper ſeaſons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of ſowing.

Nature, by what ſhe does in the animal œconomy, ſeems to point out to us ſomething like the remedying this by hoeing; for when the teeth, as the plough, have tilled that ſoil or maſs which is earth altered; and when the ſaliva and the juices of the ſtomach have ſerved to divide and attenuate it, as the ſalts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhauſted by the numerous mouths of the lacteals, ſituate in the inteſtines. This laſt operation of theſe juices ſeems analogous to the meliorating the ſoil by hoeing, after the plants are grown, and are becoming fit for uſe.

Tranſplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by tranſplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be uſed to them with advantage, to their utmoſt ſtanding, and make them vigorous all the while.

The roots of a plant are all neceſſarily broken off in tranſplanting, and it requires ſome time for it to ſtrike a whole ſet of new ones; and if the earth about it is not kept thoroughly moiſtened all this time, the new formed roots will not be able to ſhoot, and the plant will ſtarve in the midſt of plenty: but, on the contrary, in hoeing, the ſame advantage of a new paſture for the plant is obtained, by the breaking the particles of the earth, and at the ſame time no more of the roots are broken off than can eaſily be ſupplied, and the reſt remaining in their places, the plant continues growing without that ſtop or decay, which muſt happen on tranſplanting, and which it recovers only by degrees. It is obſerved, that ſome plants are the worſe for tranſplanting: lucerne and ſaintfoin are never ſo good after tranſplanting, as when they are left in their native places, at the ſame diſtances; and finochia, removed, is never ſo good and tender as when it is not.

This laſt plant receives ſuch a check from tranſplanting in its infancy, that it has afterwards a diſeaſe like the rickets, which cauſes knots and ſwellings in it, that ſpoil it as a delicacy. All the tap-rooted plants ſuffer by tranſplanting; for it is neceſſary in this to cut off the long-main root, which afterwards, however good the ſoil may be, never arrives at the length it otherwiſe would have had, and which was neceſſary for the ſucceſs of the plant.

One great benefit of hoeing is, that it keeps plants moiſt in dry weather, the advantage of which to their growth is eaſily ſeen. This good office it performs on a double account. Firſt, as they are better nouriſhed by hoeing, they require leſs moiſture, and conſequently carry off leſs; for thoſe plants which receive the greateſt increaſe, having moſt terreſtrial nouriſhment, carry off the leaſt water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats, being ſown on a piece of ground well divided by tillage and dung, will come up and grow well without rains, when the ſame grains ſown on another part of the ſame land, not thus dunged or tilled, will ſcarce come up at all without rains, or if they do, will wait wholly for the rains for their growth and increaſe.

The hoe alſo, particularly the horſe-hoe, for the other does not go deep enough, procures moiſture for the roots from the dews which fall moſt in dry weather; and theſe dews ſeem to be the moſt enriching of all moiſture, as it contains in it a fine black earth, which will ſubſide from it in ſtanding, and which ſeems fine enough to be the proper pabulum, or food for plants.

A demonſtration that the tilled earth receives an advantage from theſe dews, which the untilled does not, is this; dig a hole in any piece of land, of ſuch a depth as the plough uſually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and bottom of the hole, will be found moiſt, while all the reſt of the ground, at the ſame depth, is dry. Or, if a field be tilled in lands, and one

land be made fine by frequent deep ploughings, while another is left rough by inſufficient tillage, and the whole field be then ploughed acroſs in dry weather, which has continued long, every fine land will be turned up moiſt, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly ſoaked with rain, will continue wet longer than fine tilled land adjoining to it, yet, this water ſerves rather to chill than to nouriſh the plants ſtanding in it, and to keep out the other benefits of the atmoſphere; it leaves the ground much harder alſo than before, when it is finally exhaled out of it; and when, at length, the earth is then hardened, it can receive no benefit from any thing leſs than a deluge of rain, which ſeldom falls till the ſeaſon of vegetation is over.

As fine hoed ground is not ſo long ſoaked with rain, ſo the dews never ſuffer it to become perfectly dry. This appears from the flouriſhing ſtate of plants in hoed ground, while others near them, but in ground not hoed, are ſtarved for want of nouriſhment. The common opinion is againſt this, but obſervation proves it to be true againſt the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather for fear of letting in the drought, as they call it; whereas hoeing this is the only method of keeping away the drought, and without either this, or watering, they muſt periſh in theſe ſeaſons. *Tull's Horſe-Hoeing Huſbandry.*

HOG, the name of an animal too well known to need any deſcription here.

Theſe creatures are very advantageous to the countryman, not only for their great increaſe, but alſo becauſe they feed upon what would otherwiſe be of no uſe or advantage, but would be thrown away; as whey, waſhings of tubs, grounds of drinks, diſh-water, grains, &c. and their fleſh being beſt ſalted, or kept in pickle, may be eat in the ſpring, when other meat is at the deareſt; beſides the help it affords to the taking off the produce of the garden, and the variety of diſhes of the offal. Swine are indeed very greedy, and very apt to root up ground, and break the fences; and therefore the greater care muſt be taken to keep them both well rung and well yoked.

The largeſt ſwine, and the greateſt number for any particular places, are bred in Leiceſterſhire, and ſome parts of Northamptonſhire, and in the clayey countries adjacent; probably from the large quantities of beans and peaſe ſown in thoſe parts.

The wild kind are not ſo large as thoſe juſt mentioned, but are much more hardy, and better meat.

In the choiſe of hogs, chuſe ſuch to breed out of as have long, large bodies, are deep ſided and bellied, that have a ſhort noſe, thick thighs, ſhort legs, high claws, thick neck, a ſhort ſtrong groin, and a thick chine, well ſet with ſtrong briſtles.

To have too many ſows in one yard is not good, for their increaſe is ſo great, that they will, for want of food, not only devour whatever comes in their way, but eat one another: for a ſow will bring forth pigs three time in a year, that is, at the end of every ſixteen weeks. It is common for them to have thirteen or fourteen pigs at a litter; but the ſow can rear no more than ſhe has teats to ſuckle them with; the reſt muſt therefore be deſtroyed, or put to other ſows. If the ſow miſs the time of going to boar, that ſhe might in courſe have done, give her ſome oats parched in a pan, in her waſh, or the ſmall end of a runnet bag, and it will cauſe her quickly to go to boar. The pigs which you rear, after you have choſen out the beſt for boars and ſows, the male muſt be gelt, and the ſows ſpayed; the ſpayed gelts, as the farmers call them, are eſteemed the moſt profitable, becauſe they have a much larger quantity of fat upon their inwards, than other hogs. Young ſhoots, which are ſwine of about three quarters of a year old, are beſt for pork, and thoſe of a year, or a year and a half, for bacon. The beſt age for a ſow to bring forth pigs, is from one to ſeven years old; and the beſt age for the boar, is from two to five years old, at which time it is beſt to geld him, or ſell him for brawn; the beſt pigs to rear, are thoſe which are pigged in the ſpring, and thoſe pigged in March for pork in October.

The beſt way of taking care of ſwine, is to feed them ſo as to keep them in middling plight, till you deſign to fat them; for if you keep them too fat, it will endanger their health; and too lean will render them too ravenous. It is good to give them ſuch ſwill as you have every morning and evening, to make them come home to their ſtyes. The reſt of the day, let them graze, and get ſuch food as they can; but when the corn is upon the ground, you muſt be careful to keep them within bounds. Moiſt ſedgy grounds are good for them, the roots of which they will eat; and all ſorts of haws, heps, ſloes, crabs, acorns, maſt, cheſnuts, &c. with which, if you have plenty enough to fat them, their fleſh will eat much better and ſweeter than if fatted in a ſtye. Some, indeed ſay, their fat will not be ſo ſolid, nor ſo profitable, and therefore they commonly ſhut them up for a week or ten days, and feed them with dry peas; but this is a miſtake, experience having ſhown, that hogs fatted with acorns only have their fat as ſolid as thoſe fatted with peas. In fatting hogs in ſtyes, they obſerve to give them meat often, and but little at a time, that it may be always freſh; and likewiſe to give them as much water as they will drink, and to keep them very clean, which will help their fatting, and improve the taſte of their fleſh. But where the huſbandman lives remote from woods, or the year ſhould fail of producing acorns or maſts, they commonly fat them wholly in ſtyes with peas, if cheap; if dear, the meal of barley, rye, or offal corn, according as they are cheapeſt, which they mix with water, whey, or ſkimmed milk: with theſe they feed them till fat, which will commonly be in about a month's time, and then they feed them with peas a little before they kill them.

Obſerve, that every ſtye have a yard well paved with ſtone, if poſſible, for the hog to go out and eaſe and air himſelf, that he may keep his lodging the cleaner.

In Leiceſterſhire they have a very eaſy method of fattening great numbers of ſwine, which they do by ſtacking up their peas and beans in the form of a ſmall cottage. This they ſet near ſome running brook, and hedge a yard in round about it; taking ſome part of the ſtream into the yard for the hogs to drink at; into this yard they turn ſuch a number of hogs as they think their peas or beans will fat, where they let them live till their proviſion is conſumed, cutting the rick down, and giving it to them as they can eat it. *Mortimer's Huſbandry, vol* I. *p.* 244.

HOG-SHEEP, or *Hoggrel*, a ſheep of a year old.

HOLT, a wood.

HOLM, an iſland in a river; it alſo ſignifies the holly.

HOOP, a meaſure equal to a peck, or quarter of a buſhel.

HOP, a well known plant of the reptile kind, whoſe flower is a principal ingredient in beer, and other malt-liquors.

A rich, deep, mellow, dry ſoil, rather inclining to ſand than clay, is, in general, beſt adapted to the cultivation of hops; but a black garden mould is excellent for this purpoſe. Stiff clays, ſpewy lands, ſuch as are apt to be overflown by floods, hard gravels, ſtony grounds, very ſandy ones, and ſuch as are not at leaſt a foot and an half deep, are altogether improper for hops.

The beſt ſituation for hop-grounds is ſuch as inclines to the ſouth, or lies open to it, ſo that they may have the benefit of the ſun during the greateſt part of the day. It muſt alſo be open, for the air to have a free paſſage and circulation between the plants, and it ſhould be ſo ſheltered to the eaſt, north, and weſt, that neither the froſty winds in the ſpring may cut off the young ſprouts, nor the more ſtormy ones in ſummer and autumn deſtroy the full grown hops.

The ground and ſituation being choſen, the next buſineſs is to prepare it for the planting. In many parts of England, when the ground is broken up for this purpoſe, the plough goes firſt, and men follow it with the ſpades, with which they dig one ſpit deep in the furrows where the plough has paſſed, throw up the earth thus dug, and ſo continue to plough and dig till the whole is done. Either this tillage, if it be well performed, or the deep ploughings, croſs-ploughings, and harrowings, by which careful huſbandmen prepare their land for corn, will fit this for being ſown with turnip ſeeds in the end of July, or beginning of Auguſt, and if the turnips are hoed twice, ſo as to be left about eight inches aſunder, they will yield a good crop, the weeds will be deſtroyed, and the ground will be rendered looſe and fine. Another good ploughing after the turnips are taken off, will, with the enſuing winter mellowing, render it fit for being planted with hops in the ſpring.

The beſt time to begin ploughing is in October, in order that the ſoil may be properly prepared to receive the benefits of the winter's froſts, rains, and ſnows; after which, in the beginning of ſpring, it ſhould be well and deeply ploughed again, and well harrowed; and after another ploughing in March, which will be of very great ſervice, it ſhould be harrowed fine, and laid as even as can be.

When the ground is in proper readineſs for planting, ſtretch along a ſtraight ſide of the field, at fifteen or twenty feet diſtance from the hedge, and parallel to it, a line with knots or rags tied in it, as far aſunder as you deſign your hills to be, and ſtick in the ground a ſharp-pointed ſtick at every knot, as marks for the places where the hills are to be made; continue the line in this manner the whole length of the ground, and from this firſt row you may mark out the reſt of the field, either in ſquares, chequer-wiſe, at the intended diſtance of the hills, or in the quincunx form, where the hills of every row lie oppoſite to the middle of the firſt, in a triangular form.

The diſtance of the hills ſhould be, in ſome meaſure, regulated by the nature and goodneſs of the ſoil: but, in every caſe, they ſhould be far enough aſunder to admit the hoe-plough at all times without danger to the plants. If the ſoil be dry and ſhallow, ſix or ſeven feet will be a convenient diſtance: but if it be rich, moiſt, and apt to bear large hops and leaves, it may be right to allow eight or nine feet between the hills.

The moſt proper ſeaſon for planting hops, is from the beginning of March to near the middle of April, at the time when they begin to ſhoot. The Kentiſh huſbandmen approve likewiſe of October: but the common ſorts are not to be procured then, unleſs it be from a ground that is to be dug up and deſtroyed; beſides which, there is ſome danger of their rotting in the earth, if the winter ſhould prove very wet.

There are ſeveral ſorts, though the botaniſts allow but one ſpecies of hops. The moſt eſteemed are, the long white, the oval, and the long ſquare garlic hop. Theſe differ from each other in the colour and ſhape of their bells, or hops, in the degree of bearing, and in their time of ripening. The long white is moſt valued, becauſe it is a great bearer, and produces the moſt beautiful hops; for the beauty of hops conſiſts in their being of a pale bright green colour. The oval hop is beautiful, but does not yield ſo large a crop. There is a ſort of this kind of white hop, called the early, or rath hop, which ripens a week or ten days before the common, and is therefore of advantage to thoſe who would be firſt at market: but it is tenderer than the other, and does not bear near ſo plentifully. The long ſquare garlic hop is the greateſt bearer, more hardy, and ſomewhat later ripe than the former; but by reaſon of its redneſs towards the ſtalk, it is not ſo beautiful to the eye, and therefore is not ſo much eſteemed as the other ſorts.

Few hop grounds are without ſome plants of a ſort of hop which many call the female hop, but very erroneouſly; for the female hop is that which is cultivated for uſe, and this, which others name more properly the wild hop, is the male. Towards the middle of July, it puts out a great number of long looſe bunches of ſmall flowers, not at all like the true hop; and in ſomewhat leſs than a month after, that is to ſay, juſt before the true hop begins to bloſſom, they ripen, and with the leaſt motion of the wind, ſhed a farina, which is wafted all around, and is by ſome, not improbably, thought to be of uſe to impregnate other hops. Thoſe who are of this opinion adviſe, therefore, to leave one or two hills of them ſtanding in the hop-ground. But the common practice is to mark them at their firſt appearance, and to root them out afterwards, becauſe they do not bear bells or hops, and as they are generally the ſtrongeſt plants, ſets might otherwiſe be taken from them by miſtake.

There is alſo a poor ſtarved hop, called a wild hop, which is not judged to be a diſtinct ſort, but a hop which has degenerated for want of culture.

The planter of hops ought to be extremely careful in the choice of his plants, or ſets, particularly in regard to the kind of the hop: for it is a great trouble and loſs to him, when his garden proves to be a mixture of ſeveral ſorts of hops, ripening at different times. He who plants the three ſorts abovementioned, viz. the early, the long white, and the ſquare hop, in three diſtinct parts of his ground, will have the conveniency of picking them ſucceſſively as they become ripe.

Hop ſets are cuttings from the roots or branches which grow from the main root or ſtock. They ſhould be procured, if poſſible, from grounds planted with none but the ſort which is deſired; and they ſhould be from five to ſeven or eight inches long, with three or more joints or buds on them, all the old bind and hollow part of the ſet being cut off.

The ground being prepared for planting, as before directed, towards the latter end of February, or in the beginning of March, if the ſoil be light, or late in March, if it be ſtrong and moiſt, make, in the places marked out by the ſticks ſtuck in them, holes about twelve or ſixteen inches wide, and of a depth proportioned to the nature of the ground. In general, ten or twelve inches will be a ſufficient depth. If the ground be ſhallow, and you meet with hard clay or gravel, by no means enter into this, for you would then make a baſon to retain water; but, in ſuch caſe, inſtead of going deeper, raiſe up a ſmall hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half, or two feet deep, and you will find the hops thrive the better; for their tap roots naturally run downward.

When all things are ready for planting, fill up the holes with the mould before thrown out of them, if it be naturally good, after having firſt broke it fine with a ſpade: but if the ſame earth be not rich enough, make uſe of fine freſh mould, or of the compoſt provided for this purpoſe. About a peck or two of this will be ſufficient for each hill; but no new dung ſhould be put into the hole on any account.

Then, with a dibble, or ſetting ſtick, ſuch as gardeners generally uſe for planting of beans, make five or ſix holes, the depth of your ſets, one in the middle, perpendicular, and the reſt round about, ſloping and meeting at the top near the center: put your ſets therein, ſo that they may ſtand even with the ſurface of the ground; and then preſs the mould cloſe to them, and cover them with fine mould two or three inches thick. A ſtick ſhould be placed on each ſide of the hill to ſecure it.

The ground being thus planted, all that is to be done in the following ſummer, is to keep the hills and alleys clear from weeds by frequent hoeings; to dig the ground in the month of May, and to carry off all the ſtones that are turned up by digging; to raiſe a ſmall hill about the plants; to throw ſome fine mould on their roots; and, in the latter end of May, or beginning of June, to twiſt all the vines and branches together into a bunch or looſe knot, and lay them thus twiſted on the top of the hill.

Towards the latter end of February, or in the beginning of March, in the ſecond year, when the weather is kindly, open the hills, and with a ſharp knife, cut off the ſhoots of the firſt year to within an inch of the old ſtock, together with all the younger ſuckers that have ſprung from the ſets, and cover the ſtock with fine earth. To keep the knife ſharp, you ſhould have a whetſtone always by you at dreſſing.

In the third and following years, when you dig your hop-ground in February, let the earth be taken away with a ſpade or hoe, round about the hill, very near them, that you may the more conveniently come at the ſtock to cut it: then in fair weather, towards the beginning of March, if your hops be weak, begin to dreſs them; but if they are ſtrong, and in heart, the middle or latter end of March will be the beſt time; for late dreſſing reſtrains their too early ſpringing, which is the cauſe of many injuries to the hop.

After the hops are dreſſed in the ſecond year, the next buſineſs is to pole them. Poles of only ten or twelve feet long will do then; but in the third year, by which time they come to their full bearing ſtate, they will require poles of full ſize: this, if the ground be rich, and the hop vigorous, will be from ſixteen to twenty feet, or even more; or there will be danger of loſing great part of the crop.

If the hop be weak, and the ground not rich, the poles ſhould not be more than from fourteen to eighteen feet long for fear of impoveriſhing the root; for the hop will ſoon run itſelf out of heart if over poled; ſo that, as was ſaid before, there is more danger in over poling than in under poling; neither can a good crop be expected from an over poled ground, becauſe the branches which bear the hops grow very little till the buds have over-reached the poles, which they cannot do when the pole is too long. Two ſmall poles are ſufficient for a hill in a young ground.

Towards the latter end of July hops begin to bloſſom, about the beginning of Auguſt they bell, and in forward years, they are ſometimes ripe at the end of Auguſt, or beginning of September. When they begin to change colour, or are eaſily pulled to pieces, when they emit a fragrant ſwell, and when their ſeeds begin to look brown and to grow hard, you may conclude that they are ripe: then pick them with all expedition; for a ſtorm of wind will do them great miſchief at this time; and hops picked green and bright, without bruiſing or diſcolouring, will ſell for a third part more than thoſe that are otherwiſe.

When the poles are drawn up in order to be picked, the vines around them ſhould be cut aſunder, at the height of about three or four feet from the ground; for the cutting of them lower, eſpecially while the hops are green, would occaſion ſo great a flowing of the ſap, as would weaken and hurt the root.

The moſt convenient way of picking them is into a long ſquare frame of wood, called a bin. This frame is made of two poles, or pieces of wood, each nine or ten feet long, and three or four inches broad, joined together at about a foot and a half from each end, by two other pieces three feet long; and it is ſupported by four legs three feet and a half high; ſo that there remain in the middle of it a ſpace ſix feet long, three wide, and three and a half deep. In this ſpace is fixed a coarſe linen cloth, or hop-bag, cut open on one ſide, and hung hollow, either by hitching it on tenter-hooks along the inſide of the frame, or by ſtretching it on the outſide with wooden ſkewers, to receive the hops as they are picked. Three men or women, or four boys or girls, may ſtand on each ſide of the frame, and pick two poles at a time.

When you have raiſed ſome poles, bring them with the hops and vines on them, and lay them lengthwiſe upon the frames; or erect a forked prop at each end of the frame, and reſt the poles thereon, in order to their being picked. There is no occaſion to ſtrip the vines from the poles in order to their being picked. The workmen who raiſes the poles generally carries them to the frames, and the latter being very light, may be eaſily removed from one part of the ground to another.

The ripeſt hops ſhould be firſt picked: but if the hops appear to be equally ripe in all parts of the plantation, it is beſt to begin to pick them on the eaſt or north-ſide of the ground, the more effectually to guard againſt the ſouth-weſt wind's breaking into the garden.

Having choſen a ſpot of ground which contains eleven hills, place the bin upon the hill which is in the center, and after theſe are picked, remove it into another ſpot of the ſame extent, and ſo proceed till the whole is finiſhed.

The hops ſhould be picked as free as poſſible from leaves and ſtalks; for theſe would be of greater preju-

dice

dice to the ſale, than any ſeeming advantage which might be expected from their weight. The bin ſhould be emptied two or three times a day into a large cloth of coarſe linen, in which the hops ſhould be immediately ſtitched up with ſkewers, and carried directly to the oaſt, or kiln, to be dried: for if they remain long in the bin, or cloth, they will ſweat and be diſcoloured.

If any brown hops are met with in the picking, care ſhould be taken to ſeparate them from the reſt, by putting them into a baſket by themſelves.

If the weather be very hot, or rainy, cut no more hops than may be picked in an hour: but, if it be poſſible, gather them in fair weather only, and when they are dry; for this precaution will ſave ſome expence of coals, and contribute to the better preſervation of the colour when they are dried. No hops ſhould be gathered when the dew is on them, for that would make them become mouldy.

When you have taken the poles from the hills, twiſt together the remaining ends of the binds, that they may not get among people's legs, and hinder their work.

Before you draw the poles, obſerve whether the hops of one pole be entangled above with thoſe of another, and if they are, cut them aſunder with a ſharp hook fixed at the end of a long pole.

If the garden be large, it may be worth while to raiſe a ſhed in the midſt of it, to ſhelter the pickers and the hops from the ſun and rain; and to lay hops in overnight, to be picked early the next morning before the dew is off the other hops. This ſhed will alſo ſerve for preſerving your poles in winter.

If there be either rain or dew upon the hops at the time when they muſt be gathered, ſhake the pole, and they will dry the ſooner. If they are over-ripe when gathered, they will ſhed their ſeeds in which the chief ſtrength of the hop conſiſts; nor will they then look ſo green, but ſomewhat brown, which is a great diminution of their value. It therefore is better to pull the hops, a little before they are ripe, than to wait till they are full ripe. Four pounds of undried hops, thorough ripe, will make one pound of dry; and five pounds of hops ſcarcely ripe, though in their full prime, will make no more when they are dried.

There are two principal ſorts of hops, viz. the green and the brown. The former yields by much the beſt colour when dried, and the other is the moſt plentiful bearer.

Brown hops are fit for brown ale, but the hops for fine pale beer muſt be green; for which reaſon theſe laſt are moſt eſteemed.

As faſt as you pick hops, dry them on a kiln; otherwiſe they will change colour: but if you cannot dry them immediately, and muſt keep them a little while, ſpread them on a floor, and by that means the damage which they will receive in a day or two will not be great.

They who have five or ſix acres of hops, may employ ten frames at a time in picking.

If any of the rath-ripe, or early hops, which bloſſom and ripen a week or ten days ſooner than the other ſorts, happen to be intermixed in the ſame plantation, they ſhould be watched carefully, in order to their being gathered in time; for if they hang till they are over ripe, they will ſhed their ſeeds, turn brown, and thereby not only become bad themſelves, but ſpoil the ſale of the others with which they are mixed. It is therefore adviſable to mark at the bloſſoming ſeaſon, the hills in which they are, in order to dig them up and replant thoſe ſpots, for the trouble of pulling them up ſeparately, when they are ſcattered here and there in a hop-ground, and of carrying them, ſometimes a conſiderable way, to a convenient place, to be picked, is very great, and cannot be avoided otherwiſe than by either baniſhing them totally, which would not be quite conſiſtent with the huſbandman's profit, as they fetch a good price by their coming firſt to market; or, which is the beſt way, by planting them in a garden by themſelves.

Very particular care ſhould be taken that the hops be thoroughly and equally dried. In this lies the greateſt dificulty in the art and management of them: for if they are over-dried, they will change colour, look brown, and be judged to be burnt, whereby their value will be greatly diminiſhed; and if they be under-dried, they will loſe their colour and flavour. Experience has ſhewn, that an handful only of under-dried hops will ſpoil many pounds of others, by taking away their fine ſmell and colour.

The beſt way of drying them is with a charcoal fire, on a kiln covered with hair-cloth, of the ſame form and faſhion as is uſed for drying of malt, under which head this common ſort of kiln will be more particularly ſpoken of hereafter. It is found to ſuffice in places where only a few hops are raiſed, and a great deal of malt is made: but where the hop-planters have a much greater quantity of hops than can be dried in due time on their malt-kiln, (for hops, as was ſaid before, ought to be dried as ſoon as poſſible after they are picked) they build, in the following manner, ſeveral ſmall kilns on purpoſe for drying of hops.

Eight or ten acres of hop-ground require a building of about ſixty feet long, and fifteen wide in the clear. At one end of this building is a boarded room, to receive the green hops which are brought from the hop-ground, and which lie ſpread out there till there be room to put them on the kilns: at the end of the building is another large boarded room, for receiving the hops from the kiln when they are dried, and for them to lie in heaps to ſweat till they are fit for bagging. In the intermediate part of the building, three or four kilns, of eight or ten feet ſquare each, are conſtructed thus, cloſe to one another.

If the middle building is, we will ſuppoſe, twenty-eight feet long, and fifteen feet wide, there will be room for three kilns of eight feet ſquare each in the clear, and for their reſpective walls. Theſe kilns ſhould lie in a line along the back wall, and will come forward above nine feet; ſo that there will remain a paſſage five feet wide and twenty-eight feet long at the front of their kilns.

To form each kiln, build the walls of brick, nine inches thick, and let each of the four ſides be eight feet long in the clear, and ſeven feet high. The principal parts of the kiln are, in the upper part, the bed or floor whereon the hops are to be laid in order to their being dried; and in the under part, the furnace, ſteddle, or lanthorn, for the fire. The bed or floor in a kiln of eight feet ſquare, ſhould be about ſix feet from the lower floor, ſo that it will be about a foot below the top of the wall. This foot of wall riſing above the bed, ſerves to keep in the hops on the kiln, and for men to walk upon round about the kiln, to look to the drying of the hops. The bed, or floor, may be made of wooden rails an inch ſquare, laid very even and level, into a croſs beam, a quarter of an inch aſunder: or if the kiln be arched below, the floor may be laid with long bricks, or ſtones reſting on the tops

of the arches, at about two inches diſtance from each other.

In making the lower part of the kiln, place the mouth of the furnace at the bottom, in the middle of the front wall of the kiln, and let it be fourteen inches wide and ſixteen high. Joining to the mouth of the furnace on the inſide, build the ſteddle or lanthorn, of brick, four inches thick. This lanthorn ſhould be fourteen or ſixteen inches wide, three feet perpendicularly high in the ſide walls, and it ſhould reach from the front wall of the kiln to within a foot and an half of the back wall; ſo that there will be room for a man to paſs between it and the back wall, and the length of the lanthorn thus made will be about ſix feet. On its ſide walls, bricks of a foot length are to be raiſed on their ends, leaning to and bearing upon one another, ſo as to form a covering like the roof of a houſe; or the top of the lanthorn may be regularly arched over.

In building the ſide walls of the lanthorn, after you have laid the two firſt rows of brick, leave at the end of every brick in the three or four following rows, an open ſpace or hole, four or five inches wide, checquer-wiſe, both in the ſides and in the back, and lay the uppermoſt row or two of bricks cloſe together, as in the bottom rows, for the better ſupport of the roof. By this means there will be three or four rows of holes, which are deſigned to convey the heat equally to all parts under the hair-cloth. The roof ſhould be well plaiſtered on the inſide with hair and lime, that it may the better reflect the heat.

In the front-part of the kiln, on one ſide of the furnace, and at the height of two feet from the ground, a ſmall door ſhould be made, three feet high, and two wide, ſo that a man may eaſily get in to ſet every thing to rights about the ſteddle. There ſhould alſo be ſteps or ſtairs to go to the upper floor, where the hops are dried; and as there is a paſſage below, five feet wide, along the front of the kilns; ſo will there be, directly over head on the upper floor, a like paſſage, which will be of uſe for bringing green hops from their room, and laying them on the kiln, and for carrying them to the ſtore-room after they are dried. For greater conveniency, both theſe rooms ſhould be on the ſame floor as the upper-part of the kiln.

A farther caution neceſſary to be obſerved, is that no holes be made within a foot of the fire-place or mouth of the furnace, and that all the parts about the kiln be conſtructed ſo cloſe that no wind or air may poſſibly get in. The farther end of the ſteddle ſhould be built of brick up to the top, with holes in it as in the ſides.

The kiln ſhould be ſquare, and may be ten, twelve, or fourteen feet over at the top; but there ſhould be a due proportion between the height and breadth of the kiln, and the ſize of the ſteddle where the fire is kept, viz. if the kiln be twelve feet ſquare on the top, it ſhould be nine feet high from the fire, and the ſteddle ſhould be ſix feet and an half ſquare; and ſo proportionably in other dimenſions. Theſe kilns are made at a ſmall expence.

In drying of hops, firſt lay the hair-cloth very even on the bed or floor of the kiln, and ſpread the green hops thereon, about ſix inches thick, laying them with a rake as ſmooth as poſſible, not thicker in one place than another. Let the kiln be moderately warmed before you lay on the hops; then keep an even and ſteady fire under them, but not too fierce at firſt, for fear of ſcorching them; and let not the fire ſlacken, but rather increaſe it till the hops are nearly dried, leſt the moiſture or ſweat, which the fire has raiſed, fall back and diſcolour the hops. For theſe reaſons chiefly it is, that no cool air ſhould be ſuffered to come into the kiln while the hops are drying, and that wind, which would make the fire burn too violently, ſhould not be permitted to blow on the mouth of the furnace. After the hops have lain thus about ſeven, eight, or nine hours, have left off ſweating, and leap up when beaten with a ſtick, then turn them upſide down with a broad malt-ſhovel, or ſcoop made for that purpoſe, or caſt them up into a heap in the middle, and afterwards ſpread them equally on all ſides. Let them remain in this ſituation for two or three hours more, till every hop, if poſſible, be thoroughly and equally dried; and then with a hair-cloth, remove them to the heap where they are to lie till they are bagged. If they do not dry in one place ſo much as in the reſt, which may be perceived by touching them with a ſtick or wand, and obſerving whether they rattle when ſo touched, as they will do when dry; make them thinner in the places where they rattle leaſt. They muſt not be turned while they ſweat; for that will burn them, and make them loſe their colour. The fire may be diminiſhed a little before they are turned, and refreſhed again afterwards: but thoſe times excepted, the heat ſhould be kept as equal as poſſible.

Hops are fully dried when their inner ſtalks become brittle and break ſhort on rubbing, and when their leaves fall off eaſily, and feel very criſp. When they crackle and leap a little, as they will do upon the burſting of their ſeed, then is the time to take them off the kiln.

If the fuel uſed for this purpoſe be either wood or turf, it ſhould be charred firſt, becauſe ſmoke ſpoils the colour and ſmell of hops. Charcoal made of old rotten poles is moſt commonly uſed. Cinders of ſea-coal are alſo very good; and it is found by experience that Kilkenny coal dries hops perfectly well, becauſe it does not ſmoke, and gives a conſtant uniform heat for a long time. The fire ſhould be made at the mouth only of the furnace; for the air will diſperſe the heat ſufficiently from thence to all parts of the kiln: and that it may be conſtantly of the ſame gentle degree, neither too ſtrong nor too weak, it may be of ſervice to make uſe of a thermometer, by marking upon which the degree of heat proper for drying hops, as ſoon as that degree is aſcertained by experiment, you may always after know how to regulate your fire with great exactneſs: for, putting the thermometer within-ſide the kiln for a ſhort time, you may obſerve, by the height of the liquor, when the heat is come to a right pitch, and when it is either too high or too low, and ſo increaſe or ſlacken the fire accordingly. Any ſervant may, with the help of this inſtrument, be able to mend and correct the fire with great certainty, and not be liable to commit miſtakes, which often prove exceedingly detrimental to the hops. When you begin drying, loſe no time in the proſecution of that work, but employ people night and day, to attend it with the utmoſt care, till it be finiſhed. A large malt-ſhovel full of charcoal, thrown into the mouth of the furnace of a kiln eight feet ſquare, will laſt an hour.

It is obſerved that hops dried in the ſun loſe their richneſs of flavour, as other herbs do when they are dried that way. If they are laid on a floor to dry, without uſing a fire, they will loſe their ſtrength, be apt to ſweat or ferment upon change of weather, and not be fit for packing. Fire exhales their watery parts, and, by retaining the oily, preſerves their flavour and colour.

Hops break all to powder if they are bagged hot from the

the kiln. To prevent this, they ſhould be laid in a heap, to ſweat and grow tough; and if they are then covered for a while cloſe with blankets, to keep the air from them, they will bag the better. There is no limited time for their ſweating, that varying according to the weather: three or four days are commonly ſufficient; but it is a certain rule, that when the hops feel moiſt and clammy, and can be ſqueezed in the hand, or trodden cloſe, without breaking, they are then fit for bagging. The harder they are trodden, the better they will keep.

The bags proper for this occaſion are made of coarſe linen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about two hundred and a half weight of hops. The ſmall bags, called pockets, contain about half that weight.

The manner of bagging is thus: make a round or a ſquare hole, but a round one is moſt convenient, about twenty-ſix or thirty inches over, in the floor of the chamber where the hops are laid in heaps after they are ſweated. This hole ſhould be large enough to receive the bag, and for a man to go up and down it with eaſe. Tie with a piece of packthread, an handful of hops in each lower corner of the bag, to ſerve as handles for the more eaſy lifting or removing of the bag; and, with packthread, faſten the mouth of the bag to a frame, or hoop, ſomewhat larger than the mouth of the hole, that the hoop may reſt on its edges, and ſtrong enough to bear the weight of the hops when the bag is full, and of the man who treads them. The upper part of the bag being thus fixed by the hoop, let the reſt of it hang down through the hole; but not ſo near to the lower floor as to touch the ground: then throw into it a buſhel or two of hops, and let a man go into the bag, and with ſhoes that have no heels, tread the hops down on every ſide, as hard as he can, till they lie cloſe. Let more hops be then caſt into the bag, and be trodden down as before; and continue this till the bag is full. When that is done, untie it from the hoop, let it down, and ſew up its mouth as cloſe as you can, obſerving at the ſame time to tie up ſome hops in the upper corners, as was done before in the lower. The harder the hops are preſſed, and the cloſer and thicker the bag is, the longer and better the hops will keep.

When they are thus bagged, lay them upon a boarded floor, and in a dry place; for dampneſs would injure them greatly. At the ſame time all proper meaſures muſt be taken to guard againſt rats and mice, which, though they do not eat hops, are very apt to ſpoil them, by making neſts and lodging in them.

Some, in treading the hops, uſe a fifty pound weight, faſtened to a rope, and placed in the middle of the bag. The man in the bag treads about with his feet, and lifts it up now and then, to preſs them the cloſer together.

As ſoon as the hops are picked, ſtrip their haulm or vines from off the poles, and, as your laſt work, lay the poles up ſo that they may be preſerved. This is done either by ſtacking, piling, or houſing.

The ſtacking is performed thus: ſet up three poles, like an erect triangle, or rather ſix poles, let into the ground with an iron crow, and placed circularly, but inclining to one another ſo as to meet, and be tied faſt together with bands of the haulm of the hops, within a yard of the top. The poles deſtined for the ſame ſtack ſhould then be erected ſpeedily againſt this frame; for if they are ſuffered to lie on the ground, eſpecially in wet weather, they will receive more damage in a fortnight, than by their ſtanding out upright all the reſt of the year. When they are ſet up, about three hundred to a ſtack, bind them round with a rope of twiſted haulm, to keep them together. By this means the outer poles only are ſubject to the injuries of the weather, and keep all the inner ones dry, excepting at their tops and bottoms, the former of which are for the moſt part expoſed to the air, as the latter are to the moiſture of the earth. It is therefore a good method to cover the top of the ſtacks of poles with haulm, and to lay ſtones, bricks, or ſand, at their bottom, to preſerve their but ends from rotting.

Many chuſe to pile them up lengthwiſe, in different parts of the hop ground, laying three or four old poles athwart at bottom, to preſerve them from the dampneſs of the earth, and ſetting ſeveral poles erect in the ground on each ſide of the pile to prevent its ſlipping: they then lay the poles on one another, placing the ſmaller ends inwards, and the bigger outward; ſo that the pile ſhould conſequently be ſomewhat longer than the poles: and when it is raiſed high enough, they bind it acroſs with ropes of twiſted haulm, to keep it upright and ſteady, and then cover it with haulm, to defend the poles from rain. This is a better method than the former; but the beſt way of all to preſerve the poles, is to build in the hop ground a ſhed or two, which may ſerve as a ſhelter for picking the hops in ſummer, and laying up the poles in winter, with leaſt danger of their being hurt or ſtolen.

From October to March, there is nothing to be done in the hop ground, but to provide and bring manure into it, and to give the alleys their winter's digging or ploughing.

If you bring dung into your ground, be ſure it be well rotted, and lay it on the alleys to mix with the earth, but not on the hills, dung being apt to produce vermin, which are extremely injurious to hops. Cold dungs, ſuch as cows and hogs dung, are better for hops than horſe dung, unleſs the ſoil be cold and wet, and then hot dung, ſuch as that of ſheep, and even of pigeons, will not be improper.

A ſmall dunging every ſecond year is ſufficient, and a plentiful dunging will ſerve for three years, if the ſoil be tolerably good.

Dung was formerly more in uſe for hop grounds than it is at preſent, experience having ſhewn, that lime, limeſtone, gravel, ſea-ſand, marle, eſpecially the ſhelly marle, aſhes, and many other manures, are the moſt proper means of correcting the defects of ſoils, anſwer the end better, and laſt much longer.

The management of the hop ground during the third and every ſubſequent year (for it will continue to yield good crops during upwards of twenty years, if it be rightly cultivated) is the time as above directed; ſo that it will require pretty conſtant care and attendance, eſpecially from the beginning of March to the end of September. This you may lay down as a certain rule, that the more pains you take, and the greater expence you are at, in the due culture of the ground, and management of the hops, the greater will be your profit.

The charge of an acre of hop ground, in moſt parts of England where hops are cultivated, is computed thus: three pounds for the huſbandry, four pounds for the wear of the poles, five pounds for picking and drying, one

pound

pound ten ſhillings for dung, one pound for rent, and ten ſhillings for tythe; in all, fifteen pounds a year: but in ſome places they pay four or five pounds an acre yearly for the rent of the land.

The hop planters in England commonly agree with hop dreſſers, to do, for three pounds to three pounds ten ſhillings an acre, all the huſbandry part, in which is included the ſummer and winter digging of the ground, the pruning and dreſſing of the hops and hills, the poling and tying, ſeveral hoeings and making up the hills from time to time, the laying of the dung on the ground, and all other works, except the bringing of the dung to the ground, and the picking and drying of the hops, which laſt buſineſſes are performed by others; ſo that a gentleman has little trouble with his hop ground: he need only be careful that the undertaker does every part of the work in its proper ſeaſon; and it is ſo much the intereſt of the undertaker to be punctual in this, that, if he neglects hoing when the weeds appear, he will, by ſuch neglect, greatly multiply his trouble and labour in rooting them out afterwards.

An Engliſh acre requires about three thouſand poles, the price of which varies according to their ſize. In ſeveral places it is uſual to give as many ſhillings for an hundred poles as the poles are feet long; ſo that for an hundred poles of twenty feet long they give twenty ſhillings; but where poles are in great plenty, they give but fifteen ſhillings for thoſe of that length. A recruit of five hundred poles yearly will keep an acre of hop ground in conſtant repair; ſo that poles are about a third part of the yearly charge, the picking and drying are eſtimated at another third, and the reſt is laid out in the managing of the ground.

The hop planters in England reckon, that they have but a moderate return when the produce of an acre of hops does not ſell for more than thirty pounds. They frequently have fifty, ſixty, eighty, or an hundred pounds for an acre; nay, ſome have got conſiderably more than even this laſt ſum for every acre of hops, at a time when the crops of other hop grounds have failed in general, and theirs have ſucceeded. But if, on one hand, ſuch extraordinary profit, being very uncertain, is not to be depended upon; ſo, on the other, it ſhould not be paſſed over quite unnoticed, becauſe it is among the chances which may make amends for failing years. Upon the whole, if the total charge of an acre of hops is computed as above, at fifteen pounds a year, and its produce, at an average of years, at thirty pounds only, the clear profit from an acre will be fifteen pounds a year.

Though it be common in England to ſee ten, twenty, thirty, or more acres of hop ground in the hands of one man; and though ſome who ſpare neither care, induſtry, or expence, to make their plantations of this kind flouriſh, receive two thouſand pounds a year for their hops, notwithſtanding the high price of labour, manure, and every other article relating to their proper management; yet the intelligent huſbandman will eaſily perceive, that it is not prudent for poor farmers, or men of ſmall fortune, to engage far in this branch of improvement; for it requires a pretty conſiderable ſtock at firſt to cultivate a large plantation, to furniſh it with poles, and to perform every other requiſite. The expence will neceſſarily be great, and the undertaker muſt expect to lie out of his money for two or three years, before he can have any return of profit; and even when his hops do come to their bearing-ſtate, and he is in hopes of making good the charges he has been at, a bad ſeaſon may fruſtrate his expectation. Small parcels of hops, ſuitable to the abilities of the farmer; for even the pooreſt may eaſily ſpare time and labour, to plant a few of them in a corner of his garden, or other ground, and to ſet ſallies, willows, or aſh, for poles in his hedges or elſewhere, will yield him a pretty profit, without his laying out any money: ſo that, in ſetting forth the expences and riſk which attend the cultivation of hops, we mean only to caution the huſbandman, whoſe circumſtances are but middling, againſt embarking too far in this branch of agriculture.

Ground that is fit for the raiſing of hops, is alſo fit for the raiſing of hop-poles of one kind or other. But to be more particular: low, wet, cold, marſhy, boggy ſoils, or ſuch as are ſituated near rivers, are fit for all the aquatic ſorts, ſuch as poplars, abeles, alders, willows, oſiers, and ſallies, which produce hop-poles in four or five years from their firſt planting. If the ſoil be dry and warm, or a ſtrong, mellow, rich loam, the aſh and the cheſnut, which make the beſt poles for hops, will thrive greatly therein, and be fit for poles in nine or ten years from the time of ſetting them: and if theſe are planted around the hop-ground, they will both ſhelter the ground, and afford a ſupply of poles, without the expence of carriage. Elms alſo are quick growers; and when they are planted cloſe together, they ſhoot up tall and ſtrait, and make good poles.

Aſh and cheſnut poles, but eſpecially thoſe of cheſnut, are ſo tough and durable, that three ſets of them will laſt twenty years: but poles of alder, poplar, abele, oſiers, or ſallies ſoon rot, or become brittle; ſo that five ſets of them, at leaſt, will be requiſite within that time. The aquatic kinds are therefore to be eſteemed only for a firſt ſupply, till the plantations of aſh and cheſnut become fit for the future recruit of the hop ground.

Hops are, like other vegetables, liable to various accidents and diſtempers, the principal and moſt fatal of which are the fly, the ſen or mould, the mildew, and what the planters call fire-blaſts.

The reverend Dr. Hales, treating of this ſubject in his excellent Treatiſe of Vegetable Statics, gives us the following account of the ſtate of hops in Kent, in the year 1725, which he received from Mr. Auſten of Canterbury, who was a very great planter, and an accurate obſerver.

"In mid April, not half the ſhoots appeared above ground; ſo that the planters knew not how to pole them to the beſt advantage.

"Upon opening the hills, this defect of the ſhoot was found to be owing to the multitude and variety of vermin that lay preying upon the roots, and of which the increaſe was imputed to a long and almoſt uninterrupted ſeries of dry weather for three months before. Towards the end of April, many of the hop vines were infeſted with flies.

"About the 20th of May there was a very unequal appearance, ſome vines being run ſeven feet, others not above three or four, ſome juſt tied to poles, and ſome not viſible; and this diſproportionate inequality in their ſize continued through the whole time of their growth.

"The flies now appeared upon the leaves of the forwardeſt vines, but not in ſuch numbers here as they did in moſt other places. About the middle of June the flies increaſed,

increaſed, yet not ſo as to endanger the crop; but in diſtant plantations they were exceedingly multiplied, ſo as to ſwarm towards the end of the month.

"On the 27th of June ſome ſpecks of ſen appeared. From this day to the 9th of July the weather was very dry. At this time, when it was ſaid that the hops in moſt parts of the kingdom looked black and ſickly, and ſeemed paſt recovery, ours held out pretty well, in the opinion of the moſt ſkilful planters. The great leaves were indeed diſcoloured, and a little withered, and the ſen was ſomewhat increaſed.

"From the 9th of July to the 23d, the ſen increaſed a great deal; but the flies and lice decreaſed, it raining much daily. In a week more, the ſen, which ſeemed to be almoſt at a ſtand, was conſiderably increaſed, eſpecially in thoſe lands where it firſt appeared.

"About the middle of Auguſt the vines had done growing both in ſtem and branch, and the forwardeſt began to be in hop, the reſt in bloom: the ſen continued ſpreading where it was not before perceived, and not only the leaves, but many of the burs alſo were tainted with it.

About the 20th of Auguſt ſome of the hops were infected with the ſen, and the whole branches were corrupted by it. Half the plantations had eſcaped pretty well hitherto, and from this time the ſen increaſed but little: but ſeveral days of wind and rain in the following week diſtorted the plants ſo that many of them began to dwindle, and at laſt came to nothing; and of thoſe which then remained in bloom ſome never turned to hops, whilſt many of thoſe which did were ſo ſmall, that they ſcarcely exceeded the ſize of a good large bur.

"We did not begin to pick till the 8th of September, which is eighteen days later than we began before. The crop was little above two hundred on an acre of ground, and not good. The beſt hops ſold this year at Way-hill, for ſixteen pounds the hundred."

As a farther means of inveſtigating of the cauſe of this pernicious diſtemper, Dr. Hales relates the following experiment, which he himſelf made on hops. In the month of July, he cut off two thriving hop vines, near to the ground, in a thick ſhady part of the garden, and left the pole ſtill ſtanding. He ſtripped the leaves from off one of theſe vines, and left them on the other, and then ſet their ſtems in known quantities of water in little bottles. That with leaves imbibed in a twelve hours day, four ounces, and that without leaves only three fourths of one ounce.

He took another hop-pole with its vines on it; and having carried it out of the hop-ground into a free and open expoſure, theſe plants imbibed and perſpired there double the quantity of the before-mentioned which had leaves on it, in the hop-ground. This ſeems to indicate that the reaſon why the hop vines on the outſide of gardens, where they are moſt expoſed to the air, are ſhort and poor, in compariſon of thoſe in the middle of the ground, is, becauſe, being much drier there, their fibres harden ſooner, and therefore they cannot grow ſo kindly as thoſe in the middle of the ground, which, by the ſhade and ſhelter they afford each other, are always kept moiſter and more ductile.

From this perſpiration of their fluid, the ſame attentive obſerver of nature forms the following calculation. There being a thouſand hills in an acre of hop-ground, and each hill having three poles, and each pole three vines, the number of vines will be 9000, each of which perſpiring four ounces, the ſum of all the ounces perſpired by an acre in twelve hours of day will be 36000, equal 1575000 grains, equal 62007 cubic inches, or 220 gallons, which being divided by 6272640, the number of ſquare inches in an acre, it will be found, that the quantity of liquor perſpired by all the hop-vines will be equal to an area of liquor as broad as an acre, and $\frac{1}{101}$ part of an inch deep, beſides what is evaporated from the earth.

Now this quantity of moiſture, in a kindly ſtate of the air, if daily carried off, is ſufficient to keep the hops in a healthy ſtate: but in a rainy moiſt ſtate of air, without a due mixture of dry weather, too much moiſture hovers about the hops, ſo as to hinder, in ſome meaſure, the kindly perſpiration of the leaves, whereby the ſtagnating ſap corrupts, and breeds mouldy ſen, which often ſpoils whole tracts of, till then, flouriſhing hop-grounds.

This was the caſe in the year 1723, when, for twelve or fourteen days, almoſt continual rains fell, about the latter half of July, after four months of dry weather; upon which the moſt flouriſhing and promiſing hops were all infected with mould, or ſen, in their leaves and fruit, while the then poor and unpromiſing hops eſcaped, and produced plenty, becauſe they, being ſmall, did not perſpire ſo great a quantity as others, nor did they confine the perſpired vapour ſo much as the large thriving vines did in their ſhady thickets.

The planters of hops remark, that when a mould, or ſen, has once got poſſeſſion of any part of the ground, it ſoon over-runs the whole, and that even the graſs, and other herbs under the hops, are infected with it. The reaſon probably is, that the exceeding ſmall ſeeds of this quick growing mould, or moſs (for ſuch in fact it is) coming ſoon to maturity, are eaſily blown over the whole ground; and it is undoubtedly owing to the ſame cauſe, viz. to the remaining diſperſed ſeeds of the preceding year's ſen, that ſome grounds are infeſted with this diſtemper for ſeveral years running. The means pointed out for curing the moſs on fruit-trees ſhould therefore be aſſiduouſly recurred to here, at leaſt ſo far as they can be applied to hops; and, at all events, particular care ſhould be taken to keep the land always in fine tilth, conſtantly free from weeds, and to burn all the fenny hop-vines, in a place remote from the garden, as ſoon as they are picked. We have already ſeen inſtances of the cure of moſs upon fruit-trees, by the uſe of hog's dung; and there is no room to doubt the efficacy of the ſame remedy when applied to mouldy, or moſſy hops.

Mr. Auſten, of Canterbury, obſerves that the ſen is more fatal to thoſe grounds which lie low, and are cloſely ſheltered, than to ſuch as have a high, and open ſituation; to thoſe that lie ſhelving to the north, more than to thoſe whoſe ſlope is towards the ſouth; to the middle of hop-grounds, more than to their outſides, and to dry and light grounds more than to moiſt and ſtiff ſoils. This was very apparent throughout his plantations, where the land was prepared and planted in the ſame manner, and at the ſame time.

The mildew, which lights upon hops, is a white dew, that falls in ſummer at ſun-riſe, chiefly when the hops are in flower. Its fall is ſo unequal, that it ſometimes embraces a whole diſtrict, and ſometimes only parts of it. This dew dries up the hops, withers and conſumes their leaves, and conſequently ruins the crop. "There is," ſay the authors of the Journal Oeconomique, whoſe account

of

of this diſtemper, to which hops are extremely liable, we ſhall copy here, "no other remedy from nature againſt this miſchance, except rain ſufficient to waſh the plant, and clear it entirely from this fatal dew: but as rain ſeldom comes quite ſeaſonably to the relief of the plant thus affected, artificial means have been ſought, for inſuring it againſt this accident. Some have ſurrounded their hop-grounds with hogs-dung; others have employed perſons to go through the ground with veſſels full of beech-aſhes, and to throw them upon the hops while the mildew was falling; and both ſides, profiting by their experience, pretend to have found a ſpecific preſervative againſt the bad effects of the mildew. They have even proceeded ſo far as that each ſide affirm their's to be the only remedy. Thoſe who uſe hog-dung ſay, that the aſhes may probably hinder the action of the dew upon the plant; but that they muſt, at the ſame time, ſtop up its pores, and deprive the ſoil of its humidity; a circumſtance equally ruinous to the plant: and that, beſides, beech is not to be found every where, and if it muſt be brought from afar, the remedy would in ſome meaſure become impracticable, by the ſcarcity and difficulty of procuring it. The partiſans of the aſhes ſay, that they cannot comprehend how hog-dung laid round the hop-ground in the ſpring, ſhould preſerve ſuch virtue as to deſtroy the bad quality of this mildew in the ſummer. In ſhort, to render this diſcuſſion complete, each ſide alledges, that the trials which they have made of the other's remedy did not ſucceed.

"This diſpute, the ſubject of which is highly intereſting to all countries where beer is the common drink, excited a naturaliſt to examine the nature of this mildew; and with the aſſiſtance of a microſcope he perceived it to be full of the eggs of little inſects, which fly in vaſt numbers in the air while the hop is in bloſſom. Theſe inſects gnaw the leaves even of trees, and, like others of their ſpecies, undergo various metamorphoſes. This diſcovery induced him to believe, that, as inſects are not apt to attack perfectly healthy trees, or vigorous plants, but only ſuch as are feeble and ſickly (they being endued with ſuch nice ſenſations as to diſtinguiſh by the outſide only, perhaps by the ſmell, a plant which is vitiated within, though it may appear to us to be quite fair and ſound) hog-dung might probably give ſuch vigour to the hop, as to render theſe little animals afraid to attack it: for it has been remarked, that the inſects which nip a leaf, leave it as ſoon as they find in it an abundant juice, the ſalts of which, it may be preſumed, are too ſtrong for them; and that they fix on thoſe only which begin to decay and loſe their ſap. Aſhes may likewiſe have the power of hurting them, and its ſalts may be capable of giving them diſturbance. But late experience hinders us from giving entire credit to theſe two remedies, and ſhews, that if they have ſometimes preſerved hops from the effects of mildew, we are not to conclude that they will always anſwer this deſirable end.

"A very good huſbandman ſaw his hops ſpoiled by the mildew, notwithſtanding the dung with which they were ſurrounded, and the aſhes that were thrown upon them: in a little time the leaves of the plants were covered with millions of ſmall white inſects. The aſhes, indeed, ſeemed to kill them; but, as was obſerved above, they at the ſame time deprived the ſoil of its neceſſary moiſture. Deſirous of ſaving his hops, he recollected an axiom in medicine, importing, that bitter things kill worms: *amarum necat vermes.* He then ordered a quantity of wormwood to be bruiſed; and having infuſed it in water, he ſprinkled his hops with the infuſion, by means of a forcing pump; but he was too late, the hops being already deſtroyed. A clergyman in his neighbourhood, who was well verſed in matters of agriculture, and to whom he related his bad ſucceſs, anſwered, that when ſuch an accident happened to him, he, without giving himſelf ſo much trouble, ordered his people to ſtrip off immediately all the leaves of his hops, and that, the ſtalks puſhing out other leaves, he had at leaſt one half, and ſometimes two thirds, of his ordinary crop."

"The publication of the above account concerning hops," add the writers of the *Journal Oeconomique* (whom we continue to copy) in one of their ſubſequent papers, "has excited a ſkilful farmer to communicate his experiments on this ſubject. The reader will perceive, by the following extract of his letter, which we are impatient to publiſh to the world, the obligations that are due to him from all thoſe who cultivate hops, and the credit he deſerves in what he relates.

"I was informed ſome years ago, that hogs dung might be employed to great advantage in hop gardens: nevertheleſs, as I could not conceive the reaſon of the advantage which the hops derived from that ſort of dung, I gave myſelf no trouble about uſing it preferably to any other; but having this laſt year loſt almoſt all my hops by the mildew, and having obſerved but one ſingle place where the fruit remained entire, and in a perfect ſtate, I found, upon diligent enquiry, that my ſervants had laid hogs dung upon that very ſpot, preciſely where the mildew had not injured the fruit. I am therefore convinced of the good effects of this dung in hop gardens, and the more ſo, as I am certain that my land was prepared with dung of all ſorts. The farmer will therefore find his account in uſing for his hop grounds all his hogs dung (which, it is likewiſe to be conſidered, is in general thought to be the leaſt ſerviceable to corn lands) and in covering his hop trenches, both in autumn and ſpring, with the ſame kind of dung new, before it is rotten."

The latter part of this latter is calculated for ſuch general utility, that we cannot refrain from adding it here, though at the hazard of digreſſing from the preſent ſubject. The directions given in it are indeed uncommon; but we can hardly ſuppoſe, that the writer of it would inſtance facts, without having a foundation for ſo doing.

"When hops are ſcarce, their leaves and ſprigs ought to be gathered for ſeveral uſeful purpoſes; but they muſt be gathered with great care: no leaves ſhould be taken, but ſuch as are clean, young, whole, and green; and only the tips of the ſprigs that are green, young, and full of juice. They muſt be dried in a very clean and airy place.

"Theſe may be uſed in brewing, for an after-beer, or for common ſmall beer; for by throwing in the leaves and ſprigs of hops, that beer acquires additional ſtrength, becomes the more wholeſome, and will keep the longer.

"The leaves and ſprigs of hops are, during the exceſſive colds of winter, an excellent cordial to cattle, whom they ſtrengthen prodigiouſly. The method of uſing them, is to infuſe them in boiling water, and to mix this infuſion with the ordinary drink of the cattle.

"Cattle may be ſtill more ſtrengthened, by mixing with their drink the tops of pines or firs: and to render theſe the more efficacious, it is proper to boil them in a kettle, that all the reſinous ſubſtances may diſſolve, and

to

to pour the extract into their drink. Some of my cows, then kept on a little farm, which is surrounded with mountains, were so affected by a prodigious cold, that the very marrow was almost frozen in their bones: they lay helpless upon the ground, and though the best of fodder was given them, could not use their limbs or rise up. I can ascribe to no other cause, than the remedy which I have just now pointed out, the surprizing cure of these animals. In one month's time, they were so well recovered, that they rose without any assistance, and ever since they have resisted the most violent cold, without being in the least affected. The singularity of this event determined me to impart it to you, in order that every body may, upon the like occasion, have recourse to the same remedy."

As to the fire-blast, as it is commonly called, we shall only add here, what Dr. Hales had related, that, in the month of July, which is the season when this blight is most apt to affect hops, he had seen the vines in the middle of the hop ground scorched up almost from one end of a large plantation to another, when a hot gleam of sun-shine came immediately after a shower of rain; and that, at such times, vapours may be observed, with the naked eye, to ascend so plentifully, as to make an object, which was before clear and distinct, become immediately very dim and tremulous. It was therefore probably owing to the much greater quantity of vapours in the middle of the hop garden, than there was towards its skirts; and that middle being the densest medium, the rays of the sun may have been collected nearer to a point, by passing through that denser medium, than they were in the outer parts of the ground. The course of the scorch was at right angles to the beams of the sun about eleven o'clock, at which time the hot gleam happened. The hop ground was situated in a valley, running from south-west to north-east; there was very little wind, and that in the course of the scorch.

HOPPER, a kind of basket, in which the seed-corn is carried at the time of sowing. *See the article* DRILL-PLOUGH.

HORN-BEAM, the name of a tree very common in many parts of England, and in some places cultivated for its wood, which is very hard and serviceable for many purposes, especially turnery-ware, mill-cogs, &c.

HORSE, a well known quadruped, and one of the noblest animals we are acquainted with.

The most noble conquest ever obtained by man, was over this proud and spirited animal, which shares with him the fatigues of war, and the glories of battle. The horse, not less intrepid than his master, sees danger, and defies it; he inures himself to the din of arms; he delights in it, seeks it, and is animated with an ardour equal to that of man. He also shares with his master in the pleasures of the chace, the course, and tournaments: but his docility being equal to his courage, he is not carried away by impetuosity; but checks its impulses, and not only submits to the hand of the rider, but seems even willing to consult his desires. Ever obedient to the impressions he receives, he darts forward, slackens his pace, or stops, as they happen to indicate: he renounces his very being, and exists merely by the will of another, which he frequently anticipates, and by the celerity and precision of his motions, at once expresses and executes. He feels as much as is desired, and performs no more than the rider pleases; he gives himself up without reserve. and declines no service; exerts all his strength, and, that his obedience may be complete, will strain every nerve, till he even expires under his generous efforts.

Such is the horse, whose talents are improved, and his natural qualities perfected by art: from his birth he is carefully attended, exercised, and fitted for the service of man: his education commences with the loss of his liberty, and is completed by restraint. The servitude of these animals is so universal and perpetual, that we seldom see them in their natural state. When employed, they are loaded with harness; in the seasons of rest, they are not entirely free from shackles, and even in the fields and pastures, they carry the badges of slavery, and frequently bear the cruel marks of labour and pain. Their mouths disfigured with furrows, occasioned by the bit; their sides deformed with ulcers or cicatrices from the spur; their hoofs perforated with nails, and their attitudes, by the continued pressures of the harness, cramped and constrained; even those, whose servitude is of the easiest kind, being kept chiefly for shew and magnificence, and whose gilded chains are not so much intended for an ornament to them, as to display the opulence of their master, are still more disgraced by the elegance of their foretop, the plaiting of their manes, the gold and silken caparisons with which they are adorned, than by the iron fastened to their feet.

Nature is more elegant than art; and in an animated being, the freedom of motion constitutes the beauty of nature. Observe those horses in the American dominions of Spain, where they enjoy all the sweets of liberty; how elegant in their attitudes, their running and leaping! Free from all restraint and stiffness, they are proud of their independence; they fly from man, and disdain his care; they seek and find themselves proper food; they range and frisk at liberty in immense pastures, cropping the fresh product of a perpetual spring. No settled abode, no other shelter than the canopy of a serene sky, they breathe a purer air than in those vaulted palaces where we confine them in narrow spaces. Accordingly these wild horses excel most of their species in strength, fleetness, and vigour. In them spirit and dignity are the gifts of nature; the other possess only the gifts of art, viz. skill and gracefulness.

The nature of these animals is not ferocious, they are only wild and spirited. Though superior in strength, they never molest other animals; and if molested themselves, they despise, disperse, or trample upon the aggressor. They are attached to each other, and herd together; not through fear, but from a natural love of society. Grass and vegetables being all they desire, a sufficiency of food is never wanting; and not being carnivorous, they have no wars either with other animals, or among themselves. They never dispute about subsistence, never contend with one another for prey or booty, the usual causes of quarrels and battles among carnivorous animals. Thus they live in peace; every individual has enough, and their appetites being simple and moderate, they never envy each other.

All these particulars may be observed in young horses brought up together; their dispositions are mild and gentle, the social qualities are seen in them, and their strength and mettle are conspicuous only in acts of emulation. They strive to excel in speed, and to accustom themselves to danger: they defy each other to cross a river, or leap a ditch; and those which, in these natural exercises, set the

example, thoſe which voluntarily lead the way, are always the beſt, the moſt generous, and often, when tamed, the moſt docile and tractable.

Some antient authors mention wild horſes, and even the places where they were found. Herodotus obſerves, that on the banks of the Hypanis in Scythia, were wild white horſes; and he deſcribes others in the northern parts of Thrace, beyond the Danube, cloathed with hair five inches in length. Ariſtotle mentions Syria; Pliny, the northern countries; Strabo, the Alps and Spain, as countries that produced wild horſes. Among the moderns, Cardan ſays the ſame of Scotland and the Orkneys; Olaus of Muſcovy; Dapper of the iſle of Cyprus, adding, that its wild horſes were remarkable for their beauty, ſwiftneſs and ſtrength; Struys of the iſle of May, where there is a breed of wild horſes extremely ſmall. Leo Africanus relates, that wild horſes were found in the deſarts of Africa and Arabia; and affirms, that he himſelf ſaw, in the waſtes of Numidia, a white colt with a frizzled mane. Marmol confirms this account, and obſerves that in the deſarts of Arabia and Lybia, theſe animals are ſmall, of an aſh colour, and ſome of them white, with ſhort briſtled manes; and that neither dogs nor tame horſes can equal them in fleetneſs. The *Lettres Edifiantes* mention very ſmall wild horſes in China.

All parts of Europe being at preſent inhabited, and almoſt equally peopled, wild horſes are no longer to be found in it; and thoſe in America came originally from tame horſes bred in Europe, and carried over thither by the Spaniards, where they have ſince multiplied in the vaſt tracts of that uninhabited country; for this ſpecies of animals were wanting in the new world. The amazement and terror of the inhabitants of Mexico and Peru, at the ſight of the horſes and the cavalry, ſufficiently intimated to the Spaniards that the horſe was unknown in theſe climates, which induced them to tranſport great numbers both for military ſervice, private convenience, and the propagation of the ſpecies. Some they turned looſe in different iſlands, and even on the continent, where they multiplied like other wild animals. Monſieur de la Salle, in the year 1685, ſaw ſome of theſe horſes near the bay of St. Louis, in North America; but ſo wild that he could not come near them. The author of the adventures of the Buccaniers ſays, "that in the iſland of St. Domingo, troops of above five hundred horſes are often ſeen; that at the ſight of a man they make a general halt, while one of them approaching within a certain diſtance, ſnorts, flies away, and all the reſt follow him." He adds, that whether theſe horſes have degenerated during their being wild, he cannot pretend to ſay; but he did not think them ſo handſome as thoſe of Spain, though undoubtedly of that breed. "Their head and legs, he deſcribes, as very large, the latter full of knots; their ears and neck long. The inhabitants eaſily tame them for their ſeveral employments, and the hunters load them with their hides. They are taken in toils, laid in places where they frequent, are eaſily entangled, and if by the neck, ſtrangle themſelves, unleſs ſome perſon happens to be ready to aſſiſt them. They are faſtened round the body and legs to trees, and there left two days without either meat or drink. This renders them tame, and in time they become as tractable as if they had never been wild: and if they ſhould by accident recover their liberty, they never regain their former wildneſs, but know their maſters, and quietly ſuffer themſelves to be retaken."

This demonſtrates, that theſe animals, naturally mild, are very much inclined to become familiar with man, and attach themſelves to him. Accordingly, none of them are ever ſeen to leave our dwellings for the foreſts and deſarts; but, on the contrary, expreſs the greateſt deſire of returning to their ſtables; though all they meet with there is a groſs food, always the ſame, and generally meaſured out rather by parſimony than their craving appetites; but the kind treatment they meet with compenſates for their other loſſes. When ſpent with fatigue, the place of reſt is a place of delight; they ſmell it from afar; they find it out in the midſt of the moſt crouded cities, and ſeem in every thing to prefer ſervitude to freedom. The habits they have contracted become a kind of ſecond nature; horſes left in the woods having been known to keep a continual neighing, in order to be heard; and at the voice of a man, have ran to him with tranſport; and amidſt a rich variety of agreeable nouriſhment, while deprived of human ſociety, they have been known to loſe their fleſh, and to become ſtrangely emaciated in a very ſhort time.

Thus education gives the whole turn to their manners; and this education requires an aſſiduity, care, and attention, that man will not beſtow on any other creature; but the continual ſervices of the horſe make him ample amends.
